This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ **Make non-commercial use of the files** We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ **Refrain from automated querying** Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ **Maintain attribution** The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ **Keep it legal** Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/)
McCabe Memorial Gift

This book is one of the volumes from the library of the late
Colonel William Gordon McCabe
of Virginia, an alumnus of the University of Virginia,
presented to the University in memory of their father by his sons
William Gordon McCabe
and E.R.Warner McCabe
1924
THE
ENCYCLOPÆDIA BRITANNICA

ELEVENTH EDITION

FIRST edition, published in three volumes, 1768—1771.
SECOND " " ten " " 1777—1784.
THIRD " " eighteen " " 1788—1797.
FOURTH " " twenty " " 1801—1810.
FIFTH " " twenty " " 1815—1817.
SIXTH " " twenty " " 1823—1824.
SEVENTH " " twenty-one " " 1830—1842.
EIGHTH " " twenty-two " " 1853—1860.
NINTH " " twenty-five " " 1875—1889.
TENTH " " ninth edition and eleven supplementary volumes, 1902—1903.
ELEVENTH " " published in twenty-nine volumes, 1910—1911.

INITIALS USED IN VOLUME IX. TO IDENTIFY INDIVIDUAL CONTRIBUTORS, WITH THE HEADINGS OF THE ARTICLES IN THIS VOLUME SO SIGNED.

A. A. T.  
ARThUR Augustus Tilley, M.A.  
Fellow and Lecturer in Modern Languages, King's College, Cambridge. Author of *The Literature of the French Renaissance*; &c.

A. C.  
Arthur Cawley, LL.D., F.R.S.  
See the biographical article: Cawley, Arthur.

A. CH.  
Arthur Cushman McGiffert, M.A., Ph.D., D.D.  
Professor of Church History, Walter Theological Seminary, New York. Author of *History of Christianity in the Apostolic Age*; &c. Editor of the *Historia Ecclesiastica of Eusebius*.

A. E. G.*  
Rev. Alfred Ernest Gayle, M.A., D.D.  
Principal of New College, Hampstead. Member of the Board of Theology and the Board of Philosophy, London University. Author of *Studies in the Inner Life of Jesus*; &c.

A. E. H.  
A. E. Houghton.  
Formerly Correspondent of the Standard in Spain. Author of *Restoration of the Bourbons in Spain*.

A. E. H. L.  
Augustus Edward Hough Love, M.A., D.Sc., F.R.S.  
Sedleian Professor of Natural Philosophy in the University of Oxford. Hon. Fellow of Queen's College. Formerly Fellow of St John's College, Cambridge. Secretary of the London Mathematical Society.

A. Fl.*  
Alexander Fisher.  

A. F. K.  
A. F. Kendrick.  
Keeper of the Victoria and Albert Museum, South Kensington.

A. F. P.  
Fellow of All Souls' College, Oxford. Professor of English History in the University of London. Assistant Editor of the *Dictionary of National Biography*, 1863-1907. Author of *England under the Protector Somerset; Life of Thomas Cranmer*; &c.

A. Go.*  
Rev. Alexander Gordon, M.A.  
Lecturer on Church History in the University of Manchester.

A. H.  
Arthur Hassall, M.A.  
Student and Tutor of Christ Church, Oxford. Author of *A Handbook of European History; The Balance of Power*; &c. Editor of the 3rd edition of T. H. Dyer's *History of Modern Europe*.

A. H. G.  
Alan Henderson Gardner, M.A.  

A. H. S.  
Rev. A. H. Sayce, Litt.D., LL.D.  
See the biographical article: Sayce, A. H.

A. H.-S.  
A. Houton-Smith, C.I.E.  
General in the Persian Army. Author of *Eastern Persian Irak*.

A. J. G.  
Rev. Alexander James Grieve, M.A., B.D.  
Professor of New Testament and Church History at the United Independent College, Bradford. Sometime Registrar of Madras University, and Member of Mysore Educational Service.

A. M.G.  
Allen Mawer, M.A.  
Professor of English Language and Literature, Armstrong College, Newcastle-on-Tyne. Fellow of Gonville and Caius College, Cambridge. Formerly Lecturer in English at the University of Sheffield.

1 A complete list, showing all individual contributors, with the articles so signed, appears in the final volume.
INITIALS AND HEADINGS OF ARTICLES

A. McM. Alexander MacMorran, K.C., M.A.
Bencher of the Middle Temple. Author of works on the Local Government Act 1888; Local Government Act 1894; London Government Act 1899; &c.

A. M. C. Agnes MaryClarke.
See the biographical article: Clarke, A. M.

A. M. Cl. Agnes Muriel Clay (Mrs Wilde).
Formerly Resident Tutor of Lady Margaret Hall, Oxford. Joint Author of Sources of Roman History, 135-70 B.C.

A. N. Alfred Newton, F.R.S.
See the biographical article: Newton, Alfred.

A. Se.* Adam Sedgwick, M.A., F.R.S.
Professor of Geology at the Imperial College of Science and Technology, London, and formerly Tutor, of Trinity College, Cambridge. Professor of Zoology in the University of Cambridge, 1907-1909.

A. S. C. Alan Summerly Cole, C.B.
Assistant Secretary for Art, Board of Education, 1900-1908. Author of Ancient Needlepoint and Pillow Lace; Embroidery, and Lace; Ornament in European Silks; &c.

Former Scholar of St John's College, Oxford. Bacon Scholar of Gray's Inn, 1900.

A. W. R. Alexander Wood Renton, M.A., LL.B.

Author of English Heraldry; A Manual of British Archaeology; &c.

Vice-Chancellor of Sheffield University. H.M.'s Commissioner and Commander-in-Chief for the British East Africa Protectorate; Agent and Consul-General at Zanzibar; Consul-General for German East Africa, 1900-1904. Former Fellow of Trinity College, Oxford. Author of Turkey in Europe; Letters from the Far East; &c.

C. E. N. R. Charles Edmund Newton Robinson, M.A.

C. F. B. Charles Francis Bastable, M.A., LL.D.
Regius Professor of Law and Professor of Political Economy in the University of Dublin. Author of Public Finance; Commerce of Nations; Theory of International Trade.

C. H. Ha. Carlton Huntley Hayes, A.M., Ph.D.
Assistant Professor of History in Columbia University, New York City. Member of the American Historical Association.

Chief Professor of Modern History, Oxford University. Fellow of All Souls' College. Fellow of the British Academy. Corresponding Member of the Madrid Academia de la Historia. Author of The Art of War in the Middle Ages; The Great Revoil of 1758; Warwick the King-maker; &c.

D. G. H. David George Hogarth, M.A.
Keeper of the Ashmolean Museum, and Fellow of Magdalen College, Oxford. Fellow of the British Academy. Escavated at Taphos, 1888; Naukratis, 1893 and 1903; Ephesus, 1904-1905; Assiut, 1906-1907; Director, British School at Athens, 1897-1900; Director, Cretan Exploration Fund, 1899.

D. H. David Hannay.
Formerly British Vice-Consul at Barcelona. Author of Short History of Royal Navy, 1217-1888; Life of Emilio Castelar; &c.

D. J. M. D. J. Matthews.
Hydrographer, Laboratory of the Marine Biological Association of the United Kingdom, Plymouth.

Extra Groom of the Bedchamber to H.M. King George V. Director of the Foreign Department of The Times, 1891-1899. Member of Institut de Droit International and Office de l'Instruction Publique de France. Joint Editor of New Volumes (1868 ed.) of the Encyclopaedia Britannica. Author of Russia; Egypt and the Egyptian Question; The Web of Empire; &c.

D. S. M.* David Samuel Mangiroll, M.A., D.Litt.
Laudian Professor of Arabic, Oxford. Fellow of New College. Author of Arabic Papry of the Bodleian Library; Mohammed and the Rise of Islam; Cairo, Jerusalem and Damascus.

See the biographical article: WALLACE, WILLIAM (1820-1895).

W. W.  WILLISTON WALKER, PH.D., D.D.
Professor of Church History, Yale University. Author of History of the Congregational Churches in the United States; The Reformation; John Calvin; &c.

PRINCIPAL UNSIGNED ARTICLES

EDWARDES, SIR HERBERT BENJAMIN (1819-1888), English soldier-statesman in India, was born at Frodesley in Shropshire on the 12th of November 1819. His father was Benjamin Edwardes, rector of Frodesley, and his grandfather Sir John Edwardes, baronet, eighth holder of a title conferred on one of his ancestors by Charles I. in 1644. He was educated at a private school and at King's College, London. Through the influence of his uncle, Sir Henry Edwardes, he was nominated in 1840 to a cadetship in the East India Company; and on his arrival in India, at the beginning of 1841, he was posted as ensign in the 1st Bengal Fusiliers. He remained with this regiment about five years, during which time he mastered the lessons of his profession, obtained a good knowledge of Hindustani, Hindi and Persian, and attracted attention by the political and literary ability displayed in a series of letters which appeared in the Delhi Gazette.

In November 1845, on the breaking out of the first Sikh War, Edwardes was appointed aide-de-camp to Sir Hugh (afterwards Viscount) Gough, then commander-in-chief in India. On the 18th of December he was severely wounded at the battle of Mudki. He soon recovered, however, and fought by the side of his chief at the decisive battle of Sobraon (February 10, 1846). He was soon afterwards appointed third assistant to the commissioners of the trans-Sutlej territory; and in January 1847 was named first assistant to Sir Henry Lawrence, the resident at Lahore. Lawrence became his great exemplar and in later years he was accustomed to attribute to the influence of this "father of his public life" whatever of great or good he himself achieved. He took part with Lawrence in the suppression of a religious disturbance at Lahore in the spring of 1846, and soon afterwards assisted him in reducing, by a rapid movement to Jammu, the conspirator Imam-ud-din. In the following year a more difficult task was assigned him—the conduct of an expedition to Bannu, a district on the Waziri frontier, in which the people would not tolerate the presence of a collector, and the revenue had consequently fallen into arrear. By his rare tact and fertility of resource, Edwardes succeeded in completely conquering the wild tribes of the valley without firing a shot, a victory which he afterwards looked back upon with more satisfaction than upon others which brought him more renown. His fiscal arrangements were such as to obviate all difficulty of collection for the future. In the spring of 1848, in consequence of the murder of Mr vans Agnew and Lieutenant Anderson at Multan, by order of the diwan Mulraj, and of the raising of the standard of revolt by the latter, Lieutenant Edwardes was authorized to march against him. He set out immediately with a small force, occupied Leiah on the left bank of the Indus, was joined by Colonel van Cortlandt, and, although he could not attack Multan, held the enemy at bay and gave a check at the critical moment to their projects. He won a great victory over a greatly superior Sikh force at Kinyeri (June 18), and received in acknowledgment of his services the local rank of major. In the course of the operations which followed near Multan, Edwardes lost his right hand by the explosion of a pistol in his belt. On the arrival of a large force under General Whish the siege of Multan was begun, but was suspended for several months in consequence of the desertion of Shere Singh with his army and artillery. Edwardes distinguished himself by the part he took in the final operations, begun in December, which ended with the capture of the city on the 4th of January 1849. For his services he received the thanks of both houses of parliament, was promoted major by brevet, and created C.B. by special statute of the order. The directors of the East India Company conferred on him a gold medal and a good service pension of £100 per annum.

After the conclusion of peace Major Edwardes returned to England for the benefit of his health, married during his stay there, and wrote and published his fascinating account of the scenes in which he had been engaged, under the title of A Year on the Punjab Frontier in 1848-1849. His countrymen gave him fitting welcome, and the university of Oxford conferred on him the degree of D.C.L. In 1851 he returned to India and resumed his civil duties in the Punjab under Sir Henry Lawrence. In November 1853 he was entrusted with the responsible post of commissioner of the Peshawar frontier, and this he held when the Mutiny of 1857 broke out. It was a position of enormous difficulty, and momentous consequences were involved in the way the crisis might be met. Edwardes rose to the height of the occasion. He saw as if by inspiration the facts and the needs, and by the prompt measures which he adopted he rendered a service of incalculable importance, by effecting a reconciliation with Afghanistan, and securing the neutrality of the amir and
EDWARDS, AMELIA—EDWARDS, HENRY

the frontier tribes during the war. So effective was his procedure for the safety of the border that he was able to raise a large force in the Punjab and send it to co-operate in the siege and capture of Delhi. In 1859 Edwards once more went to Kothari, and so effectually was his health so greatly impaired by the continual strain of arduous work that it was doubtful whether he could ever return to India. During his stay he was created K.C.B., with the rank of brevet colonel; and the degree of L.L.D. was conferred upon him by the university of Cambridge. Early in 1862 he again sailed for India, and was appointed commissioner of Umballa and agent for the Cis-Sutlej states. He had been offered the governorship of the Punjab, but on the ground of failing health had declined it. In February 1864, he was compelled to finally resign his post and return to England. A second good service pension was at once conferred on him; in May 1866 he was created K.C. of the Star of India; and early in 1868 was promoted major-general in the East Indian Army. He had been for some time engaged on a life of Sir Henry Lawrence, and high expectations were formed of the work; but he did not live to complete it, and after his death it was put into the hands of Mr Herman Merivale. He died in London on the 23rd of December 1868.

Great in council and great in war, he was singularly beloved by his friends, generous and unselfish to a high degree, and a man of deep religious convictions.

EDWARDS, AMELIA ANN BLOODFORD (1831-1892), English author and Egyptologist, the daughter of one of Wellington's officers, was born in London on the 7th of June 1831. At a very early age she displayed considerable literary and artistic talent. She became a contributor to various magazines and newspapers, and besides many miscellaneous works she wrote eight novels, the most successful of which were Debenham's Vow (1870) and Lord Brackenbury (1880). In the winter of 1873-1874 she visited Egypt, and was profoundly impressed by the new openings for archaeological research. She learnt the hieroglyphic characters, and made a considerable collection of Egyptian antiquities. In 1877 she published A Thousand Miles up the Nile, with illustrations by herself. Convinced that only by proper scientific investigations could the wholesale destruction of Egyptian antiquities be avoided, she devoted herself to arousing public opinion on the subject, and ultimately, in 1882, was largely instrumental in founding the Egypt Exploration Fund, of which she was the first honorary secretary with Reginald Stuart Poole. For the business of this Fund she abandoned her other literary work, writing only on Egyptology. In 1885-1889 she went on a lecturing tour in the United States. The substance of her lectures was published in volume form in 1891 as Pharaohs, Felahs, and Explorers. She died at Weston-super-Mare, Somerset, on the 15th of April 1892, bequeathing her valuable collection of Egyptian antiquities to University College, London, together with a sum to found a chair of Egyptology. Miss Edwards received, shortly before her death, a civil list pension from the British government.

EDWARDS, BELA BATES (1802-1852), American man of letters, was born at Southampton, Massachusetts, on the 4th of July 1802. He graduated at Amherst College in 1824, was a tutor there in 1827-1828, graduated at Andover Theological Seminary in 1830, and was licensed to preach. From 1828 to 1833 he was assistant secretary of the American Education Society (organized in Boston in 1815 to assist students for the ministry), and from 1833 to 1842 was editor of the society's organ, which after 1831 was called the American Quarterly Register. He also founded (in 1833) and edited the American Quarterly Observer; in 1836-1841 edited the Biblical Repository (after 1837 called the American Biblical Repository) with which the Observer was merged in 1835; and was editor-in-chief of the Biblical Repository from 1844 to 1851. In 1848 he became professor of Hebrew at Andover, and from 1848 until his death was associate professor of sacred literature there. He died at Athens, Georgia, on the 20th of April 1852. Among his numerous publications were A Missionary Gazerter (1831), A Biography of Self-Taught Men (1834), a once widely known Eulogic Reader (1835), an English translation, with Samuel Harvey Taylor (1809-1871), of Kühner's Schulgrammatik der Griechischen Sprache and Classical Studies (1844), essays in ancient literature and art written in collaboration with Barnas Sears and C. C. Felton.

EDWARDS' Addresses and Sermons, with a memoir by Rev. Edwards A. Park, were published in two volumes at Boston in 1853.

EDWARDS, BRYAN (1743-1800), English politician and historian, was born at Westbury, Wiltshire, on the 21st of May 1743. His father died in 1756, when his maintenance and education were undertaken by his uncle, Zachary Bayly, a wealthy merchant of Jamaica. About 1759 Bryan went to Jamaica, and joined his uncle, who engaged a private tutor to complete his education, and when Bayly died his nephew inherited his wealth, succeeding also in 1773 to the estate of another Jamaica resident named Hume. Edwards soon became a leading member of the colonial assembly of Jamaica, but in a few years he returned to England, and in 1789 failed to secure a seat in parliament as member for Chichester. He was again in Jamaica from 1787 to 1792, when he settled in England as a West India merchant, making in 1795 another futile attempt to enter parliament, on this occasion as the representative of Southampton.

In 1796, however, he became member of parliament for Grampound, retaining his seat until his death at Southampton on the 15th or 16th of July 1800. In general Edwards was a supporter of the slave trade, and was described by William Wilberforce as a powerful opponent. By his wife, Martha, daughter of Thomas Phipps of Westbury, he left an only son, Hume.

In 1784 Edwards wrote Thoughts on the late Proceedings of Government respecting the Trade of the West India Islands with the United States of America, in which he attacked the restrictions placed by the government upon trade with the United States.

In 1793 he published in two volumes his great work, History, Civil and Commercial, of the British Colonies in the West Indies, and in 1797 published his Historical Survey of the French Colony in the Island of St Domingo. In 1802 a new edition of both these works with certain additions was published in three volumes under the title of History of the British Colonies in the West Indies. This has been translated into German and parts of it into French and Spanish, and a fifth edition was issued in 1819. When Mungo Park returned in 1796 from his celebrated journey in Africa, Edwards, who was secretary of the Association for Promoting the Discovery of the Interior Parts of Africa, came upon Park's narrative as an account of his travels, which was published by the association in their Proceedings; and when Park wrote an account of his journeys he availed himself of Edwards' assistance. Edwards also wrote some poems and some other works relating to the history of the West Indies.

He left a short sketch of his life which was prefixed to the edition of the History of the West Indies, published in 1801.

EDWARDS, GEORGE (1663-1733), English naturalist, was born at Stratford, Essex, on the 3rd of April 1663. In his early years he travelled extensively over Europe, studying natural history, and gained some reputation for his coloured drawings of animals, especially birds. In 1733, on the recommendation of Sir Hans Sloane, he was appointed librarian to the Royal College of Physicians in London. In 1743 he published the first volume of his History of Birds, the fourth volume of which appeared in 1751, and three supplementary volumes, under the title Gleanings of Natural History, were issued in 1755, 1760 and 1764. The two works contain engravings and descriptions of more than 500 subjects in natural history not before described or delineated. He likewise added a general index in French and English, which was afterwards supplied with Linnaean names by Linnaeus himself, with whom he frequently corresponded. About 1764 he retired to Plaistow, Essex, where he died on the 23rd of July 1773. He also wrote Essays of Natural History (1770) and Elements of Botany (1779).

EDWARDS, HENRY THOMAS (1837-1884), Welsh divine, was born on the 6th of September 1837 at Llanymawddwy,
EDWARDS, JONATHAN

Merioneth, where his father was vicar. He was educated at Westminster and at Jesus College, Oxford (B.A., 1860), and after teaching for two years at Llandovery went to Llangollen as his father’s curate. He became vicar of Aberedw in 1866 and of Carnarvon in 1869. Here he began his lifelong controversy with Nonconformity, and became, as representative of the distant family of the Rev. E. Herber Evans (Congregationalist). In 1870 he fought in vain for the principle of all-round denominationalism in the national education system, and in the same year addressed a famous letter to Mr Gladstone on “The Church of the Cymry,” pointing out that the success of Nonconformity in Wales was largely due to “the withering effect of an alien episcopate.” One immediate result of this was the appointment of the Welshman Joshua Hughes (1807-1880) to the vacant see of St Asaph. Edwards became dean of Bangor in 1876 and at once set about restoring the cathedral, and he promoted a clerical education society for supplying the diocese with educated Welsh-speaking clergy. He was a popular preacher and an earnest patriot; his chief defect was a lack of appreciation of the theological attainments of Nonconformity, and a Welsh commentary on St Matthew, which he had worked at for many years and published in two volumes in 1883, was severely handled by a Bangor Calvinistic Methodist minister. Edwards suffered from overwork and insomnia and a Mediterranean cruise in 1883 failed to restore his health; and he died by his own hand on the 24th of May 1884 at Ruabon.

See V. Morgan, Welsh Religious Leaders in the Victorian Era.

EDWARDS, JONATHAN (1723-1758), American theologian and philosopher, was born on the 5th of October 1705 at East (now South) Windsor, Connecticut. His earliest known ancestor was Richard Edwards, Welsh by birth, a London clergyman in Elizabeth’s reign. His father Timothy Edwards (1660-1738), son of a prosperous merchant of Hartford, had graduated at Harvard, was minister at East Windsor, and eked out his salary by tutoring boys for college. His mother, a daughter of the Rev. Solomon Stoddard, of Northampton, Mass., seems to have been a woman of unusual mental gifts and independence of character. Jonathan, the only son, was the fifth of eleven children. The boy was trained for college by his father and by his elder sisters, who all received an excellent education. When ten years old he wrote a semi-humorous tract on the immateriality of the soul; he was interested in natural history, and at the age of twelve wrote a remarkable essay on the habits of the “flying spider.” He entered Yale College in 1716, and in the following year became acquainted with Locke’s Essay, which influenced him profoundly. During his college course he kept note books labelled “The Mind,” “Natural Science” (containing a discussion of the atomic theory, &c.), “The Scriptures” and “Miscellanies,” had a grand plan for a work on natural and mental philosophy, and drew up for himself rules for its composition. Even before his graduation in September 1720 as valedictorian and head of his class, he seems to have had a well formulated philosophy. The two years after his graduation he spent in New Haven studying theology. In 1722-1723 he was for eight months stated supply of a small Presbyterian church in New York city, which invited him to remain, but he declined the call, spent two months in study at home, and then in 1724-1726 was one of the two tutors at Yale, earning for himself the name of “a pillar tutor” by his steadfast loyalty to the college and its orthodox teaching at the time when Yale’s rector (Cutler) and one of her tutors had gone over to the Episcopal Church.

The years 1727 to 1726 are partially recorded in his diary and in the resolutions for his own conduct which he drew up at this time. He was always more an eager soul than an earnest one, not fully satisfied as to his own “conversion” until an experience in his last year in college, when he lost his feeling that the election of some to salvation and of others to eternal damnation was “a horrible doctrine,” and reckoned it “exceedingly pleasant, bright and sweet.” He now took a great and new joy in the beauties of nature, and delighted in the allegorical interpretation of the Song of Solomon. Balancing these mystic joys is the stern tone of his Resolutions, in which he is almost ascetic in his eagerness to live earnestly and soberly, to waste no time, to maintain the strictest temperance in eating and drinking.

On the 15th of February 1727 he was ordained minister at Northampton and assistant to his grandfather, Solomon Stoddard. He was a student minister, not a visiting pastor, his ministerial life being prolonged by the Rev. Mr. Royston, and lasted only thirteen hours of the New Year. He married Sarah Pierrpont, then aged seventeen, daughter of James Pierrpont (1659-1714), a founder of Yale, and through her mother great-granddaughter of Thomas Hooker. Of her piety and almost nun-like love of God and belief in personal love for her, Edwards had known when she was only thirteen, and had written of it with spiritual enthusiasm; she was of a bright and cheerful disposition, a practical housekeeper, a model wife and the mother of his twelve children. Solomon Stoddard died on the 11th of February 1729, leaving to his grandson the difficult task of the sole ministerial charge of one of the largest and wealthiest congregations in the colony, and one proud of its morality, its culture and its reputation.

In 1731 Edwards preached at Boston the “Public Lecture” afterwards published under the title God Glorified in Man’s Dependence. This was his first public attack on Arminianism. The leading thought was God’s absolute sovereignty in the work of redemption: that while it behoved God to create man holy, it was of His “good pleasure” and “mere and arbitrary grace” that any man was now made holy, and that God might deny this grace without any disparagement to any of His perfections. In 1733 a revival of religion began in Northampton, and reached such intensity in the winter of 1734 and the following spring as to threaten the business of the town. In six months nearly three hundred were admitted to the church. The revival gave Edwards an opportunity of studying the process of conversion in all its phases and varieties, and he recorded his observations with psychological minuteness and discrimination in A Faithful Narrative of the Surprising Work of God in the Conversion of Many Hundred Souls in Northampton (1737). A year later he published Discourses on Various Important Subjects, the five sermons which had proved most effective in the revival, and of these none, he tells us, was so immediately effective as that on the Justice of God in the Damnation of Sinners, from the text, “That every mouth may be stopped.” Another sermon, published in 1734, on the Reality of Spiritual Light set forth what he regarded as the inner, moving principle of the revival, the doctrine of a “special” grace in the immediate and supernatural divine illumination of the soul. In the spring of 1735 the movement began to subside and a reaction set in. But the relapse was brief, and the Northampton revival, which had spread throughout the Connecticut valley and whose fascinations reached England and Scotland, was followed in 1739-1740 by the Great Awakening, distinctively under the leadership of Edwards. The movement met with no sympathy from the orthodox leaders of the church. In 1741 Edwards published in its defence The Distinguishing Marks of a Work of the Spirit of God, dealing particularly with the phenomena most criticized, the swoonings, outcries and convulsions. These “bodily effects,” he insisted, were not “distinguishing marks” of the work of the Spirit of God; but so bitter was the feeling against the revival in the more strictly Puritan churches that in 1742 he was forced to write a second apology, Thoughts on the Revival in New England, his main argument being the great moral improvement of the country. In the same pamphlet he defends an appeal to the emotions, and advocates preaching terror when necessary, even to children, who in God’s sight “are young virgins . . . if not Christ’s.” He considered “bodily effects” incidental to the real work of God; but so bitter was the feeling against the revival in the more strictly Puritan churches that in 1742 he was forced to write a second apology, Thoughts on the Revival in New England, his main argument being the great moral improvement of the country. In the same pamphlet he defends an appeal to the emotions, and advocates preaching terror when necessary, even to children, who in God’s sight “are young virgins . . . if not Christ’s.” He considered “bodily effects” incidental to the real work of God; but so bitter was the feeling against the revival in the more strictly Puritan churches that in 1742 he was forced to write a second apology, Thoughts on the Revival in New England, his main argument being the great moral improvement of the country.
various parts of the land." In spite of Edwards's able pamphlet, the impression had become widespread that "bodily effects" were recognized by the promoters of the Great Awakening as the true test of conversion. To offset this feeling Edwards 1 preached at Northampton during the years 1742 and 1743 a series of sermons published under the title of Religious Affections (1746), a restatement in a more philosophical and general tone of his ideas as to "distinguishing marks." In 1747 he joined the movement started in Scotland called the "concern in prayer," and in the same year published An Humble Attempt to Promote Explicit Agreement and Visible Union of God's People in Extra-Clinical Prayer for the Revival of Religion and the Advancement of Christ's Kingdom on Earth. In 1748 he published a memoir of David Brainerd; the latter had lived in his family for several months, had been constantly attended by Edwards's daughter Jerusha, to whom he had been engaged to be married, and had died at Northampton on the 7th of October 1747; and he had been a case in point for the theories of conversion held by Edwards, who had made elaborate notes of Brainerd's conversations and confessions.

In 1748 there had come a crisis in his relations with his congregation. The Half-Way Covenant adopted by the synods of 1657 and 1662 had made baptism alone the condition to the civil privileges of church membership, but not of participation in the sacrament of the Supper. Edwards's grandfather and predecessor, Solomon Stoddard, had been even more liberal, holding that the Supper was a converting ordinance and that baptism was a sufficient test of the privileges of the church. As early as 1744 Edwards, in his sermons on the Religious Affections, had plainly intimated his dislike of this practice. In the same year he had published in a church meeting the names of certain young people, members of the church, who were suspected of reading improper books, 2 and also the names of those who were to be called as witnesses in the case. But witnesses and accused were not distinguished on this list, and the congregation was in an uproar. A great many, fearing a scandal, now opposed an investigation which all had previously favored. Edwards's preaching became unpopular; for four years no candidate presented himself for admission to the church; and when one did in 1748, and was met with Edwards's formal but mild and gentle tests, as expressed in the Distinguishing Marks and later in Qualifications for Full Communion (1749) the candidate refused to submit to them; the church backed him and the break was complete. Even permission to discuss his views in the pulpit was refused, and the ecclesiastical council voted by 10 to 9 that the pastoral relation be dissolved. The church by a vote of more than 200 to 23 ratified the action of the council, and finally a town meeting voted that Edwards should not be allowed to occupy the Northampton pulpit, though he did this on occasion as late as May 1755. He evinced no rancour or spite; his "Farewell Sermon" was dignified and temperate; nor is it to be ascribed to chagrin that in a letter to Scotland after his dismissal he expresses his preference for Presbyterian to Congregational church government. His position at the time was not unpopular throughout New England, and it is needless to say that his doctrine that the Lord's Supper is not a cause of regeneration and that communicants should be professing Christians has since (very largely through the efforts of his pupil Joseph Bellamy) become a standard of New England Congregationalism.

Edwards, with his large family was now thrown upon the world, but offers of aid quickly came to him. A parish in Scotland could have been procured, and he was called to a Virginia church. He declined both, to become in 1750 pastor of the church in Stockbridge and a missionary to the Housatonic Indians. To the Indians he preached through an interpreter, and their interests he boldly and successfully defended by attacking the whites who were using their official position among them to increase their private fortunes. In Stockbridge he wrote the Humble Rhetoric, also called Reply to Williams (1752), which was an answer to Solomon Williams (1700-1756), a radical and a bitter opponent of Edwards as to the qualifications for full communion; and he there composed the treatises on which his reputation as a philosophical theologian chiefly rests, the essay on Original Sin, the Dissertation concerning the Nature of True Virtue, the Dissertation concerning the End for which God Created the World, and the great work on the Will, written in four months and a half, and published in 1754 under the title, An Inquiry into the Laws Preserving Nature Respecting the Freedom of the Will which is supposed to be Essential to Moral Agency.

In 1757, on the death of President Burr, who five years before had married Edwards's daughter Esther, he reluctantly accepted the presidency of the College of New Jersey (now Princeton University), where he was installed on the 16th of February 1758. Almost immediately afterwards he was inoculated for smallpox, which was raging in Princeton and vicinity, and, always feeble, he died of the inoculation on the 28th of March 1758. He was buried in the old cemetery at Princeton. He was slender and fully six feet tall, with his own gentle, almost feminine face looked the scholar and the mystic.

The Edwardsian System.—It is difficult to separate Edwards's philosophy from his theology, except as the former is contained in the early notes on the Mind, where he says that matter exists only in so far as space is there, and that only are real; that in metaphysical strictness there is no being but God; that the greatest is the greatest and only good; and that God as infinite entity, wherein the agreement of being with being is absolute, is the supreme exemplum of the supreme good. Not so with the supreme principle of the universe. We are independent of Berkeley and Malebranche, and were not drawn from Arthur Collier's Clavis universalis (1713), with which they have a point in common, but so far suggested, in point of argument, by Cowper, Newton, and Matz, that the doctrine of ideas, Newton's theory of colours, and Clowthworth's Platonism, with all of which Edwards was early familiar. But they were never developed systematically, and the conception of the supreme principle of the universe here and now for its own sake, does not appear in any of his writings. The fundamental metaphysical postulate that being and God are ultimately identical remained, however, the philosophical basis of all his thinking, and reverence for this being as the supreme good remained the fundamental disposition of his mind. That he did not interpret this idea in a Spinozistic sense was due to his more spiritual conception of "being" and to the reaction on his philosophy of his theology. The theological interest, indeed, came in the end to predominate, and philosophy to appear as an instrument for the defence of Calvinism. But even here one of the most characteristic traits is the strong ethical motive: instead of being elaborated on purely rational principles, it is mixed up with a system of theological conceptions with which it is never entirely combined, it is expressed in the light of the great religious effects of theological controversy. Moreover, of one of his most central convictions, that of the sovereignty of God in election, he confesses that he could give it no adequate philosophical or psychological justification.

Edwards's reputation as a thinker is chiefly associated with his treatise on the Will, which is still sometimes called "the one large contribution that America has made to the deeper philosophy of the thought of the world." The aim of this treatise was to refute the doctrine of free-will, since he considered it the logical, as distinguished from the sentimental, ground of most of the Arminian objections to Calvinism. He defines the will as that by which the "mind chooses anything." To act voluntarily, he says, is to act electively. So far he and his opponents are agreed. But choice, he holds, is not arbitrary; it is determined in every case by "that motive which as momentary and arbitrary in the view of God is the strongest and that motive is strongest which presents in the immediate object of volition the greatest apparent good," that is, the greatest degree of agreeable-nonsuffering. What is given in this case is a set of circumstances, external and internal, all contributing to form the "cause" of which the voluntary act and its consequences are seen to proceed. Edwards contends that this external cause and effect here is as "sure and perfect" as in the realm of physical nature and constitutes a "necessity." He reduces the opposite doctrine to three assumptions, all of which he shows to be invalid: (1) "a self exists which has the power to will absolutely; (2) a self is such that there is no difference..., that the mind previous to the act of volition (is) in equilibriu"; (3) "contingency... as opposed to... any fixed and certain connexion with some previous ground or reason for its existence." Although he denies liberty to the will in this sense—indeed, strictly speaking, neither liberty nor necessity, he says, is properly applied to the will, "for the will itself is not an agent that has a will"—he nevertheless insists that the subject will is a free moral agent, and argues that without the

1 Edwards recognized the abuse of impulses and impressions, opposed itinerant and lay preachers, and defended a well-ordered and well-educed clergy.

2 These were probably not fiction like Pamela, as Sir Leslie Stephen suggested, for Edwards listed several of Richardson's novels for his own reading, and considered Sir Charles Grandison a very moral and excellent work.
determine connexion between volition and motive which he asserts and the liberty he holds, is simply freedom from constraint, "the power ... that any one has to do as he please." This power man pos-

ses.

And that the right or wrong of choice depends not on the causation or its nature, but on the individual, the acts by which Christ, whose acts were necessarily holy, yet truly virtuous, praising

worthy and rewarded. Even God Himself, Edwards here main-
tains, is not, in this way, to carry to, to carry with constraint. His will, wisdom and inclination.

There is no necessary connexion between Edward's doctrine of the motive and the psychical, in the Pantheist, in the deist, in the trinitarian in any connected, and the trinitarianism with us is not congruent. Similar doctrines have more frequently perhaps been associated with theological scepticism. But for him the alternative was between Calvinism and Arminianism, simply because of the historical fact that he have found in the reform of Arminiation, the assumptions common to both sides of the controversy, he must be con-

sidered completely successful. As a general argument his acumen, his power, beneficent being a so wide object, his position in the

abstract conception of the will and in his inadequate, but suggestive, treatment of causation, in regard to which he anticipates in important respects the doctrine of Hume. Instead of making the motive to

cause, and the means of its occurrence, to the other on his case, it is a long way beyond the abstraction in which his opponents stuck, that of a bare faculty without any assignable content. Modern psychol-

ogy has strengthened the conception for a fixed connexion between

motility and mental functions, and unconnected processes of which Edwards, who thought that nothing could affect the mind which was unperceived, little dreamed; at the same time, at the same time, the development of natural and organic conceptions, it has had much in the other forms of statement obsolete, and has given a new meaning to the ideas of formation, which, as applied to an absolute power, Edwards rightly rejected as absurd.

Edwards's controversy with the Arminians was continued in the essay on Original Sin, which was in the press at the time of his death. This essay is with Augustinians, with the Trinitarian conf-

ession by arguing, consistently with his theory of the Will, that Adam had no more freedom of will than we have, but had a special endowment of natural gifts of grace by which he rebuked the notion that God was lost, and that this gift was withdrawn from his disciples, not because of any fictitious imputation of guilt, but because of their real state of guilt in his actual identity with him in his transgression.

The Dissertation on the Nature of True Virtue, pochtmously published, is justly regarded as one of the most original works on ethics of the 18th century, and is the process of volition, producing it as a cause antecedent to the exercise of a special mental faculty. Yet his conception of this faculty as functioning only in and through motility, and most, on the contrary, is certainly capable of a long way beyond the abstraction in which his opponents stuck, that of a bare faculty without any assignable content. Modern psychol-

ogy has strengthened the conception for a fixed connexion between

motility and mental functions, and unconnected processes of which Edwards, who thought that nothing could affect the mind which was unperceived, little dreamed; at the same time, at the same time, the development of natural and organic conceptions, it has had much in the other forms of statement obsolete, and has given a new meaning to the ideas of formation, which, as applied to an absolute power, Edwards rightly rejected as absurd.

cession by arguing, consistently with his theory of the Will, that Adam had no more freedom of will than we have, but had a special endowment of natural gifts of grace by which he rebuked the notion that God was lost, and that this gift was withdrawn from his disciples, not because of any fictitious imputation of guilt, but because of their real state of guilt in his actual identity with him in his transgression.

Edwards's main aim had been to revivify Calvinism, modifying it for the needs of the time, and to promote a warm and vital Christian piety. The tendency of his successors was—to state the matter mildly—to take some of his theories and twist them into the most extreme. Of his immediate followers Joseph Bellamy is distinctly Edwardian in the keen logic and in the spirit of his True Religion Dissolved, but he breaks with his master in his theory of general (not limited) atonement. Samuel Hopkins laid even greater stress than Edwards on the theorem that virtue consists in disinterested benevolence; but he went counter to Edwards in holding that uncondi-

tional resignation to God's decrees, or perhaps it was the original reason why the essay was not published.

Though so typically a scholar and abstract thinker on the one hand, he was, in consequence, as often perceived, little dreamed; at the same time, at the same time, the development of natural and organic conceptions, it has had much in the other forms of statement obsolete, and has given a new meaning to the ideas of formation, which, as applied to an absolute power, Edwards rightly rejected as absurd.

Though so typically a scholar and abstract thinker on the one hand, he was, in consequence, as often perceived, little dreamed; at the same time, at the same time, the development of natural and organic conceptions, it has had much in the other forms of statement obsolete, and has given a new meaning to the ideas of formation, which, as applied to an absolute power, Edwards rightly rejected as absurd.

Edwards's controversy with the Arminians was continued in the essay on Original Sin, which was in the press at the time of his death. This essay is with Augustinians, with the Trinitarian conf-

cession by arguing, consistently with his theory of the Will, that Adam had no more freedom of will than we have, but had a special endowment of natural gifts of grace by which he rebuked the notion that God was lost, and that this gift was withdrawn from his disciples, not because of any fictitious imputation of guilt, but because of their real state of guilt in his actual identity with him in his transgression.

The Dissertation on the Nature of True Virtue, pochtmously published, is justly regarded as one of the most original works on ethics of the 18th century, and is the process of volition, producing it as a cause antecedent to the exercise of a special mental faculty. Yet his conception of this faculty as functioning only in and through motility, and most, on the contrary, is certainly capable of a long way beyond the abstraction in which his opponents stuck, that of a bare faculty without any assignable content. Modern psychol-

ogy has strengthened the conception for a fixed connexion between

motility and mental functions, and unconnected processes of which Edwards, who thought that nothing could affect the mind which was unperceived, little dreamed; at the same time, at the same time, the development of natural and organic conceptions, it has had much in the other forms of statement obsolete, and has given a new meaning to the ideas of formation, which, as applied to an absolute power, Edwards rightly rejected as absurd.

Edwards's controversy with the Arminians was continued in the essay on Original Sin, which was in the press at the time of his death. This essay is with Augustinians, with the Trinitarian conf-

cession by arguing, consistently with his theory of the Will, that Adam had no more freedom of will than we have, but had a special endowment of natural gifts of grace by which he rebuked the notion that God was lost, and that this gift was withdrawn from his disciples, not because of any fictitious imputation of guilt, but because of their real state of guilt in his actual identity with him in his transgression.
EDWARDS, LEWIS—EDWARDS, RICHARD

EDWARDS, LEWIS (1809-1887), Welsh Nonconformist divine, was born in the parish of Llanbadarn Fawr, Cardiganshire, on the 27th of October 1809. He was educated at Aberystwyth and at Llangeliog, and then kept school at these places. In 1828 he went to London to take advantage of the newly-opened university. In 1832 he settled as minister at Laugharne in Carmarthenshire, and in the following year went to Edinburgh, where a special resolution of the senate allowed him to graduate at the end of his third session. He was now better able to further his plans for providing a trained ministry for his church. Previously, the success of the Methodist preachers had been due mainly to their natural gifts. Edwards made his home at Laugharne in 1837, with David Charles, his brother-in-law, he opened a school, which ultimately became the denominational college for north Wales. He died on the 110th of July 1887.

Edwards may fairly be called one of the makers of modern Wales. Through his hands there passed generation after generation of preachers, who carried his influence to every corner of the principality. By fostering competitive meetings and by founding such projects as the New Church concern, the Welsh Times, and a quarterly magazine which he founded in 1845 and edited for ten years, he did much to inform and educate his countrymen on literary and theological subjects. A new college was built at Bala in 1867, for which he raised £10,000. His chief publication was a noteworthy book on The Doctrine of the Attonement, in the form of a dialogue between master and pupil; the treatise is forensic, and emphasis is laid on merit. It was due to him that the North and South Wales Calvinistic Methodist Associations united to form an annual General Assembly; he was its moderator in 1856 and again in 1876. He was successful in bringing the various churches of the Presbyterian order into closer touch with each other, and unwearying in his efforts to promote education for his countrymen.

EDWARDS, RICHARD (c. 1523-1566), English musician and playwright, was born in Somersetshire, became a scholar of Corpus Christi College, Oxford, in 1540, and took his M.A. degree in 1543. He was appointed to the chapel of Edward VI, the son and master of the children, and entered Lincoln's Inn in 1564, where at Christmas in that year he produced a play which was acted by his choir boys. On the 3rd of September 1566 his play, Palamon and Arcite, was performed before Queen Elizabeth in the Chapel of Christ Church, Oxford. Another play, Damon and Pithias, tragic in subject but with scenes of vulgar farce, entered at Stationers' Hall in 1567-8, appeared in 1571 and was reprinted in 1582; it may be found in Dodley's

EDWARDS, T. C.—EDWIN, JOHN

Old Plays, vol. i., and Ancient British Drama, vol. i. It is written in rhymed lines of rude construction, varying in length and neglect of the number of the author's shorter pieces are preserved in the Paradise of Dainty Devices, first published in 1575, and reprinted in the British Bibliographer, vol. iii.; the best known are the lines on May, the Amination Ioae, and the Commendation of Music, which has the honour of furnishing a stanza to Romeo and Juliet. The Historie of Damocles and Dionis is assigned to him in the 1578 edition of the Paradise. Sir John Hawkins credited him with the part song "In going to my lonely bed"; the words are certainly his, and probably the music. In his old age Edward was highly esteemed. The fine poem, "The Soul's Knell," is supposed to have been written by him when dying.

EDWARDS, THOMAS CHARLES (1837-1900), Welsh Non-conformist divine and educationist, was born at Bala, Merioneth, on the 2nd of September 1837, the son of Lewis Edwards (q.v.). His resolve to become a minister was deepened by the revival of 1858-1859. After taking his degrees at London (B.A. 1861, M.A. 1862), he matriculated at St Alban Hall, Oxford, in October 1862, the university having just been opened to dissenters. He obtained a scholarship at Lincoln College in 1864, and took a first class in the school of Literae Humaniores in 1866. He was especially influenced by Professor Pattison and Jowett, who counselled him to be true to the church of his father, in which he had already become an active member in 1862. In 1867 he became a fellow of Jesus College, St John's Street, Liverpool, but left it to become first principal of the University College of Wales at Aberystwyth, which had been established through the efforts of Sir Hugh Owen and other enthusiasts.

The college was opened with a staff of three professors and twenty-five students in October 1872, and for some years its career was chequered enough. Edwards, however, proved a skilful pilot, and his hold on the affection of the Welsh people enabled him to raise the college to a high level of efficiency. When it was destroyed by fire in 1883 he collected £25,000 to rebuild it; the remainder of the necessary £40,000 being given by the government (£10,000) and by the people of Aberystwyth (£5000). In 1891 he gave up what had been the main work of his life to accept an undertaking that was even nearer his heart, the principalship of the theological college at A banda. A stroke of paralysis in 1894 fatally weakened him, but he continued at work with his usual industry till the 2nd of March 1895. He was an active member of the Welsh Methodist Church of Wales, bestowed on him every honour in their possession, and he received the degree of D.D. from the universities of Edinburgh (1887) and Wales (1898). His chief works were a Commentary on 1 Corinthians (1885, the Epistles to the Hebrews ("Expositor's Bible" series, 1888), and The God-Man ("Davies Lectures," 1895).

EDWARDSVILLE, a city and a county-seat of Madison county, Illinois, U.S.A., in the south-western part of the state, on Cahokia Creek, about 18 m. N.E. of St Louis. Pop. (1890) 5561; (1900) 4157 (573 foreign-born); (1910) 5014. Edwardsville is served by the Toledo, St Louis & Western, the Wabash, the Litchfield & Madison, and the Illinois Terminal railways, and is connected with St Louis by three electric lines. It has a Carnegie library. The city's principal manufactures are carriages, ploughs, brick, machinery, sanitary ware and plumber's goods. Bituminous coal is extensively mined in the vicinity. Adjoining Edwardsville is the co-operative village Leclaire (unincorporated), with the factory of the N.O.Nelson Manufacturing Co., makers of plumber's supplies, brass goods, sanitary fixtures, &c.; the village was founded in 1890 by Nelson O. Nelson (b. 1844), and nearly all of the residents are employed by the company of which he is the head; they share to a certain extent in its profits, and are encouraged to own their own homes. The company supports a school, Leclaire Academy, and has built a club-house, bowling alleys, tennis courts, base-ball grounds, &c. The first settlement on the site of Edwardsville was made in 1812, and in 1815 the town was laid out and named in honour of Ninian Edwards (1775-1833), the governor of the Illinois Territory (1808-1818), and later United States senator (1838-1842) and governor of the state of Illinois (1826-1830). Edwardsville was incorporated in 1873.

EDWARDSVILLE, a borough of Luzerne county, Pennsylvania, U.S.A., on the north branch of the Susquehanna river, adjoining Kingston and close to the north-western limits of Wilkes-Barre (on the opposite side of the river), in the north-eastern part of the state; the official name of the post office is Edwardsdale. Pop. (1890), 3245; (1900), 5165, of whom 2645 were foreign-born; (1910 census), 8407. It is served by the electric line of the Wilkes-Barre & Wyoming Valley Traction Co. Coal mining and brewing are the chief industries. Edwardsville was incorporated in 1884.

EDWIN, AEDUNI or EDWINE (385-633), king of Northumbria, was the son of Ella of Deira. On the seizure of Deira by Æthelfrith of Bernicia (probably 605), Edwin was expelled and is said to have taken refuge with Cadfan, king of Gwynedd. After the battle of Chester, in which Æthelfrith defeated the Welsh, Edwin fled to Redwald, the powerful king of East Anglia, who after some wavering espoused his cause and defeated and slew Æthelfrith at the river Idle in 617. Edwin thereupon succeeded to the Northumbrian throne, driving out the sons of Æthelfrith. There is little evidence of external activity on the part of Edwin before 625. It is probable that the conquest of the Celtic kingdom of Elmet, a district in the neighbourhood of the modern Leeds, ruled over by a king named Ceridac (Ceredig) is to be referred to this period, and this may have led to the later quarrel with Cadfan, king of Gwynedd, when Edwin was supplanted by Cadfan. He married Æthelfrith's daughter Lindsey to his kingdom by 625. In this year he entered upon negotiations with Eadbald of Kent for a marriage with his sister Æthelberg. It was made a condition that Christianity should be tolerated in Northumbria, and accordingly Paulinus was consecrated bishop by Justus in 625, and was sent to Northumbria with Æthelberht. According to Bede, Edwin was favourably disposed towards Christianity owing to a vision he had seen at the court of Redwald, and in 626 he allowed Eanfrith, his daughter by Æthelberht, to be baptized. On the day of the birth of his daughter, the king's life had been attempted by Eomer, an emissary of Cwichelm, king of Wessex. Preserved by the devotion of his theng Lilla, Edwin vowed to become a Christian if victorious over his treacherous enemy. He was successful in the ensuing campaign, and abstained from the worship of the gods of his race. A letter of Pope Boniface helped to decide him, and after conquest of Eanfrith he was allowed to retain his kingdom. The battle of 627, in which the east Anglians and Northumbrians fought, proved a decisive victory.

To this battle succeeded a long period during which Edwin was at times exposed to danger from the Saxons. In 628 he was defeated by King Ecgberht, who put him to death, but was himself defeated and killed by Æthelred at the battle of Chadlington in 635. In 633 Cadwallon of North Wales and Penda of Mercia rose against Edwin and slew him at Hatfield near Doncaster. His kinsman Eorl succeeded in Deira, and Eanfrith the son of Æthelfrith in Bernicia. Bede tells us that Edwin had subdued the islands of Anglesey and Man, and the Annales Cambriae record that he besieged Cadwallon (perhaps in 632) in the island of Oganneu (Puffin Island). He was definitely recognized as overlord by all the other Anglo-Saxon kings of his day except Eadbald of Kent.

EDWIN, JOHN (1749-1790), English actor, was born in London on the 10th of August 1749, the son of a watchmaker. As a child he appeared in the provinces, in minor parts, and at Bath in 1758 he formed a connexion with a Mrs Walsmy, a milliner, who bore him a son, but whom he afterwards deserted. His first London appearance was at the Haymarket in 1776 as
Flaw in Samuel Foote's *The Cozeners*, but when George Colman took over the theatre he was given better parts and became its leading actor. In 1770 he was at Covent Garden, and played there or at the Haymarket until his death on the 31st of October 1790. Ascribed to him are *The Last Legacy of John Edwin*, 1780; *Edwin's Jest* and *Edwin's Pills to Purge Melancholy.*

His son, John Edwin (1768–1805), made a first appearance on the stage at the Haymarket as Hengo in Beaumont and Fletcher's *Bondoqua* in 1778, and from that time acted frequently with his father, and managed the private theatricals organized by his intimate friend Lord Barrington at Wargrave, Berks. In 1791 he married Elizabeth Rebecca Richards, an actress already well known in juvenile parts, and played at the Haymarket and elsewhere thereafter with her. He died in Dublin on the 22nd of February 1805. His widow joined the Drury Lane company (then playing, on account of the fire of 1809, at the Lyceum), and took all the leading characters in the comedies of the day. She died on the 3rd of August 1854.

**EDWY (EADWY)**, "**The Fair**" (c. 940–950), king of the English, was the eldest son of King Edmund and Elfgifu, and succeeded his uncle Eadred in 955, when he was little more than fifteen years old. He was crowned at Kingston by Archbishop Odo, and his troubles began at the coronation feast. He had retired to enjoy the company of the ladies Æðhelgifu (perhaps his foster-mother) and her daughter Ælfgifu, whom the king intended to marry. The nobles resented the king's withdrawal, and they took Ælfgifu, the well-beloved and most, of the Mercians and Cynesige, bishop of Lichfield, to return to the feast. Edwy naturally resented this interference, and in 957 Dunstan was driven into exile. By the year 956 Ælfgifu had become the king's wife, but in 958 Archbishop Odo of Canterbury secured their separation on the ground of their being too closely akin. Edwy, to judge from the disproportionately large numbers of charters issued during his reign, seems to have been weakly lavish in the granting of privileges, and soon the chief men of Mercia and Northumbria were disgusted by his partiality for Wessex. The result was that in the year 957 his brother, the Ætheling Edgar, was chosen as king by the Mercians and Northumbrians. It is probable that no actual conflict took place, and in 959, on Edwy's death, Edgar acceded peaceably to the combined kingdoms of Wessex, Mercia and Northumbria.

**ECKHOUT, GERBRAND VAN DEN** (1621–1674), Dutch painter, born at Amsterdam on the 10th of August 1621, entered early into the studio of Rembrandt. Though a companion pupil to F. Bol and Govaert Flinck, he was inferior to both in skill and in the extent of his practice; yet at an early period he assumed Rembrandt's manner with such success that his pictures were confounded with those of his master; and, even in modern days, the "Resurrection of the Daughter of Jairus," in the Berlin museum, and the "Presentation in the Temple," in the Dresden gallery, have been held to represent worthily the style of Rembrandt. As evidence of the fidelity of Eckhout's imitation we may cite his "Presentation in the Temple," at Berlin, which is executed after Rembrandt's print of 1630, and his "Tobit with the Angel," at Brunswick, which is composed on the same background as Rembrandt's "Philosopher in Thought." Eckhout not merely copies the subjects; he also takes the shapes, the figures, the Jewish dress and the pictorial effects of his master. It is difficult to form an exact judgment of Eckhout's qualities at the outset of his career. His earliest pieces are probably those in which he more faithfully reproduced Rembrandt's peculiarities. Exclusively his is a tinge of green in shadows marring the harmony of the work, a certain gauntness of jarring tints, uniform surface and a touch more quick than subtle. Besides the pictures already mentioned we should class amongst early productions on this account the "Woman taken in Adultery," at Amsterdam; "Anna presenting her Son to the High Priest," in the Louvre; the "Epiphany," at Turin; and the "Circumcision," at Cassel. Eckhout matriculated early in the Guild of Amsterdammers. A likeness of a lady at a dressing table with a string of beads, at Vienna, bears the date of 1643, and proves that the master at this time possessed more imitative skill than genuine mastery over nature. As he grew older he succeeded best in portraits, a very fair example of which is that of the historian Dappers (1669), in the Städel collection. Eckhout occasionally varied his style so as to recall in later years the "small masters" of the Dutch school. Waagen justly draws attention to his following of Terburg in *Gambling Soldiers,* at Stafford House, and a "Soldiers' Merrymaking," in the collection of the marquess of Bute. A "Sportsman with Hounds," probably executed in 1670, now in the Vander Hoo gallery, and a "Group of Children with Goats" (1671), in the Hermitage, hardly exhibit a trace of the artist's first education. Amongst the best of Eckhout's works is "Christ in the Temple" (1662), at Munich, and the "Haman and Mordecai" of 1665, at Luton House, occupy a good place. Eckhout died at Amsterdam on the 22nd of October 1674.

**EEL.** The common freshwater eel (*Anguilla vulgaris*; O. Eng. *eel*) belongs to a group of soft-rayed fishes distinguished by the presence of an opening to the air-bladder and the absence of the pelvic fins. With its nearest relatives it forms the family *Anguillidae*, all of which are of elongated cylindrical form. The peculiarities of the eel are the rudimentary scales buried in the skin, the well-developed opercular fins, the tail fin continuous with the dorsal and ventral fins. Only one other species of the family occurs in British waters, namely, the conger, which is usually much larger and lives in the sea. In the conger the eyes are larger than in the eel, and the upper jaw overlaps the lower, whereas in the eel the lower jaw projects beyond the upper. Both species are voracious and predatory, and feed on almost any animal food they can obtain, living or dead. The conger is especially fond of squids or other Cephalopods, while the eel greedily devours carrion. The common eel occurs in all the rivers and fresh waters of Europe, except those draining towards the Arctic Ocean, the Black Sea and the Caspian Sea. It also occurs on the Atlantic side of North America. The conger has a wider range, extending from the western and southern shores of Britain and Ireland to the East Indian Archipelago and Japan. It is common in the Mediterranean.

The ovaries of the eel resemble somewhat those of the salmon in structure, not forming closed sacs, as in the majority of Teleostei, but consisting of laminae exposed to the body cavity. The laminae in which the eggs are produced are very numerous, and are attached transversely by their inner edges to a membranous band running nearly the whole length of the body-cavity. The majority of the eels captured for market are females with the ovaries in an immature condition. The male eel was first discovered in 1873 by Synski at Trieste, the testis being described by him as a lobed elongated organ, in the same relative position as the ovary in the female, surrounded by a smooth surface without laminae. He did not find ripe spermatozoa. He discovered the male by examining small specimens, all the larger being female. L. Jacoby, a later observer, found no males exceeding 19 in. in length, while the female may reach a length of 39 in. or more. Dr C. G. J. Petersen, in a paper published in 1866, states that in Denmark two kinds of eels are distinguished by the fishermen, namely, yellow eels and silver eels. The silver eels are further distinguished by the shape of the snout and the size of the eyes. The snout in front of the eyes is not flat, as in the yellow eels, but high and compressed, and therefore appears more pointed, while the eyes are much larger and directed outwards. In both kinds there are males and females, but Petersen shows that the yellow eels change into silver eels when they migrate to the sea. The sexual organs in the river eels are more developed than in the yellow eels, and the former have almost or entirely ceased to take food. The male silver eels are from 11/2 to 19 in. in length, the females from 16 to about 39 in. It is evident, therefore, that if eels only spawn once, they do not all reach the same size when they become sexually mature. The male conger was first
described in 1879 by Hermes, who obtained a ripe specimen in the Berlin Aquarium. This specimen was not quite 2 ft. in length, and of the numerous males which have been identified at the Plymouth Laboratory, none exceeded this length. The large numbers of conger above this size caught for the market are all immature females. Female conger of 5 or 6 ft. in length and weighing from 30 to 50 lb. are common enough, and occasionally they exceed these limits. The largest recorded was 8 ft. 3 in. long, and weighed 128 lb.

There is every reason to believe that eels and conger spawn but once in their lives, and die soon after they have discharged their generative products. When kept in aquaria, both male and female conger are vigorous and voracious. The males sooner or later cease to feed, and attain to the sexually mature condition, emitting ripe milt when handled and gently squeezed. They live in this condition five or six months, taking no food and showing gradual wasting and disease of the bodily organs. The eyes and skin become ulcerated, the sight is entirely lost, and the bones become soft through loss of lime. The females also after a time cease to feed, and live in a fasting condition for five or six months, during which time the ovaries develop and reach great size and weight, while the bones become soft and the teeth disappear. The female, however, always dies in confinement before the ova are perfectly ripe and before they are liberated from the ovarian tissue. The absence of some necessary condition, perhaps merely of the pressure which exists at the bottom of the sea, evidently prevents the complete development of the ovary. The invariable death of the fish in the same almost ripe condition leads to the conclusion that under normal conditions the fish dies after the mature ova have been discharged. G. B. Grassi states that he obtained ripe male eels, and ripe specimens of Muraena, another genus of the family, in the whirlpools of the Strait of Messina. A ripe female Muraena has also been described at Zanzibar. Gravid female eels, i.e. specimens with ovaries greatly enlarged, have been occasionally obtained in fresh water, but there is no doubt that, normally, sexual maturity is attained only in the sea.

Until recent years nothing was known from direct observation concerning the reproduction of the common eel or any species of the family. It was a well-known fact that large eels migrated towards the sea in autumn, and that in the spring small transparent eels of 2 in. in length and upwards were common on the shore under stones, and ascended rivers and streams in vast swarms. It was reasonable, therefore, to infer that the mature eels spawned in the sea, and that there the young were developed. A group of peculiar small fishes were, however, known which were called Leptocephali, from the small proportional size of their body. The chief peculiarities of Leptocephali, in addition to the smallness of the head, are their ribbon-like shape and their glassy transparency during life. The body is flattened from side to side, and broad from the dorsal to the ventral edge. Like the eels, they are destitute of pelvic fins, and no generative organs have been observed in them (see fig.).

In 1864 the American Ichthyologist, T. N. Gill, published the conclusion that L. morrisii was the young or larva of the conger, and Leptocephali generally the young stages of species of Muraenidae. In 1886 this conclusion was confirmed from direct observation by Yves Delage, who kept alive in a tank at Roscoff a specimen of L. morrisii, and saw it gradually transformed into a young conger. From 1887 to 1892 Professor Grassi and Dr Calandruccio carried on careful and successful researches into the development of the Leptocephali at Catania, in Sicily. The specimens were captured in considerable numbers in the harbour, and the transformation of L. morrisii into young conger, and of various other forms of Leptocephalus into other genera of Muraenidae, such as Muraena, Congromuraena and Ophichthys, was observed.

In 1894 the same authors published the announcement that another species of Leptocephalus, namely, L. breviceps, was the larva of the common eel. This larval form was captured in numbers with other Leptocephali in the clear currents of the Strait of Messina. In the metamorphosis of all Leptocephali a great reduction in size occurs. The L. breviceps reaches a length of 8 cm., or a little more than 2½ in., while the perfectly-formed young eel is 2 in. long or a little more.

The Italian naturalists have also satisfied themselves that certain pelagic fish eggs originally described by Raffaele at Naples are the eggs of Muraenidae, and that among them are the eggs of Conger and Anguilla. They believe that these eggs, although free in the water, remain usually near the bottom at great depths, and that fertilization takes place under similar conditions. No fish eggs of the kind to which reference is here made have yet been obtained on the British coasts, although conger and eels are so abundant there. Raffaele described and figured the larva newly hatched from one of the eggs under consideration, and it is evident that this larva is the earliest stage of a Leptocephalus.

Although young eels, some of them more or less flat and transparent, are common enough on the coasts of Great Britain and north-western Europe in spring, neither eggs nor specimens of Leptocephalus breviceps have yet been taken in the North Sea, English Channel or other shallow waters in the neighbourhood of the British Islands, or in the Baltic. Marked eels have been proved to migrate from the inmost part of the Baltic to the Kattegat. Recently, however, search has been made for the larvae in the more distant and deeper portions of the Atlantic Ocean. In May 1904 a true larval specimen was taken at the surface south-west of the Faeroe Islands, and another was taken 40 m. north by west of Achill Head, Ireland. In 1905 numbers were taken in deep water in the Atlantic. The evidence at present available indicates that the spawning of mature eels takes place beyond the 100 fathom line, and that the young eels which reach the coasts are already a year old. As eels, both young and old, are able to live for a long time out of water and have the habit of travelling at night over land in wet grass and in damp weather, there is no difficulty in explaining their presence in wells, ponds or other isolated bodies of fresh water at any distance from the sea.

to the sultan. The possessive form effendim (my master) is used by servants and in formal intercourse.

EFFIGIES, MONUMENTAL. An "effigy" (Lat. effigies, from effigere, to fashion) is, in general, a material image or likeness of a person; and the practice of hanging or burning people "in effigy," i.e. their semblance only, preserves the more general sense of the word. Such representations may be portraits, carvings, or sculptures. But, as the most significant acceptance of that term, valuable contemporaneous portraits.

Once esteemed to be simply objects of antiquarian curiosity, and either altogether disregarded or too often subjected to injurious indignity, the monumental effigies in England long awaited the formation of a just estimate of their true character and their consequent worth in their capacity as authorities for facial and general types. But it was the original conception of the construction of the monument at Warwick to Richard Beauchamp, the fifth earl, who died in 1439, that it is provided that an effigy of the deceased noble should be executed in bronze gilt, with all possible care, by the most skilful and experienced artists of the time; and the details of the armour and the ornaments of the figure are specified with minute precision. It is remarkable, however, that the effigy itself is described only in the general and indefinite terms—"an image of a man armed." There is no provision that the effigy should be "an image" of the earl; and much less is anything said as to its being such a "counterfeit presentment" of the features and person of the living man, as the contemporaries of Shakespeare had learned to expect in what they would accept as true portraiture. The effigy, almost as perfect as when it left the sculptor's hands, still bears witness, as well to the conscientious care with which the conditions of the contract were fulfilled, as to the eminent ability of the artists employed. So complete is the representation of the armour, that this effigy might be considered actually to have been equipped in the earl's own favourite suit of the finest Milan steel. The cast of the figure also was evidently studied from what the earl had been when in life, and the countenance is sufficiently marked and endowed with the unmistakable attributes of personal character. Possibly such a resemblance may have been the highest aim in the image-making of the period, somewhat before the middle of the 15th century. Three-quarters of a century later, a decided step towards fidelity in true portraiture is shown to have been taken, when, in his will (1510 A.D.), Henry VII. spoke of the effigies of himself and of his late queen, Elizabeth of York, to be executed for their monument, as "an image of our figure and another of hers." The existing effigies in the Beauchamp chapel and in Henry VII.'s chapel, with the passages just quoted from the contract made by the executors of the Lancasterian earl, strikingly illustrate the gradual development of the idea of true personal portraiture in monumental effigies, during the course of the 15th and at the commencement of the 16th century in England.

Study of the royal effigies still preserved must commence in Worcester Cathedral with that of King John. This earliest example of a series of effigies of which the historical value has never yet been duly appreciated is rude as a work of art, and yet there is on it the impress of such individuality as demonstrates that the sculptor did his best to represent the king. Singularly fine as achievements of the sculptor's art are the effigies of Henry III., Queen Eleanor of Castile, and her ill-fated son Edward II., the two former in Westminster Abbey, the last in Gloucester cathedral; and of their fidelity also as portraits no doubt can be entertained. In like manner the effigies of Edward III. and his queen Philippa, and those of their grandson Edward I. and his first consort, Anne of Bohemia (all at Westminster), and of their other grandson, Henry of Lancaster, with his second consort, Joan of Navarre, at Canterbury—all convince us that they are true portraits. Next follow the effigies of Henry VII. and Elizabeth of York,—to be succeeded, and the royal series to be completed, by the effigies of Queen Elizabeth and Mary Stuart, all of them in Westminster Abbey. Very instructive would be a close comparison between the two last-mentioned series and the original personal representations of the royal queens, especially in the case of Mary, the pictures of whom differ so remarkably from one another.

As the 15th century advanced, the rank of the personage represented and the character of the art that distinguishes any effigy goes far to determine its portrait qualities. Still later, when more exact face-portraiture had become a recognized element, sculptors must be supposed to have aimed at the
production of such resemblance as their art would enable them to give to their works; and accordingly, when we compare effigies with painted portraits of the same personages, we find that they corroborate one another. The prevalence of portraits in the effigies of the 16th and 17th centuries—a matter the importance of which is inconsiderable for the purpose of busts and half-lengths towards the end of the 16th century, imported, of course, from abroad. Sometimes the stone monuments were painted to resemble life, as in the monuments to Shakespeare and John Combe (the latter now over-painted white), in Holy Trinity Church, Stratford-on-Avon.

BIBLIOGRAPHY.—Among the more noteworthy publications are the following: Monumental Effigies; the best as in the Church of Grafton (Conquest to Henry VIII.), by C. A. Stothard, folio (London, 1876); The Recumbent Monumental Effigies in Northamptonshire, by A. Harshorne (4to, London, 1867-1876); Sepulchral Memorials (Shropshire), by Mrs. Jolliffe (London, 1877); Armorial Sepulchral Effigies and Monumental Sculpture of Devon, by W. H. H. Rogers (4to, Exeter, 1877); The Ancient Sepulchral Monuments of Essex, ed. by C. M. Carton (4to, Chelmsford, 1890); and other works dealing with the subject according to counties. Of particular value is the Report of the Sepulchral Monuments Committee of the Society of Antiquaries, laboriously compiled at the request of the Office of Works (arranged (1) personally and topographically, and (2) locally (1872).

EGAN, PIERCE (1772-1840), English sporting writer, was born in London in 1772. He began life as sporting reporter for the newspaper, and was soon recognized as the best of his day. In 1814 he wrote, set and printed a book about the relations of the prince regent (afterwards George IV.) and Miss Robinson, called The Mistress of Royalty, or the Loves of Florinda and Percival. But his best-known work is Enumerations of Harry Hawthorne and his Elegant Friend Corinthian Tom (1821), a book describing the amusements of sporting men, with illustrations by Cruikshank. This book took the popular fancy and was one of Thackeray's early favourites (see his Roundabout Papers). It was repeatedly imitated, and several dramatic versions were produced in London. A sequel containing more of country sports and misadventures probably suggested Dickens's Pickwick Papers. In 1834 Pierce Egan's Life in London and Sporting Guide was started, a weekly newspaper afterwards incorporated with Bell's Life. Among his numerous other books are Botanica (1818), Life of an Actor (1824), Book of Sports (1832), and The Pilgrims of the Thames (1838). Egan died at Pentonville on the 3rd of August 1849.

His son, Pierce Egan (1814-1880), illustrated his own and his father's books, and wrote a score of novels of varying merit, of which The Snake in the Grass (1858) is perhaps the best known. He was a secret society flourishing chiefly among the Egots of the Calabar district, West Africa. Egbo or Ekpe is a mysterious spirit who lives in the jungle and is supposed to preside at the ceremonies of the society. Only males can join, boys being initiated about the age of puberty. Members are bound by oath of secrecy, and fees on entrance are payable. The Egbo-men are ranked in seven or nine grades, for promotion to each of which fresh initiation ceremonies, fees and oaths are necessary. The society combines a kind of freemasonry with political and law-enforcing aims. For instance any member wronged in an Egbo district, that is one dominated by the society, has only to address an Egbo-man or beat the Egbo drum in the Egbo-house, or "blow Egbo" as it is called, i.e. sound the Egbo horn before the hut of the wrong-doer, and the whole machinery of the society is put in force to see justice done. Formerly the society earned as bad a name as most secret sects, from the barbarous customs mingled with its rites; but the British authorities have been able to prevent the use of it in enforcing order and helping on civilization. The Egbo-house, an oblong building like the nave of a church, usually stands in the middle of the villages. The walls are of clay elaborately painted inside and ornamented with clay figures in relief. Inside are wooden images, sometimes of an obscene nature, to which reverence is paid. Much social importance attaches to the highest ranks of Egbo-men, and it is said that very large sums, sometimes more than a thousand pounds, are paid to attain these dignities. At certain festivals in the year the

Egebo-men wear black wooden masks with horns which it is death for any woman to look on. The Rev. Robt. H. Nasm, Fellow in West Africa (1901); Rev. Robt. H. Nasm, Fellow in West Africa (1904); C. Partridge, Cross River Native (1905).

EGEDE, Hans (1686-1758), Norwegian missionary, was born in the vothsip of Senjen, Norway, on the 31st of January 1786. He studied at the university of Copenhagen, and in 1706 became pastor at Vaagen in the Lofoten islands, but the study of the chronicles of the northerners having awakened in him the desire to visit the colony of Northerners in Greenland, and to convert them to Christianity, he resigned his charge in 1717; and having after great difficulty, obtained the sanction and help of the Danish government in his enterprise, he set sail with three ships from Bergen on the 3rd of May 1721, accompanied by his wife and children. He landed on the west coast of Greenland on the 3rd of July, but found to his dismay that the Northerners were entirely superseded by the Eskimo, in whom he had no particular interest, and whose language he would be able to master, if at all, only after years of study. But, though compelled to endure for some years great privations, and at one time to see the result of his labours almost annihilated by the ravages of small-pox, he remained resolutely at his post. He founded the colony of Godthaab, and soon gained the affection of the people. He converted many of them to Christianity, and established a considerable commerce with Denmark. Ill-health compelling him to return home in 1736, he was made principal of a seminary at Copenhagen, in which he was trained for the Greenland mission; and from 1740 to 1747 he was superintendent of the Greenland mission. He died on the 6th of November 1758. He is the author of a book on the natural history of Greenland.

His work in Greenland was continued, on his retirement, by his son Paul Egede (1708-1789), who afterwards returned to Denmark and succeeded his father as superintendent of the Greenland mission. Paul Egede also became professor of theology in the mission seminary. He published a Greenland-Danish-Latin dictionary (1750), Greenland grammar (1750) and Greenland catechism (1755). In 1766 he completed the translation begun by his father of the New Testament into the Greenland tongue; and in 1787 he translated Thomas à Kempis. In 1789 he published a journal of his life in Greenland.

EGER, Aquiba (1761-1837), Jewish scholar, was for the last twenty-five years of his life rabbi of Posen. He was a rigorous Touist of the old school, and his chief works were legal notes on the subject of the code of Qur of Qarn (q.v.). He believed that religious education was enough, and thus opposed the party which favoured secular schools. He was a determined foe of the reform movement, which began to make itself felt in his time.

EGER (Czech, Cheb), a town of Bohemia, Austria, 148 m. W.N.W. of Prague by rail. Pop. (1901) 23,665. It is situated on the river Eger, at the foot of one of the spurs of the Fichtelgebirge, and lies in the centre of a German district of about 40,000 inhabitants, who are distinguished from the surrounding population by their costumes, language, manners and customs. On the rock, to the N.W. of the town, lies the Burg or Castle, built probably in the 12th century, and now in ruins. It possesses a massive black tower, built of blocks of lava, and in the courtyard is an interesting chapel, in Romanesque style with fantastic ornamentations, which was finished in the 13th century. In the banquet-room of this castle Wallenstein's officers Tersky, Kinsky, Illo and Neumann were assassinated a few hours before Wallenstein himself was murdered by Captain Devereux. The murder took place on the 29th of February 1634 in the town-house, which was at that time the burgomaster's house. The rooms occupied by Wallenstein have been transformed since 1872 into a museum, which contains many historical relics and antiquities of the town of Eger. The handsome and imposing St Nicholas church was built in the 13th century and restored in 1692. There is a considerable textile industry, together with the manufacture of shoes, machinery and iron. Eger was the birthplace of the novelist and playwright Braun von Brauntal (1820-1860). About 3 m. N.W. of Eger is the well-known watering place of Fränzensbad (q.v.).

The district of Eger was in 870 included in the new margravate of Franconia, which was immediately, first to the Barvarians, and from 906 to the counts of Vohburg, who took the title of margraves of Eger. By the marriage, in 1140, of Adela of Vohburg with the emperor Frederick I., Eger came into the possession of the house of Swabia, and remained in the hands of the emperors until the 14th century. In 1265 it was taken by Ottakar II. of Bohemia, who retained it for eleven years. After being repeatedly transferred from the one power to the other, according to the precedence of Bohemia or the empire, the town and territory were finally incorporated with Bohemia in 1526, after the Bohemian king became the emperor Charles IV. Several imperial privileges, however, continued to be enjoyed by the town till 1849. It suffered severely during the Hussite war, during the Swedish invasion in 1631 and 1647, and in the War of the Austrian Succession in 1742.

EGERTON—EGG

there was also a Manius Ergierius, a male counterpart of Egeria. Her connexion with Dionysus, Nemorensis, herself a birth goddess, is confirmed by the fact that her biographer, Dion, always calls her the "female Dionysus," and that the women. She also possessed the gift of prophecy; and the statement (Dion. Halic. ii. 60) that she was one of the Muses is due to her connexion with the Camenae, whose worship was displaced by them.

EGERTON, SIR PHILIP DE MALPAS GREY, Bart. (1806–1881), English palaeontologist, was born on the 16th of November 1806, the son of the 9th baronet. He was educated at Eton and at Christ Church, Oxford, where he graduated, B.A., in 1828. While at college his interest in geology was aroused by the lectures of W. Buckland, and by his acquaintance with W. D. Conybeare. Subsequently when travelling in Switzerland with Lord Cole (afterwards 3rd earl of Enniskillen) they were introduced to Prof. L. Agassiz at Neuchatel, and determined to make a special study of fossil fishes. During the course of fifty years they gradually gathered together two of the largest and finest of private collections—that of Sir Philip Grey Egerton being at Oulton Park, Tarporley, Cheshire. He described the structure and affinities of numerous species in the publications of the Geological Society of London, the Geological Magazine and the Decades of the Geological Survey; and in recognition of his services the Wollaston medal was awarded to him in 1873 by the Geological Society. He was elected F.R.S. in 1831, and was a trustee of the British Museum. As a Member of Parliament he represented the city of Chester in 1850, the southern division of Cheshire in 1852 until 1868, and the western division from 1868 to 1881. He died in London on the 6th of April 1881. His collection of fossil fishes is now in the British Museum.

EGG, AUGUSTUS LEOPOLD (1816–1863), English painter, was born on the 2nd of May 1816 in London, where his father carried on business as a gun-maker. He had some schooling at Beasley, and was not at first intended for the artistic profession; but, developing a faculty in this line, he entered in 1834 the drawing class of Mr Sass, and in 1836 the school of the Royal Academy. His first exhibited picture appeared in 1837 at the Suffolk Street gallery. In 1838 he began exhibiting in the Academy, his subject being a "Spanish Girl"; altogether he sent twenty-seven works to this institution. In 1848 he became an associate and in 1860 a full member of the Academy: he had considerable means, apart from his profession. In 1857 he took a leading part in selecting and arranging the modern paintings in the Art-Teach exhibition in Manchester; and, as of his constitution being naturally frail, he went in 1853, with Dickens and Wilkie Collins, to Italy for a short trip, and in 1863 he visited Algeria. Here he benefited so far as his chronic lung disease was concerned; but exposure to a cold wind while out riding brought on an attack of asthma, from which he died on the 26th of March 1863 at Algiers, near which city his remains were buried.

Egg was a gifted and well-trained painter of genre, chiefly in the way of historical anecdote, or of compositions from the poets and novelists. Among his principal pictures may be named: 1843, the "Introduction of Sir Fiercic Shafton and Halbert Glendinning" (from Scott's Monastery); 1846, "Buckingham Rebuffed"; 1848, "Queen Elizabeth discovers she is no longer young"; 1850, "Peter the Great sees Catharine for the first time"; 1854, "Charles I raising the Standard at Nottingham" (a study); 1855, the "Life and Death of Buckingham"; 1857 and 1858, two subjects from Thackeray's Esmond; 1857, the "Past and Present, a trip to the circus of a faithless wife"; 1859, the "Night before Naseby"; 1860, his last exhibited work, the Dinner Scene from The Taming of the Shrew. The Tate Gallery contains one of his earlier pictures, Patricio entertaining two Ladiess, from the Double boises; it was painted in 1844.

Egg was rather below the middle height, with dark hair and a handsome well-formed face; the head of Peter the Great (in the picture of Peter and Catharine, which may be regarded as his best work, which he made and was employed by Sir George Beaumont) is study, but of course considerably modified, from his own countenance. He was manly, kind-hearted, pleasant, and very genial and serviceable among brother-artists; social and companionable, but holding mainly aloof from fashionable circles. As an actor he had uncommon talent. He appeared among Dickens's company of amateurs in 1852 in Lord Lytton's comedy Not so Bad as we Seem, and afterwards in Wilkie Collins's Frozen Deep, playing the humorous part of Job Want.

EGG (O.E. egg, cf. Ger. Ei, Swed. egg, and prob. Gr. ἐος, Lat. uova), the female reproductive cell or ovum of animals, which gives rise generally only to the young. The largest eggs are those of birds; and this because, to the minute essential portion of the egg, or germ, from which the young bird is developed, there is added a large store of food-material in the yolk and white of the egg—destined to nourish the growing embryo while the whole is enclosed within a hard shell.

The relative sizes of eggs depend entirely on the amount of the food-yolk thus enclosed with the germ; while the form and texture of the outer envelope are determined by the nature of the environment to which the egg is exposed. Where the food material is infinitesimal in quantity the egg is either not extruded—the embryo being nourished by the maternal tissues,—or it passes out of the maternal body and gives rise to at once to a free-living organism or "larva" (see Larval Forms), as in the case of many lowly freshwater and marine animals. In such cases no "egg" in the usual sense of the term is produced.

The number of eggs periodically produced by any given individual depends on the risks of destruction to which they, and the young to which they give rise, are exposed: not more than a single egg being annually laid by some species, while with others the number may amount to millions.

Birds' Eggs.—The egg of the bird affords, for general purposes, the readiest example of the modifications imposed on eggs by the external environment. Since it must be incubated by the warmth of the parent's body, the outer envelope has taken the form of a hard shell for the protection of the growing chick from pressure, while the dyes which commonly colour the surface of this shell serve as a screen to hide it from egg-eating animals.

Carbonate of lime forms the principal constituent of this shell; but in addition phosphate of lime and magnesia are also present. In section, this shell will be found to be made up of three or less distinct crystalline layers, traversed by vertical canals, whereby the shell is made porous so as to admit air to the developing chick. The outermost, or third, layer of this shell often takes the form of a glass of calcareous, as for example in the barnacle, the ostrich: or it may assume the character of a thick, chitinous layer as in some cuccoos (Grauia, Crotaphaga amar), cormorants, grebes and flamingoes: while in some birds as in the auks, gulls and timanous, this outer layer is wanting; yet the tinamous have the most highly glazed eggs of all birds, the second layer of the shell developing a surface even more perfectly burnished than that formed by the outermost, third layer in the ostrich.

While the eggs of some birds have the shell so thin as to be translucent, e.g. kingfisher, others display considerable thickness, the maximum being reached in the egg of the extinct Aptornis.

Though in shape differing but little from that of the familiar hen's egg, certain well-marked modifications of form are yet to be met with. Thus the eggs of the plover are pear-shaped, of the sand-grouse more or less cylindrical, of the owls and titmice spherical and of the grebes biconical.

In the matter of coloration the eggs of birds present a remarkable range. The pigments to which this coloration is due have been shown, by means of their absorption spectra (Sorby, Proc. Zool. Soc., 1875), to be seven in number. The first of these, oorhodeine, is brown-red in tone, and rarely absent: the second and third, ocyanin, and banded ocyanin, are of a beautiful blue, and though differing spectroscopically give rise to the same product when oxidized: the fourth and fifth are yellow, and rufous oxanthine, the former combining with ocyanin gives rise to the beautiful dark malachite green of the emu egg, while the latter occurs only in the eggs of tinamous: the sixth is lichenoxanthine, a pigment not yet thoroughly known but present in the shells of all eggs having a peculiar brick-red colour. Still less is known of
the seventh pigment which is, as yet, nameless. It is a substance giving a banded absorption spectrum, and which, mixed with other pigments, imparts an abnormally browner tint. The origin of these pigments is yet uncertain, but it is probable that they are derived from the haemoglobin or red colouring matter of the blood. This being so, then the pigments of the egg-shell differ entirely in their nature from those which colour the yolk or the feathers.

While many eggs are either colourless or of one uniform tint, the majority have the surface broken up by spots or lines, or a combination of both, of varying tints: the pigment being deposited as the egg passes down the lower portion of the oviduct. That the egg during this passage turns slowly on its long axis is shown by the fact that the spots and lines have commonly a spiral direction; though some of the markings are made during periods of rest, as is shown by their sharp outlines, movement giving a blurred effect. Where the egg is pyriform, the large end makes way for the smaller. Many eggs display, in addition to the strongly marked spots, more or fewer fainter spots embedded in a deeper layer of the shell, and hence such eggs are said to be “double-spotted,” *e.g.* rails and plovers.

Among some species, as in birds of prey, the intensity of this coloration is said to increase with age up to a certain point, when it as gradually decreases. Frequently, especially where but two eggs are laid (Newton), all the dye will be deposited, sometimes on the first instantly exposed on the last laid, leaving the other colourless.

But although of a number of eggs in a “clutch” as the full complement of eggs in a nest is called—no two are exactly alike, they commonly bear a very close resemblance. Among certain species, however, which lay several eggs, one of the number invariably differs markedly from the rest, as for example in the eggs of the house-sparrow or in those of the sparrow-hawk, where, of a clutch of six, two generally differ conspicuously from the rest. Differing though these eggs do from the rest of the clutch, all yet present the characters common to the species. But the eggs of some birds, such as the Australian swamp quail, *Synoicus australis*, present a remarkably wide range of variation in the matter of coloration, no two clutches being alike, the extremes ranging from pure white to eggs having a greenish ground colour and rufous spots or blotches. But a still more interesting illustration of variation equally marked is furnished by the chikor partridge (*Cacocia chukor*), since here the variation appears to be correlated with the character of ground distribution of the species. Thus eggs taken in Greece are for the most part cream-coloured and unpigmented; those from the Grecian Archipelago are generally spotted and blotched; while more to the eastward spots are invariably present, and the blotches attain their maximum development.

But in variability the eggs of the guillemot (*Lomvia troile*) exceed all others: both in the hue of the ground colour and in the form of the superimposed markings, these eggs exhibit a wonderful range for which no adequate explanation has yet been given.

Individual peculiarities of coloration are commonly reproduced, not only with this species but also in others, year after year.

The coloration of the egg bears no sort of relation to the coloration of the bird which lays it; but it bears on the other hand a more or less direct relation to the nature of the environment during incubation.

White eggs may generally be regarded as representing the primitive type of egg, since they agree in this particular with the eggs of reptiles. And it will generally be found that eggs of this hue are deposited in holes or in domed nests. So long indeed as nesting-places of this kind are used will the eggs be white. And this because coloured eggs would be invisible in dimly lighted chambers of this description, and those constantly exposed to the risk of being broken by the sitting bird, or rolling out of reach where the chamber was large enough to admit of this, whereas white eggs are visible so long as they can be reached by the faintest rays of light. Pigeons invariably lay white eggs; and while some deposit them in holes others build an open nest, a mere platform of sticks. These exceptions to the rule show that the depredations of egg-eating animals are sufficiently guarded against by the overhanging foliage, as well as by the great distance from the ground at which the nest is built. Birds which have reverted to the more ancient custom of nesting in holes after having developed pigmented eggs, have adopted the device of covering the shell with a layer of chalky matter (e.g. puffins), or, to put the case more correctly, they have been enabled to maintain survival after their return to the more ancient mode of nidification, because this reversion was accompanied by the tendency to cover the pigmented surface of the shell with this light-reflecting chalky incrustation.

Eggs which are deposited on the bare ground, or in other exposed situations, are usually protectively coloured: that is to say, the hue of the shell more or less completely harmonizes with the ground on which the egg is placed. The eggs of the plower tribe afford the most striking examples of this fact.

But the majority of birds deposit their eggs in a more or less elaborately constructed nest, and in such cases the egg, so far from being protectively coloured, often displays tints that would appear calculated rather to attract the attention of egg-stealing animals; bright blue or blue spotted with black being commonly met with. It may be, however, that coloration of this kind is less conspicuous than is generally supposed, but in any case the safety of the eggs depends not so much on its coloration as on the character of the nest, which, where protective devices are necessary, must harmonize sufficiently with its surroundings to escape observation from prowling egg-stealers of all kinds.

The size of the egg depends partly on the number produced and partly on the conditions determining the state of the young bird at hatching: hence there is a great disparity in the relative sizes of the eggs of different birds. Thus it will be found that young birds which emerge in the world blind, naked and helpless are the product of relatively small eggs, while the contrary young hatched from relatively large eggs are down-clad and active from birth.

The fact that the eggs must be brooded by the parent is also a controlling factor in so far as number is concerned, for no more can be hatched than can be covered by the sitting bird. Other factors, however, less understood, also exercise a controlling influence in this matter. Thus the ostrich lays from 12 to 16, the teal 15, the partridge 12-20, while among many other species the number is strictly limited, as in the case of the hornbills and guillemots, which lay but a single egg; the apteryx, divers, pelicans and pigeons never lay more than 2, while the gulls and plovers never exceed 4. Tropical species are said to lay fewer eggs than their representatives in temperate regions, and further immature birds lay more and smaller eggs than when fully adult.

Partly owing to the uniformity of shape, size and texture of the shell, the eggs of birds are by no means easy to distinguish, especially in so far as their family resemblances are concerned: that is to say, except in particular cases, they cannot be specifically distinguished, and hence they are of but little or no value for the purposes of classification.

Save only among the megapodes, all birds brood their eggs, the period of incubation varying from 13 days, as in small passerine birds, to 8 weeks, as in the cassowary, though eggs of the rhea and of *Struthio* may hatch in from 5 to 6 weeks. But the megapodes deposit their eggs in mounds of decaying vegetable matter or in sand in the neighbourhood of hot springs, and there without further apparent care leave them. Where the nestling is active from the moment of hatching the eggs have a relatively longer incubation period than in cases where the nestlings are for a long while helpless.

**Eggs of Mammals.**—Only in the spiny ant-eater, or *Echidna*, and the duck-billed platypus, or *Ornithorynchus*, among the Mammalia, are the eggs provided with a large shell of yolk, enclosed within a shell, and extruded to undergo development apart from the maternal tissues. In the case of the echidna the eggs, two in number, are about as large as those of a sparrow,
similar in shape, and have a white, parchment-like shell. After expulsion they are transferred by the beak of the mother to a pouch resembling that of the marsupial kangaroos, and there they undergo development. The Ornithorhynchus, on the other hand, lays two to four eggs, which in size and general appearance resemble those of the echidna. They are, however, deposited in a loosely constructed nest at the end of a long burrow and there brooded. In Marsupials, the eggs are smaller than those of Echidna and Ornithorhynchus, and they contain a larger proportion of yolk than occurs in higher mammals.

**Eggs of Reptiles.**—The eggs of reptiles are invariably provided with a large amount of food yolk and enclosed with a firm test or shell, which though generally parchment-like in texture may be calcareous as in birds, as, for example, in many of the tortoises and turtles and in the crocodiles.

Among reptiles the egg is always white or yellowish, while the number laid often far exceeds that in the case of birds. The tuatara of New Zealand, however, lays but ten—white hard-shelled, long and oval—at intervals between November and January. The long intervals between the appearance of the successive eggs is a characteristic feature of the reptiles, but is met with among the birds only in the megapodes, which, like the reptiles, do not "brood" their eggs.

Among the Chelonia the number of eggs varies from two to four in some of the tortoises, to 300 in some of the turtles; while in the crocodiles between 20 and 30 are produced, hard-shelled and white.

The eggs of the lizards are always white or yellowish, and generally soft-shelled; but the geckos and the green lizard lay hard-shelled eggs. Many of the soft-shelled eggs are remarkable for the fact that they increase in size after extrusion, owing to the stretching of the membranous shell by the growing embryo. In the matter of number lizards are less prolific than many of the Chelonia, a dozen eggs being the general number, though as many as thirty may be produced at a time, as in the case of the common chameleon.

While as a general rule the eggs of lizards are laid in burrows or buried, some are retained within the body of the parent until the young are ready to emerge; or they may even hatch within the oviduct. This occurs with some chameleons and some lizards, e.g. the slow-worm. The common English lizard is also viviparous. When the eggs are laid in the nest they may be immediately after its extrusion, but if by any chance this extrusion is delayed they escape while yet in the oviduct.

The majority of the snakes lay eggs, but most of the vipers and the aquatic snakes are viviparous, as also are a few terrestrial species. The shell of the egg is always soft and parchment-like. As a rule the number of eggs produced among the snakes is not large, twenty or thirty being common, but some species of python lay as many as a hundred. Generally, among the oviparous snakes the eggs are buried, but some species of boa jealously guard them, enclosing them within the coils of the body.

**Eggs of Amphibia.**—Among the amphibia a greater variety obtains in the matter of the investment of the egg, as well as in the number, size and method of their disposal. Viviparous covering is formed by a toughening of the surface of a thick gelatious coat which surrounds the essential parts of the egg. This coat in many species of salamander—using this name in the wide sense—produces into threads which serve either to anchor the eggs singly or to bind them together in bunches.

Viviparity occurs both among the limbless and the tailed Amphibia, the eggs hatching before they leave the oviduct or immediately after extrusion. The number of young so produced is generally not large, but the common salamander (Salamandra maculata) may produce as many as fifty at a birth, though fifteen is the more normal figure. When the higher number is reached the young are relatively small and weak.

As a rule among the Amphibia the young leave the egg in the form of larvae, generally known as "tadpoles"; but many species produce eggs containing a sufficient amount of food material to enable the whole of the larval phase to be completed before hatching.

Among the tailless Amphibia (frogs and toads) there are wide differences in the number of eggs produced, while the methods by which these eggs are disposed of present a marvellous variety.

As a rule vast quantities of eggs are shed by the female into the water in the form of "spawn." In the common toad as many as 7000 eggs may be extruded at a time. These leave the body in the form of two long strings—one from each oviduct—of translucent globules, gelatinous in texture, and enclosing a central sphere of yolk, the upper pole of which is black. The spawn of the common frog differs from that of the toad in that the eggs all adhere to form a huge jelly-like mass. But in many species the number of eggs produced are few; and these may be sufficiently stored with food-yolk to allow of the tadpole stage being passed before hatching, as in frogs of the genus *Hylodes*. In many cases the eggs are deposited out of the water and often in quite remarkable ways.

**Eggs of Fishes.**—The eggs of fishes present an extremely wide range of form, and a no less extensive range in the matter of number. Both among the cartilaginous and bony fishes viviparity occurs. Most of the sharks and rays are viviparous, but in a few of these species the eggs present some interesting and peculiar forms. Large in size, the outer coat or "shell" is in all cases born-like and flexible, but differs greatly in shape. Thus in the egg of the larger spotted dog-fish it is oblong in shape, flattened from side to side, and has the angles produced into long slender tendrils. As the egg is laid the lower tendrils project from the vent, and the mother rubs herself against some fixed body. The tendrils soon catch fast in some slight projection, when the egg is dragged forth there to remain till hatching takes place. A couple of narrow slits at each corner of the upper end serve to admit fresh water to the imprisoned embryo during the later stages of development; when development is complete escape is made through the end of the shell. In the rays or "skates," long spines take the place of tendrils, the egg simply resting at the bottom of the sea. The empty egg-cases of the rays are often found on the seashore, and are known as "Mermaids' purses." The egg of the Port Jackson shark (Cestracion) is of enormous size, pear-shaped, and provided with a spiral flange extending along the whole length of the capsule. In the *Chimaera* the egg is long, more or less spindle-shaped, and produced on each side into a broad flange having a fringed edge, so that the whole bears a close resemblance to a long leaf, broad and notched at one end, pointed at the other. This likeness to the seaweed among which it rests is doubtless a protective device, akin to that of the commonly coloured "birds' eggs." Among the often large and beautiful shells of many species of bony fishes the eggs generally take the form of small spheres, enclosed within a tough membrane or capsule. But they present many important differences, being in some fishes heavy and remaining at the bottom of the water, in other light and floating on the surface. While in some species they are distributed separately, in others they adhere together in masses. The eggs of the salmon, for example, are heavy, hard and smooth, and deposited separately in a trough dug by the parent and afterwards covered to prevent them from being carried away by the stream. In the perch they are adhesive and form long band-like masses of spawn adhering to water-plants. In the gobies the egg is spindle-shaped, and attached by one end by means of a network of fibres, resembling rootlets; while in the smelt the egg is loosely suspended by a membrane formed by the peeling off of a part of the outer sheath of the capsule. The eggs of the garfish (Belone vulgaris) and of the flying-fish of the genus Eustrotius, attach themselves to foreign objects, or to one another, by means of threads or cords developed at opposite poles of the egg.

Among a number of fishes the eggs float at the surface of the sea, often in enormous masses, when they are carried about at the mercy of tides and currents. An idea of the size which such
masses attain may be gathered from the fact that the spawn of the angler-fish, *Lophius piscatorius*, takes the form of a sheet from 2 to 3 ft. wide, and 30 ft. long. Another remarkable feature of these floating eggs is their transparency, inasmuch as they are extremely difficult to see, and hence they probably escape the rapacious maws of spawn-eating animals. The cod tribe and flat-fishes lay floating eggs of this description.

The maximum number of eggs laid by fishes varies greatly, some species laying relatively few, but others an enormous number. But in all cases the number increases with the weight and age of the fish. Thus it has been calculated that the number laid by the salmon is roughly about 1000 to every pound weight of the fish, a 15 lb salmon laying 15,000 eggs. The sturgeon lays about 7,000,000; the herring 50,000; the turbot 14,311,000; the sole 134,000; the perch 280,000. Briefly, the number is greatest where the risks of destruction are greatest.

The eggs of the degenerate fishes known as the lampreys and hag-fishes are remarkable for the fact that in the latter they are large in size, cylindrical in shape, and provided at each end with hooklets whereby they adhere one to another; while in the lampreys they are extremely small and embedded in a jelly.

*Mollusca.*—Among the Mollusca, Crustacea and Insects yolk-stored eggs of very remarkable forms are commonly produced. In variety, in this connexion, the Mollusca must perhaps be given the first place. This diversity, indeed, is strikingly illustrated by the eggs of the Cephalopoda. In the squid (*Loligo*), for example, the eggs are enclosed in long cylindrical cases, of which there are several hundreds, attached by one end to a common centre; the whole series looking strangely like a rough mop-head. Each case, in such a cluster, contains about 250 eggs, or about 40,000 in all. By way of contrast the eggs of the true cuttle-fish (*Sepia*) are deposited separately, each enclosed in a tough brown, pear-shaped capsule which is fastened by a stalk to a frond of sea-weed or other object. They appear to be extruded at short intervals, till the full complement is laid, the whole forming a cluster looking like a bunch of grapes. The octopus differs yet again in this matter, its eggs being very small, berry-like, and attached to a stalk which runs through the centre of the mass.

The eggs of the univalve *Mollusca* are hardly less varied in the shapes they take. In the common British *Purpura lividula* they resemble delicate pink grains of rice set on stalks; in *Busycan* they are disk-shaped, and attached to a band nearly 3 ft. long. The eggs of the shell-bearing slugs (Testacella) are large, and have the outer coat so elastic that if dropped on a stone floor they will rebound several inches; while some of the snails (*Bulinus*) lay eggs having a white calcareous and slightly iridescent shell, in size and shape closely resembling the egg of the pigeon. Some are even larger than the egg of the wood-pigeon. The beautiful violet-small (*Janthis*)—a marine species—carries its eggs on the under side of a gelatinous raft. No less remarkable are the eggs of the whelk; since, like those of the squids, they are not laid separately but enclosed in capsules, and these to the number of many hundreds form the large, ball-like masses so commonly met with on the seashore. When the eggs in these capsules hatch, the crowd of embryos proceed to establish an intermiconic warfare, devouring one another till only the strongest survives.

With the Mollusca, as with other groups of animals, where the eggs are exposed to great risks they are small, produced in great numbers, and give rise to larvae. This is well illustrated by the common oyster which annually dispenses about 50,000,000 eggs. But where the risk of destruction is slight, the eggs are large and produce young differing from the parent only in size, as in the case of the pigeon-like eggs of *Bulinus*.

*Crustacea.*—Among the higher Crustacea, as a rule, the eggs are carried by the female, attached to special appendages on the under side of the body. But in some—Squillas—they are deposed in burrows. Generally they are relatively small so that the young which emerge therefrom differ markedly in appearance from the parents, but in deep-sea and freshwater species the eggs are large, when the young, on emerging, differ but little from the adults in appearance.

*Insects.*—The eggs of insects though minute, are also remarkable for the great variety of form which they present, while they are frequently objects of great beauty owing to the sculptured markings of the shell. They are generally laid in clusters, either on the ground, on the leaves of plants, or in the water. Some of the gnats (*Culex*) lay them on the water. Cylindrical in shape they are packed closely together, set on end, the whole mass forming a kind of floating raft. Frequently, as in the case of the stick and leaf insect, the eggs are enclosed in capsules of very elaborate shapes and highly ornamented.

As to the rest of the Invertebrata—above the Protozoa the eggs are laid in water, or in damp places. In the former case they are as a rule small, and give rise to larvae; while eggs hatched on land are sometimes enclosed in capsules, "cocoons," as in the case of the earthworm, where this capsule is filled with a milky white fluid, of a highly nutritious character, on which the embryos feed.

Among some invertebrates two different kinds of eggs are laid by the same individual. The water-flea, *Daphnia* (a crustacean), lays two kinds of eggs known as "winter" and "summer" eggs. The summer eggs are carried by the female in a "brood-pouch" on the back. The "winter" eggs, produced at the approach of winter, differ markedly in appearance from the summer eggs, being larger, darker in colour, thicker shelled, and enclosed in a capsule formed from the shell or carapace, of the parent's body. "Winter eggs," however, may be produced in the height of summer. While the "summer eggs" are unfertilized, the winter eggs are fertilized by the sperm from the remarkable power of lying dormant for months or even years before they develop. The production of these two kinds of eggs is a device to overcome the cold of winter, or the drying up of the pools in which the species lives, during the heat of the summer. The power of resistance which such eggs possess may be seen in the fact that a sample of mud which had been kept dry for ten years still contained living eggs. In deep water where neither drought nor winter cold can seriously affect the *Daphnia*, they propagate all the year round by unfertilized "summer" eggs.

**EGGENBERG, HANS ULRICH VON,** PRINCE (1568–1634), Austrian statesman, was a son of Siegfried von Eggenberg (d. 1594), and began life as a soldier in the Spanish service, becoming about 1596 a trusted servant of the archduke of Styria, afterwards the emperor Ferdinand II. Having become a Roman Catholic, he was soon the chancellor and chief adviser of Ferdinand II. whose election as emperor he helped to secure. He directed the imperial policy during the earlier part of the Thirty Years' War, and was in general a friend and supporter of Wallenstein, and an opponent of Maximilian I., duke of Bavaria, and of Spain. He was largely responsible for Wallenstein's return to the imperial service early in 1632, and retired from public life just after the general's murder in February 1634, dying
at Laibach, on the 18th of October 1634. Egggenberg's influence with Ferdinand was so marked that it was commonly said that Austria rested upon three hills (Bergo: Egggenberg, Questenberg and Nellenberg). For his services to the emperor. Having received many valuable estates in Bohemia, and elsewhere, he was made a prince of the Empire in 1633, and duke of Krumau in 1625.

EGGER, ÉMILE (1813–1885), French scholar, was born in Paris on the 18th of July 1813. From 1840 till 1855 he was assistant professor, and from 1855 till his death professor of Greek literature in the Faculté des Lettres at Paris University. In 1854 he was elected a member of the Académie des Inscriptions and in 1875 of the Conseil supérieur de l'instruction publique. He was a voluminous writer, a sound and discursive scholar, and his influence was largely responsible for the revival of the study of classical philology in France. His most important works were Essai sur l'histoire de la critique chez les Grecs (1849), Notions élémentaires de grammaire comparée (1852), Aapolionis Dyssopo, essai sur l'histoire des théories grammaticales dans l'antiquité (1854), Mémoires de littérature ancienne (1862), Mémoires d'histoire ancienne et de philologie (1863), Les Pyrénées grecs du Musée du Louvre et de la Bibliothèque Impériale (1865), Études sur les traits publics chez les Grecs et les Romains (1866), L'Éclectisme en France (1866), La Littérature grecque (1860). He was also the author of Observations et réflexions sur le développement de l'intelligence et du langage chez les enfants (1879). Eggge died in Paris on the 1st of September 1885.

EGGLETON, EDWARD (1837–1900), American novelist and historian, was born in Vevay, Indiana, on the 10th of December 1837, of Virginia stock. Delicate health, by which he was more or less handicapped throughout his life, prevented his going to college, but he was naturally a diligent student. He was a Methodist circuit rider and pastor in Indiana and Minnesota (1857–1866); associate editor (1866–1867) of The Little Corporal, Chicago; editor of The National Sunday School Teacher, Chicago (1867–1870); literary editor and later editor-in-chief of The Independent, New York (1870–1871); and editor of Heath and Home in 1871–1872. He was pastor of the church of Christian Endeavour, Brooklyn, in 1874–1879. From 1880 until his death on the 2nd of September 1903, at his home on Lake George, New York, he devoted himself to literary work. His fiction includes Mr. Blake's Walking Stick (1860), for children, The Hoosier Schoolmaster (1863); The Mystery of Metropolis (1873); The Circuit Rider (1874); Rosy (1878); The Hoosier Schoolboy (1883); The Book of Queen Stories (1884), for children, The Graysons (1888), an excellent novel; The Faith Doctor (1891); and Duffels (1893), short stories. Most of his stories portrayed the pioneer manners and dialect of the Central West, and the Hoosier Schoolmaster was one of the first examples of American local realistic fiction; it was very popular, and was translated into French, German and Danish.

During the last third of his life Eggleson laboured on a History of Life in the United States, but he lived to finish only two volumes—The Beginers of a Nation (1896) and The Transit of Civilization (1900). In addition he wrote several popular compendiums of American history for schools and homes.

His brother George Cary Eggleson (1839– ), American journalist and author, served in the Confederate army; was managing editor and later editor-in-chief of Heath and Home (1871–1874); was literary editor of the New York Evening Post (1875–1881), literary editor and afterwards editor-in-chief of the New York Commercial Advertiser (1884–1889), and editorial writer for The World (New York) from 1889 to 1900. Most of his books are stories for boys; others, and his best, are romances dealing with life in the South especially in the Virginias and the Carolinas—before and during the Civil War. Among his publications may be mentioned: A Rebel's Recollections (1874), The Last of the Flatboats (1900); Camp Venture (1900); A Carolina Cavalier (1901); Dorothy South (1902); The Master of Warlock (1903); Evelyn Byrd (1904); A Daughter of the South (1905); Blind All Valley, and over Windsor Great Park to the Wind. On the hill was the Royal Indian Civil Engineering College, commonly called Cooper's Hill College, of which Sir George Tomkyns Chesney was the originator and first president (1871). It educated men for the public works, accounts, railways and telegraph departments of India, and included a school of forestry; but it was decided, in the face of some opposition, to close it in 1906, on the theory that it was unnecessary for a college with such a specialized object to be maintained by the government, in view of the readiness with which servants for these departments could be recruited elsewhere. Part of the organization, including the school of forestry, was transferred to Oxford University. Cooper's Hill gives name to a famous poem of Sir John Denham (1642). A large and handsome building houses the Royal Holloway College for Women (1886), founded by Thomas Holloway; in the neighbourhood is the sanatorium of the same founder (1889) for the treatment of mental ailments, accommodating 525 patients. The college for women, surrounded by extensive grounds, commands a wide view from the wooded slope on which it stands. The recreation hall, with its fine art collection, is the most notable room in this handsome building, which can receive 250 students. Within the parish, bordering the river, is the field of Runnymede, which, with Magna Carta Island lying off it, is famous in connexion with the signature of the charter by King John. Virginia Water, a large and picturesque artificial lake to the south of Windsor Great Park, is much frequented by visitors. It was formed under the direction of the duke of Cumberland, about 1750, and was the work of the brothers Thomas and Paul Sandby.

EGIN (Armenian Ags, "the spring"), an important town in the Mamuret el-Aziz vilayet of Asiatic Turkey (altitude 3300 ft.). Pop. about 20,000, fairly equally divided between Armenian Christians and Moslems. It is picturesquely situated in a theatre of knobby, abrupt rocks, on the right bank of the western Euphrates, which is crossed by a wooden bridge. The stone houses stand in terraced gardens and orchards, and the streets are mere rock ladders. Egin was settled by Armenians who emigrated from Van in the 11th century with Senechmer. On the 8th of November 1895 and in the summer of 1896 many Armenians were massacred here. (D. G. H.)

EGINTINE (E. Frisian, egisliets; Fr. agislier), a plant-name of which Dr R. C. A. Prior (Popular Names of British Plants, p. 70) says that it "has been the subject of much discussion, both as to its exact meaning and as to the shrub to which it properly belongs." The egisline of the herbalists was the sweet-brier, Rosa ruginosa. The signification of the word seems to be thorn-tree or thorn-bush, the first two syllables probably representing the Anglo-Saxon eglæ, egle, a prick or thorn, while the termination is the Dutch eree, ære, a tree. Egisline is frequently alluded to in the writings of English poets, from Chaucer downwards. Milton, in L'Allegro, is thought by the term "twisted egisline" to denote the honeysuckle, Lonicera Periclymenum, which is still known as eglistine in north-east Yorkshire.

EGLETON, EARLS OF. The title of Earl of Eglington has been held by the famous Scottish family of Montgomerie since 1508. The attempts made to trace the descent of this house to Roger of Montgomery, earl of Shrewsbury (d. 1064), one of William the Conqueror's followers, without further examination, and the sure pedigree of the family only begins with Sir John Montgomerie, lord of Eaglesham, who fought at the battle of Otterbourne in
EGMONT, EARLS OF

1388 and died about 1398. His grandson, Sir Alexander Montgomerie (d. c. 1400), was made a lord of the Scottish parliament about 1445 as Lord Montgomerie, and Sir Alexander's great-grandson Hugh, the 3rd lord (c. 1456–1545), was created earl of Eglinton and in 1458 he was a supporter of James V, was succeeded by his grandson Hugh (d. 1546), and then by the latter's son Hugh (c. 1531–1585), who became 3rd earl of Eglinton. This nobleman was a firm supporter of Mary queen of Scots, for whom he fought at Langside, and of the Roman Catholic Church; his son and successor, Hugh, was murdered in April 1586 by the Cunninghams, a family with which his own had an hereditary blood feud. In 1608, by the death of Hugh, the 5th earl, the male line of the Montgomeries became extinct.

Having no children Earl Hugh had settled his title and estates on his cousin, Sir Alexander Seton of Foulstruther (1588–1661), a younger son of Robert Seton, 1st earl of Winton (c. 1550–1603), and his wife Margaret, daughter of the 3rd earl of Eglinton. Alexander, who thus became the 6th earl of Eglinton and took the name of Montgomerie, was commonly called Greyestiel; he was a prominent Covenanter and fought against Charles I at Marston Moor. Later, however, he supported the cause of Charles II., and fell into the hands of Cromwell, who imprisoned him. His fifth son, Robert Montgomerie (d. 1684), a soldier of distinction, fought against Cromwell at Dunbar and at Worcester, afterwards escaping from the Tower of London and serving in Denmark. Robert's elder brother, Hugh, 7th earl of Eglinton (1653–1660), who also fought against Cromwell, was the grandfather of Alexander, the 9th earl (c. 1650–1729), who married, for his third wife, Susannah (1685–1730), daughter of Sir Archibald Kennedy, Bart., of Culzean, a lady celebrated for her wit and beauty. Alexander, the 10th earl (1723–1769), a son of the 9th earl, was one of the first of the Scottish landowners to carry out improvements on his estates. He was shot near Ardrossan by an excise officer named Mungo Campbell on the 24th of October 1769. His brother and successor, Archibald, the 11th earl (1769–1796), raised a regiment of Highlanders with which he served in America during the Seven Years' War. As he left no male issue he was succeeded in the earldom by his kinsman Hugh Montgomerie (1739–1810), a descendant of the 6th earl, who was created a peer of the United Kingdom as Baron Ardrossan in 1806. Before succeeding to the earldom Hugh had served in the American war and had been a member of parliament; after this event he began to rebuild Eglinton castle on a magnificent scale and to construct a harbour at Ardrossan.

This earl's successor was his grandson, Archibald William, the 13th earl (1812–1861), who was born at Palermo in the 20th of September 1812. His father was Archibald, Lord Montgomerie (1773–1874), the eldest son of the 12th earl, and his mother was Mary (d. 1848), a daughter of the 11th earl. Educated at Eton, the young earl's main object of interest for some years was the turf; he kept a large racing stud and won success and reputation in the sporting world. In 1830 his name became more widely known in connexion with the famous tournament which took place at Eglinton castle and is said to have cost him £30,000 or £40,000. This was made the subject of much ridicule and was partly spoiled by the unfavourable weather, the rain falling in torrents. Yet it was a real tournament and the "knights" broke their spears in the orthodox way. Prince Louis Napoleon (Napoleon III.) took part in it, and Lady Seymour, a daughter of Thomas Sheridan and the wife of Lord Seymour, afterwards 12th duke of Somerset, was the queen of beauty. A list of the challengers with an account of the jousts and the melee will be found in the volume on the tournament written by John Richardson, with drawings by J. H. Nixon. It is also described by Disraeli in Endymion. Eglinton was a staunch Tory, and in February 1852 he became lord-lieutenant of Ireland under the earl of Derby. He retired with the ministry in the following December, having by his princely hospitality won himself one of the most popular of Irish viceroyalties. When Derby returned to office in February 1858 he was again appointed lord-lieutenant, and he discharged the duties of this post until June 1859. In this year he was created earl of Winton, an earldom which had been held by his kinsfolk, the Setons, from 1600 until 1716, when George Seton, the 5th earl (c. 1675–1749), was deprived of his titles for high treason. The earl died on 4th October 1861, and was succeeded by his eldest son Archibald William (1841–1892). When this earl died in 1892 his younger brother George Arnulph (b. 1848) became 15th earl of Eglinton and 3rd earl of Winton.

See Sir W. Fraser, Memorials of the Montgomeries, earls of Eglinton (1859).

EGMONT, EARLS OF. John Perceval, 1st earl of Greville (1683–1748), Irish politician and patron, was with J. E. Ogilthorpe in the expedition against the American colony of Georgia, was created earl in 1733. He claimed descent from the Egmonts of Flanders, but his title was taken from the place in County Cork where the family residence stood. Its name of Burton House, and that of Burton manor which formed part of the family estates, were a reminiscence of Burton in Somerset, where was the earlier English family property of his great-great-grandfather Richard Perceval (1599–1650), Burghley's secret agent, and author of a Spanish dictionary published in 1591, whose son Philip Perceval (1605–1647) acquired the Irish estates by judicious use of his opportunities as commissioner for land titles and of his interest at court. Sir Philip's son John, grandfather of the 1st earl, was made a baronet in 1661. The first earl of Greville (who had been made Baron Perceval in 1715, and Viscount Perceval in 1723) is chiefly important for his connexion with the colonization of Georgia, and for his voluminous letters and writings on biography and genealogy.

John Perceval, 2nd earl of Greville (1711–1770), his eldest son, was an active politician, first lord of the admiralty (1763–1766), and political pamphleteer, and like his father an ardent genealogist. He was twice married, and had eight sons and eight daughters. One of his younger sons was Spencer Perceval, prime minister of England. His eldest son succeeded as 3rd earl, and the eldest by his second marriage (with Catherine Compton, baroness of Arden in Ireland) was in 1802 created Baron Arden of the United Kingdom, a title which subsequently became merged in the Egmont earldom.

EGMONT (EGMONT), LAMORAL, count of Gavre (1522–1568), was born in Hainaut in 1522. He was the younger of the two sons of John IV., count of Egmont, by his wife Françoise of Luxemburg, princess of Gavre. On the death of his elder brother Charles, about 1541, he succeeded to his father's estates. In 1547 he served his apprenticeship as a soldier in the expedition of the emperor Charles V. to Algiers, distinguishing himself in the command of a body of cavalry. In 1544 he married Sabina, sister of the elector palatine Frederick III., and the wedding was celebrated at Spires with great pomp in the presence of the emperor and his brother Ferdinand, afterwards emperor. Created knight of the Golden Fleece in 1546, he accompanied Philip of Spain in his tour through the Netherlands towns, and in 1554 he went to England at the head of a special embassy to ask the hand of Mary of England for Philip, and was afterwards present at the wedding ceremony at Winchester. In the summer of 1557 Egmont was appointed commander of the Flemish cavalry in the war between Spain and France; and it was by his vehement persuasion that the battle of St Quentin was fought. The victory was determined by the brilliant charge that he led against the French. The reputation which he won at St Quentin was raised still higher in 1558, when he encountered the French army under de Thermes at Gravelines, on its march homewards after the invasion of Flanders, totally defeated it, and took Marshal de Thermes prisoner. The battle was fought against the advice of the duke of Alva, and the victory made Alva Egmont's enemy. But the count now became the idol of his countrymen, who looked upon him as the saviour of Flanders from the devastations of the French. He was nominated by Philip stadtholder of Flanders and Artois. At the conclusion of the war by the treaty of Cateau Cambresis, Egmont was one of the four hostages selected by the king of France as pledges for its execution.
The attempt made by King Philip to convert the Netherlands into a Spanish dependency and to govern it by Spanish ministers excited the resentment of Egmont and other leading members of the Netherlands aristocracy. Between him and Cardinal Granvelle, the all-powerful minister of the regent Margaret of Parma, there was no love lost. As a member of the council of state Egmont joined the prince of Orange in a vigorous protest addressed to Philip (1561) against the autocratic proceedings of the minister; and two years later he again protested in conjunction with the princes of Orange and Count Fries. In the spring of 1564 Granvelle left the Netherlands, and the malcontents nobles once more took their places in the council of state. The resolve, however, of Philip to enforce the decrees of the council of Trent throughout the Netherlands once more aroused their resentment. Although himself a good Catholic, Egmont had no wish to see the Spanish Inquisition established in his native country. Orange, Egmont and others were convinced that the enforcement of the decrees in the Netherlands was impossible, and, in January 1565, Egmont accepted a special mission to Spain to make known to Philip the state of affairs and the disposition of the people. At Madrid the king gave him an ostentatiously cordial reception, and all the couriers vied with one another in lavishing professions of respect upon him. They knew his vain and somewhat unstable character, and hoped to win him over without conceding anything to the wishes of the Netherlands. The king gave him plenty of flattering promises, but steadily evaded a serious discussion of the object of his mission, and Egmont finally returned home without having accomplished anything. At the same time Philip sent further instructions to the regent to abate nothing of the severity of the persecution.

Egmont was naturally indignant at the treatment he had received, while the terrors of the Inquisition were steadily rousing the people to a state of frenzied excitement. In 1566 a confederacy of the lesser nobility was formed (Les Guerres) whose principles were set out in a document known as the Compromise. From this league Egmont held aloof; he declined to take any step savouring of actual disloyalty to his sovereign. He withdrew to his government of Flanders, and as stadtholder took active measures for the persecution of heretics. But in the eyes of Philip he had long been a marked man. The Spanish king had temporised only until the moment arrived when he could crush opposition by force. In the summer of 1567 the duke of Alva was despatched to the Netherlands at the head of an army of veterans to supersede the regent Margaret and restore order in the discontented provinces. Orange fled to Germany after having vainly warned Egmont and Horn of the dangers that threatened them. Alva was at pains to rouse their suspicions, and then suddenly seized them both and threw them in the castle of Ghent. Their trial was a farce, for their fates had already been determined before Alva left Spain. After some months of imprisonment they were removed to Brussels, where sentence was pronounced upon them (June 4) by the infamous Council of Blood erected by Alva. They were condemned to death for high treason. It was in vain that the most earnest intercessions were made in behalf of Egmont by the emperor Maximilian, by the knights of the order of the Golden Fleece, by the states of Brabant, and by several of the German princes. Vain, too, was the pathetic pleading of his wife, who with her eleven children was reduced to want, and had taken refuge in a convent. Egmont was beheaded at Brussels in the square before the town hall on the day after his sentence had been publicly pronounced (June 5, 1568). He met his fate with calm resignation; and in the storm of terror and exasperation to which this tragedy gave rise Egmont’s failings were forgotten, and he and his fellow-victim to Spanish tyranny were glorified in the popular imagination as martyrs of Flemish freedom. From this memorable event, which Goethe made the theme of his play Egmont (1788), is usually dated the beginning of the famous revolt of the Netherlands. In 1565 a monument to Counts Egmont and Horn, by Fraiken, was erected on the spot where they were beheaded.

**EGOISM** (from Gr. and Lat. _ego_, I, the 1st personal pronoun), a modern philosophical term used generally, in opposition to “Altruism,” for any ethical system in which the good of the individual is the main criterion of moral action. Another form of the word, “Egotism,” is really interchangeable, though in ordinary language it is often used specially (and similarly “egoism,” as in George Meredith’s _Egotist_) to describe the habit of magnifying one’s self and one’s achievements, or regarding all things from a selfish point of view. Both these ideas derive from the original meaning of _ego_, myself, as opposed to everything which is outside myself. This antithesis of ego and non-ego, self and not-self, may be understood in several senses according to the connexion in which it is used. Thus the self may be held to include one’s family, property, business, and an indefinitely wider range of persons or objects in which the individual’s interest is for the moment centred, i.e. everything which I can call “mine.” In this, its widest, sense “a man’s Self is the sum total of all that he can call his” (Wm. James, _Principles of Psychology_, chap x.). This conception of the self belongs mainly to metaphysics and involves the whole problem of the relation between subject and object, the nature of reality, and the possibility of knowledge of self and of object. The ordinary idea of the self as a physical entity, obviously separate from others, takes no account of the problem as to how and in what sense the individual is conscious of himself; what is the relation between subject and object in the phenomenon of self-consciousness, in which the mind reflects upon itself both past and present? This problem is in this case both subject and object, or, as Wm. James puts it, both “I” and “me.” The phenomenon has been described in various ways by different thinkers. Thus Kant distinguished the two selves as rational and empirical, just as he distinguished the two egos as the noumenal or real and the phenomenal from the metaphysical standpoint. A similar distinction is made by Herbart. Others have held that the self has a complex content, the subject self being, as it were, a fuller expression of the object-self (so Bradley); or again the subject self is the active content of the mind, and the object self the passive content which for the moment is exciting the attention. The most satisfactory and also the most general view is that consciousness is complex and unanalyzable.

The relation of the self to the not-self need not be treated here (see _METAPHYSICS_). It may, however, be pointed out that in so far as an object is cognized by the mind, it becomes in a sense part of the complex self-content. In this sense the individual is in himself his own universe, his whole existence being, in other words, the sum total of his psychic relations, and nothing else being for him in existence at all. A similar idea is prominent in many philosophico-religious systems wherein the idea of God or the Infinite is, as it were, the union of the ego and the non-ego, of subject and object. The self of man is regarded as having limitations, whereas the Godhead is infinite and all-inclusive. In many mystical Oriental religions the perfection of the human self is absorption in the infinite, as a ripple dies away on the surface of water. The problems of the self may be summed up as follows. The psychologist investigates the ideal construction of the self, i.e. the way in which the conception of the self arises, the different aspects or contents of the self and the relation of
the subject to the object self. At this point the epistemologist takes up the question of empirical knowledge and considers the kind of validity, if any, which it can possess. What existence has the known object for the knowing subject? The result of this inquiry is generally interpreted to mean that the subject has no existence for the knower except a relative one, i.e. in so far as it is "known" (see RELATIVITY OF KNOWLEDGE). Finally the metaphysician, and in another sphere the theologian, consider the nature of the pure or transcendental self apart from its relations, i.e. the absolute self.

In ethics, egoistic doctrines disregard the ultimate problems of the self and it is assumed the self consists of a man's person, and the things in which he is or ought to be directly interested. The general statement that such doctrines refer all moral action to criteria of the individual's happiness, preservation, moral perfection, raises an obvious difficulty. Egoism merely asserts that the self is all-important in the application of moral principles, and does not in any way supply the material of these principles. It is a purely formal direction, and as such merely an adjunct to a subjective ethical criterion. A practical theory of ethics seeks to establish a particular moral ideal; if it is an absolute criterion, then the altruist would place first the attainment of that ideal by others, while the egoist would seek it for himself. The same is true of ethical theories which may be described as material. Of the second type are those, e.g. of Hobbes and Spinoza, which advocate self-preservation as the ideal, as contrasted with modern evolutionist moralists who advocate race-preservation. Again, we may contrast the early Greek hedonists, who held each man seek the greatest happiness (of whatever kind), with modern utilitarian and social hedonists, who prefer the greatest good or the greatest happiness of the greatest number. It is with hedonistic and other ethical theories that egoism is generally associated. As a matter of fact, however, egoism has been no less prominent in intuitional ethics. Thus the man who seeks only or primarily his own moral perfection is an egoist par excellence. Such are ascetics, hermits and the like, whose whole object is the realization of their highest selves.

The distinction of egoistical and altruistic action is further complicated by two facts. In the first place, many systems combine the two. Thus Christian ethics may be said to insist equally on duty to self and duty to others, while crudely egoistic systems become unworkable if a man renders himself obnoxious to his fellows. On the other hand, every deliberate action based on a supposedly altruistic principle necessarily has a reference to the agent; if it is right that A should do a certain action for the benefit of B, then it tends to the moral self-realization of A that he should do it. Upon whatever principle the rightness of an action depends, its performance is right for the agent. The self-reference is inevitable in every action in so far as it is regarded as voluntary and chosen as being of a particular moral quality.

It is this latter fact which has led many students of human character to state that men do in fact aim at the gratification of their personal desires and impulses. The laws of the state and the various rules of conduct laid down by religion or morality are merely devices adopted for general convenience. The most remarkable statement of this point of view is that of Friedrich Nietzsche, who went so far as to denounce all forms of self-denial as cowardice:—let everyone who is strong seek to make himself dominant at the expense of the weak.

EGORIEVSK, a town of Russia, in the government of Ryazan, 76 m. by rail E.S.W. of Moscow, by a branch line (15 m.) connecting with the Moscow to Ryazan main line. The cotton mills and other factories give occupation to 6000 persons. Egorievsk has important fairs for grain, hides, &c., which are exported. Pop. (1897) 23,932.

EGREMONT. EARLS OF. In 1740 Algernon Seymour, 7th duke of Somerset, was created earl of Egremont, and on his childless death in February 1750 this title passed by special remainder to his nephew, Sir Charles Wyndham or Windham, Bart. (1710-1783), a son of Sir William Wyndham of Orchard Wyndham, Somerset. Charles, who had succeeded to his father's baronetcy in 1740, inherited Somerset's estates in Cumberland and Sussex. He was a member of parliament from 1734 to 1750, and in October 1761 he was appointed secretary for the southern counties, in succession to Pitt. His term of office, during which he held in cordial relations with his brother-in-law, George Grenville, was mainly occupied with the declaration of war on Spain and with the negotiations for peace with France and Spain, a peace the terms of which the earl seems to have disliked. He was also to the fore during the proceedings against Wilkes, and he died on the 21st of August 1763. Horace Walpole perhaps rates Egremont's talents too low, for he says he had neither knowledge of business, nor the smallest share of parliamentary abilities.

The 2nd earl's son and successor, George O'Brien Wyndham (1751-1837), was more famous as a patron of art and an agriculturalist than as a politician, although he was not entirely indifferent to politics. For some time the painter Turner lived at his Sussex residence, Petworth House, and in addition to Turner, the painter Leslie, the sculptor Flaxman and other talented artists received commissions from Egremont, who filled his house with valuable works of art. Generous and hospitable, blunt and eccentric, the earl was in his day a very prominent figure in English society. Charles Greville says, "he was immensely rich and his munificence was equal to his wealth "; and again that in his time Petworth was "like a great inn." The earl died unmarried on the 11th of November 1837, and on the death of his nephew and successor, George Francis Wyndham, the 4th earl (1785-1845), the earldom of Egremont became extinct.

Petworth, however, and the large estates had already passed to George Wyndham (1787-1869), a natural son of the 3rd earl, who was created Baron Leconfield in 1859.

EGREMONT, a market town in the Egremont parliamentary division of Cumberland, England, 5 m. S.S.E. of Whitehaven, on a joint line of the London & North Western and Furness railways. Pop. of urban district (1901) 5761. It is pleasantly situated in the valley of the Ehen. Ruins of a castle command the town from an eminence. It was founded c. 1070 by William de Meschines; it is moated, and retains a Norman doorway and some of the original masonry, as well as fragments of later date. The church of St Mary is a modern reconstruction embodying some of the Norman features of the old church. Iron ore and limestone are raised in the neighbourhood.

It seems impossible to find any history for Egremont until after the Norman Conquest, when Henry I. gave the barony of Copeland to William de Meschines, who erected a castle at Egremont around which the barony grew. The barony afterwards passed by marriage to the families of Lucy and Multon, and finally came to the Percy, earls of Northumberland, from whom are descended the present lords of the manor of Egremont. The earliest evidence that Egremont was a borough occurs in a charter, granted by Richard de Lucy in the reign of King John, which gave the burgesses right to choose their reeve, and set out the customs owing to the lord of the manor, among which was that of providing twelve armed men at his castle in the time of war. The borough was represented by two members in the parliament of 1295, but in the following year was disfranchised, on the petition of the burgesses, on account of the expense of sending members. In 1267 Henry III. granted Thomas de Multon a market every Wednesday at Egremont, and a fair every year on the eve, day and morrow of the Nativity of the Virgin Mary. In the Quo Warranto rolls he is said to have claimed by prescription an another weekly market on Saturday. The market rights were purchased from Lord Leconfield in 1885, and the market on Saturday is still held. Richard de Lucy's charter shows that dyeing, weaving and fulling were carried on in the town in his time.

EGRESS (Lat. egressus, going out), in astronomy, the end of the apparent transit of a small body over the disk of a larger one; especially of a transit of a satellite of Jupiter over the disk of that planet. It designates the moment at which the smaller body is seen to leave the limb of the other.
EGYPT

In the following account a division is made into (I.) Modern Egypt, and (II.) Ancieni Egypt; but the history from the earliest times is given as a separate section (III.).

Section I. includes Geography, Economics, Government, Inhabitants, Finance and Army. Section II. is subdivided into—(A) Exploration and Research; (B) The Country in Ancient Times; (C) The Modern Nile Delta. The sections of (A) and (B) are mainly notes by the writer in Egyptology; (F) Chronology. Section III. is divided into three main periods:—(1) Ancient History; (2) The Mahomedan Period; (3) Modern History (from Mehemet Ali).

I. MODERN EGYPT

Boundaries and Areas.—Egypt is bounded N. by the Mediterranean, S. by the Anglo-Egyptian Sudan, N.E. by Palestine, E. by the Red Sea, W. by Tripoli and the Sahara. The western frontier is ill-defined. The boundary line between Tripoli and Egypt is usually taken to start from a point in the Gulf of Sollum and to run S. by E. so as to leave the oasis of Siwa to Egypt. South of Siwa the frontier, according to the Turkish firman of 1841, bends eastward, approaching the cultivated Nile-land near Wadi Halfa, i.e., the southern frontier. This southern frontier is fixed by agreement between Great Britain and Egypt at the 22° N. The N.E. frontier is an almost direct line drawn from Taba, near the head of the Gulf of Akaba, the eastern of the two gulfs into which the Red Sea divides, to the Mediterranean at Rafa in 34° 15' E. The peninsula of Sinai, geographically past Arabia, is included in the Egyptian dominions. The total area of the country is about 386,600 sq. m., or more than three times the size of the British Isles. Of this area 4% is desert. Canals, roads, date plantations, &c., cover 1900 sq. m.; 2830 sq. m. are comprised in the surface of the Nile, marshes, lakes, &c. A line corresponding with the 30° N., drawn just S. of Cairo, divides the country into Lower and Upper Egypt, natural divisions in common use, Lower Egypt between Suez and Cairo and Upper Egypt between Cairo and the Nile. The Arab Low Egypt is called Er-Rif, the cultivated or fertile; Upper Egypt Es Sa'id, the happy or fortunate. Another division of the country is into Lower, Middle and Upper Egypt, Middle Egypt in this classification being the district between Cairo and Assiut.

General Character.—The distinguishing features of Egypt are the Nile and the desert. But for the river there would be nothing to differentiate the country from other parts of the Sahara. The Nile, however, has transformed the land through which it passes. Piercing the desert, and at its annual overflow depositing rich sediment brought from the Abyssinian highlands, the river has created the Delta and the fertile strip in Upper Egypt. This cultivable land is Egypt proper; to it alone is applicable the ancient name—"the black land." The Mirs of the Arabs is restricted to the same territory. Beyond the Nile valley east and west stretch great deserts, containing here and there fertile oases. The general appearance of the country is remarkably uniform. The Delta is a level plain, richly cultivated, and varied alone by the lofty dark-brown mounds of ancient cities, and the villages set in groves of palm-trees, standing on mounds often, if not always, ancient. Groves of palm-trees are occasionally seen besides those around the villages, but other trees are rare. In Upper Egypt the Nile valley is very narrow and is bounded by mountains of no great height. They form the edge of the desert on either side of the valley, of which the bottom is level rock. The mountains rarely take the form of peaks. Sometimes they approach the river in bold promontories, and at others are divided by the dry beds of ancient water-courses. The bright green of the fields, the reddish-brown or dull green of the great river, contrasting with the bare yellow rocks, seen beneath a brilliant sun and a deep-blue sky, present views of great beauty. In form the landscape varies little and is not remarkable; in colour its qualities are always splendid, and under a general uniformity show a continual variety.

1 By the Greek and Roman geographers Egypt was usually assigned to Libya (Africa), but by some early writers the Nile was thought to mark the division between Libya and Asia. The name occurs in Homer as Aphygenv, but is of doubtful origin.

The Delta Region.—Egypt has a coast-line of over 200 m. on the Mediterranean and about 125 m. on the Red Sea. The Mediter-

ranean coast extends from the Gulf of Sollum on the west to Rafa on the east. From the gulf to the beginning of the Delta the coast is straight and level, but slightly indented on the east. The cliffs attain in places a height of 1000 ft. They are the termination of a stony plateau, containing several small oases, which southward joins the more arid and uninhabitable wastes of the Libyan desert. Occasionally, limestone rocks, is low, with cape-like projections at the Nile mouths formed by the river silt. Two bays are thus formed, the former being the coast of the day of Aboukir. It is indicated by a point near the ancient Canopic mouth, eastward by the Rosetta mouth. Beyond the Delta eastward the coast is again barren and without harbours. It rises gradually southward, merging into the plain of the Sinal peninsula. The Red Sea coast is likewise most mountainous. The mountains are the northern continuation of the Abyssinian table-land, and some of the peaks are over 6000 ft. above the sea. The highest peak is 12,630 ft. high; others are Ghurib, Dukhan, Es Shabiy, Fatira, Abu Tur, Zubara and Hamad (Hamata). The coast has a general N.N.W. and S.S.E. trend, and save for the two gulfs in which it is divided by the massif of Sina, is not deeply indented. Where the frontier between Egypt and the Sudan reaches the sea is Ras Elba (see further Red Sea).

The Nile Valley (see also NILE).—Entering Egypt proper, a long series of the Sederi or Sederi Table-land lies between the Nile in sandstone beds of Cretaceous age as far as 25° N., and throughout this part of its course the valley is extremely narrow, rarely exceeding 2000 ft. in width. At this stage the river contains, annually, about 150,000,000 cu. yds., being only 170 yds. wide and the river over 100 ft. deep—and Assuan (First Cataract), the course of the river is interrupted by a series of rapids, each of which is a natural dam, by the excavation of the or daybreaks formed by the egression of the Nile. The area of the valley is a table-land of islands, with Numerous small rapids, which are described not very accurately as cataracts; no good evidence exists in support of the notion that they are natural rock breaks and cut down and carried away by some sudden convulsion. From 25° N. northwards for 518 m. the valley is of the "rift-valley" type, a level depression, bounded in a limestone wall, overhung on the north above being 100 yds. wide. The river over 100 ft. deep, and nowhere more than 50 ft. wide, and with the water stage in spring and autumn, shallow. The average width of the cultivated land is about 10 m., of which the greater part lies on the left (western) bank of the river; and on the south of this is a belt, varying from a few hundred yards to 3 or 4 m., of stony and sandy ground, reaching up to the foot of the limestone cliffs, which rise in places to as much as 1000 ft. above the valley. This continues as far as 25° N., after which the hills that close the river valley become lower, and the higher plateaus lie at a distance of 50 or 50 m. back in the desert.

The Fayum.—The fertile province of the Fayum, west of the Nile and separated from it by a belt of sandy desert, seems to owe its existence to movements similar to those which determined the valley itself. Lying in a basin sloping in a series of terraces from an altitude of 1000 ft. east to almost sea-level west, it is deeply watered on the north-west, at the margin of the Birket-el-Kerun, this province is wholly irrigated by a canalized channel, the Bahr Yusef, which, leaving the Nile at Derut el Sheir in Upper Egypt, follows a line of elevation of the same meridian of latitude on which it has entered the Fayum through a gap in the desert hills by the 11TH dynasty pyramids of Lahun and Hawara (see FAYUM).

The Delta.—About 50° N., where the Nile was the boundary, and the hills which have hitherto run parallel with the Nile turn W.N.W. and E.N.E., and the triangular area between them is wholly deltaic. The Delta measures 100 m. from S. to N., having a width of 135 m. on the shore of the Mediterranean between Alexandria on the west and Port Said on the east. The low sandy shore of the Delta, slowly increasing by the annual deposit of silt by the river, is mostly a belt of sand-hills and sandy waste. This is the valley of the lagoons and marshes immediately behind the coast-line. Southwards the quality of the soil rapidly improves, and becomes the finest soil of Egypt, and the greatest part of the Delta is made up by the accumulation of this soil. The length enters the Fayum through a gap in the desert hills by the 11TH dynasty pyramids of Lahun and Hawara (see FAYUM).
northern limits of the Delta this cannot, however, be depended on, since the deep water at these depths has proved on several occasions to be salt. The surface of the Delta is a wide alluvial plain sloping gently towards the sea, and having an altitude of 29 ft. above it at its highest point. There are no permanent lakes or swamps except at the higher ground of the deserts, to which the silt-laden waters of the Nile in flood time cannot reach. This silt consists largely of alkalies (about 12% of calcium carbonate (18%)) with smaller quantities of silica, oxide of iron and carbon. Although the Nile water is abundantly charged with alluvium, the annual deposit by the river, except under extraordinary circumstances, is smaller than might be supposed. The mean ordinary rate of the increase of the soil of Egypt is calculated as about 44 in. in a century.

The Lakes.—The lagoons or lakes of the Delta, going from west to east, are Mairo, Motruf (Maiuru), Ebrus, Bursul and Manzala. The land separating them from the Mediterranean is nowhere more than 10 m. wide. East of the Damietta mouth of the Nile this strip is in places not more than 200 yds. broad. All the lakes are shallow and the water in summer brackish. Maretotis, which bounds Alexandria on the south side, varies considerably in area, rising to fall of the Nile; when the Nile is low there is a lake, admitting of marsh, when at its highest the lake covers about 100 sq. m. In ancient times it was navigable and was joined by various canals to the Nile. The dry land around was cultivated and produced the famous Maretotis. The canals being neglected, the lake decreased in size, though it was still of fertile area in the 15th and 16th centuries, and was then noted for the value of its fisheries. When the French army occupied Egypt in 1798 Maretotis was found to be a sandy plain. In April 1801 the British army was through the land between Aboukir and Bursul, and eastwards to reach the waters of the sea through the ancient barges of Maretotis and laying up in a shallow area then in cultivation. This precipitous descent was attempted by the Turks in 1803 and a second time by the British in 1807. Maretotis has no outlet, and the water is kept at a uniform level by means of powerful pumps which neutralize the effect of the river. A western arm has been cut off from the lake by a dyke, and in this arm a thick crust of salt is formed each year after the evaporation of the flood water. Near the shores of the lake wild flowers grow in rich profusion. Like all the Delta lakes, Maretotis abounds in wild-fowl. North-east of Maretotis was Lake Aboukir, a small sheet of water, now dry, lying S.W. of Aboukir Bay. East of this reclaimed marsh and reaching to within 4 m. of the Rosetta branch of the Nile, lies Idku, 22 m. long and in places 16 m. wide, with an opening, supposed to be the ancient Canopic mouth of the Nile, into Aboukir Bay. Bursul begins a little eastward of this lake. Rosetta and stretches bow-shaped for 64 m. Its greatest width is about 16 m. Joining it S.E. is an expanse of sandy marsh. Several canals or canalsized channels enter the lake. Opposite the spot where the Bahr-mit Yeur enters is a retaining wall, the Mediterranean Canal and opening indicate the course of the ancient Sebennytic branch of the Nile. Bursul is noted for its water-melons, which are yellow within and come into season after those of the Nile.

Manzala greatly exceeds the other Delta lakes in size, covering over 780 sq. m. It extends from very near the Damietta branch of the Nile, Port Said. It receives the waters of the canalsized channels which were once the Tanitic, Mendesian and Pelusiac branches. The northern shore is separated from the sea by an extremely narrow strip of land, across which, when the Mediterranean is stormy and the lake full, the waters meet. Its average length is about 40 m., and its average breadth about 15. The depth is greater than that of the other lakes, and the water is salt, though mixed with fresh. It contains a large number of islands, and the whole lake abounds in waterfowl of various kinds. Of the islands Tennis (anciently Teneuse) contains ruins of the Roman period. The lake supports a considerable population of fishermen, who dwell in villages on the shore and islands and live upon the fish of the lake. The reeds are cover for waterfowl of various kinds, which the traveller sees in great numbers, and white herons are found in the marshes near the mouth of the Nile. The inhabitants of the Datta is the site of Serbonis, another one end up lake, which had the general characteristics of the Delta lagoons. In the Isthmus of Suez are Lake Timaa and the Great and Little Gitter Lakes, occupying part of the ancient land of the Red Sea. All three were dry or marshy depressions previously to the cutting of the Suez Canal, at which time the waters of the Mediterranean and Red Sea were connected through them (see Suez Canal).

A chain of natron lakes (seven in number) lies in a valley in the western desert, 70 to 90 m. N.W. of Cairo. In the Fayum province further south is the Birket-el-Kerun, a lake, lying below the level of the Nile, some 30 m. long and 5 wide at its broadest part. Kerun is all that is left of the Lake of Moeris, an important body of water which played an important part in the inundation schemes of the Pharaohs. The water of el-Kerun is brackish, though deprived of brine, which has at all seasons a much higher level. It is bounded on the north by the Libyan Desert, which rises a bold range of mountains; and it has a strange and picturesque wilderness. Near the lake are several sites of ruined towns, and the temple called Kasr-Kurun, dating from Roman times, distinguishes the most important of these. South-west of the Fayun are the Wadi Rayan, a large and deep depression, utilizing from the Nile, the desert, and the Wadi Rayan, on the coast of the Mediterranean, the most important of these. North of Assuan it is called the Libyan Desert. In the north the desert plateaux are comparatively low, but from Cairo southwards they rise to 1000 and even 1500 ft. above sea level. Formed mostly of horizontal strata of varying hardness, they present a series of terraces of minor plateaux, rising one above the other and intersected by small ravines worn by the occasional rainstorms which burst in their neighbourhood. The weathering of this desert area is probably fairly rapid, and the agents at work are principally the rapid heating and cooling of the rock, the constant dry and the ephemeral action of sand which occasionally falls on the softer strata; these, aided by the occasional rain, are ceaselessly at work, and produce the successive plateaux, dotted with small isolated hills and cut up by valleys (wadis) which occasionally drain down from the scarped cliffs, thus forming the principal type of scenery of these deserts. From this it will be seen that the desert in Egypt is mainly a rock desert, where the surface is formed of disintegrated rocks of which have been carried away by the wind; and east of the Nile this is almost exclusively the case. Here the desert meets the line of mountains which runs parallel to the Red Sea and the Gulf of Suez in the western desert, however, those large sand accumulations which are usually associated with a desert are met with. They occur as lines of dunes formed of rounded grains of quartz, and lie in the direction of the prevalent wind, usually being of small breadth as compared with their length; but in certain areas, such as that lying S.W. and W. of the oases of Farafra and Dakhla, these lines of dunes, lying parallel to each other and about half a mile apart, cover immense areas, rendering them absolutely insurmountable.

Plateaus.

From the southern borders of Egypt to the Delta in the north, the plateau extends on either side of the Nile valley. The Red Sea plateau is characterized by the linear arrangement of orderly plateaux, rising one above the other, and intersected by small intermittent rifts, worn by the occasional rainstorms which burst in their neighbourhood. The weathering of this desert area is probably fairly rapid, and the agents at work are principally the rapid heating and cooling of the rock, the constant dry and the ephemeral action of sand which occasionally falls on the softer strata; these, aided by the occasional rain, are ceaselessly at work, and produce the successive plateaux, dotted with small isolated hills and cut up by valleys (wadis) which occasionally drain down from the scarped cliffs, thus forming the principal type of scenery of these deserts. From this it will be seen that the desert in Egypt is mainly a rock desert, where the surface is formed of disintegrated rocks of which have been carried away by the wind; and east of the Nile this is almost exclusively the case. Here the desert meets the line of mountains which runs parallel to the Red Sea and the Gulf of Suez in the western desert, however, those large sand accumulations which are usually associated with a desert are met with. They occur as lines of dunes formed of rounded grains of quartz, and lie in the direction of the prevalent wind, usually being of small breadth as compared with their length; but in certain areas, such as that lying S.W. and W. of the oases of Farafra and Dakhla, these lines of dunes, lying parallel to each other and about half a mile apart, cover immense areas, rendering them absolutely insurmountable.
except in a direction parallel to the lines themselves. East of the oases of Baharia and Farafra is a very striking line of these sand dunes, extending for more than 3 miles and dividing diversely from Moghara in the north, passing along the west side of Kharga Oasis to a point near the Nile in the neighbourhood of Abu Sinub, a distance of nearly 150 m. In the northern part of this desert the dunes are irregular and not very prominent; but farther south, they incline more towards the meridian, becoming at last very nearly north and south.

Moghara—In the western desert lie the five large oases of Egypt, namely, Siwa, Baharia, Farafra, Dakhla and Kharga or Great Oasis, occupying depressions in the plateau or, in the case of the last three, large areas on the western face of the large accumulations of sand which encircle the western versant of the Nile valley hills. Their fertility is due to a plentiful supply of water furnished by a sandstone bed 300 to 500 ft. below the surface, whence the water rises through natural fissures or artesian borrows to the surface, and sometimes to several feet above it. These oases were known and occupied by the Egyptians as early as 1600 b.c., and Kharga (q.v.) rose to special importance in the ancient inscriptions. Many of the cultivated desert areas and at the cataracts are covered with a highly polished film, of almost microscopic thinness, consisting chiefly of oxides of iron and sand, forming as delightful red sandstone, and often to be due to a chemical change within the rock and not to deposition on the surface.

Minerals.—Egypt possesses considerable mineral wealth. In ancient times, gold and precious stones were mined in the Red Sea hills. During the Moslem period mining was abandoned, and it was not until the beginning of the 20th century that renewed efforts were made. Operations were started in March of this year. Another mine opened in 1905 was that of Um Garait, E. E. N. of Korosko, and 65 m. distant from the Nile.

Gold-mining recommenced in 1905 at Um Rus, a short distance inland from the Red Sea and some 50 m. S. of Koseir, where mining operations were started in March of this year. Another mine opened in 1905 was that of Um Garait, E. E. N. of Korosko, and 65 m. distant from the Nile.

Grazia.—Part of Upper Egypt is within the tropics, but the greater part of the country is north of the Tropic of Cancer. Except a narrow belt on the north along the Mediterranean shore, Egypt lies in an almost rainless area, where the temperature is high by day and low by night. The climate is most affected by the cloudless sky. The mean temperature at Alexandria and Port Said varies between 57° F. in January and 81°F. in July; while at Assuan the temperatures are somewhat higher, reaching 90°F. in January, rising to 84°F. in July. January is the coldest month, when occasionally in the Nile valley, and more frequently in the open desert temperatures may fall to 30°F. The mean temperature at Cairo and 110° F. for Cairo. Farther south the range of temperature becomes greater as the true desert conditions are reached. Thus at Assuan the mean maximum is 118° F., the mean minimum 42° F. At Wadi Halfa the figures in each case are one degree lower.

The relative humidity varies greatly. At Assuan the mean value for the year is only 38%, that for the summer being 55%, and for the winter 11%; while for Wadi Halfa the mean is 32%, and 20% and 42% are the mean values for summer and winter respectively. A white fine and dense, and sometimes rises from the Nile in the morning, but it is short duration and rare occurrence. In Alexandria and on all the Mediterranean coast of Egypt rain falls abundantly in the winter months, amounting to 8 in. in the year; southwards it rapidly decreases, and a south of 35° little noise falls.

Records at Cairo show that the rainfall is very irregular, and is frequently accompanied by sudden downpours. On the average for the rainy season; still, most falls in the winter months, especially December and January, while, on the other hand, none has been recorded in June and July. The average annual rainfall does not exceed 1-90 in. In the interior, between desert rains, at a distance of 200 miles, are unknown, and from time to time heavy storms burst, causing sudden floods in the narrow ravines, and drowning both men and animals. These are mounted common in the mountainous region of the Sinai Peninsula, where they are much dreaded by the Arabs. Snow is unknown in the Nile valley, but on the mountains of Sinai and the highlands of the southwest, and continuous snow, of a temperature of 18° F. At an altitude of 2000 ft. has been recorded in January.

The atmospheric pressure varies between a maximum in January and a minimum in July, the mean difference being about 0.29 in.
In a series of records extending over 14 years the mean pressure varies as low as 29.63 in.

The most striking meteorological feature in Egypt is the persistence of the north wind throughout the year, without which the climate would be very trying. This is the "Buraq" wind which enables sailing boats comparatively to avoid the Nile against its current and in rapid current. In December, January and February, at Cairo, the north wind slightly predominates, though those from the south and west ("Khamseen") are frequent. But, after late March, the wind becomes continuously for the rest of the year. In May and June the prevailing direction is north and north-north-east, and for July, August, September, October and November north and north-west. Frequently, and in observations that exist, it seems that farther south the southern winter winds decrease rapidly, becoming westerly, until at Assuan and Wadi Halfa the northerly winds are almost invariably throughout the year. Among the most usual customs of the region of the winds of the months, come invariably from the south. They are preceded by a rapid fall of the barometer for about a day, until a gradient from south to north is formed, and the heavy fog, high and foggy, from the south-east; rapidly increasing in violence, it shifts through south to south-west, finally dropping about sunset. The same effect is seen both in the waste tracts of uncultivated land near the Mediterranean, and it is often fatal in its appearance that one finds it difficult to admit the illusion.

Flora.—Egypt possesses neither forests nor woods, and, as practi- cally no one of the species is in the same way successfully adapted to agriculture, the flora is limited. The most important tree is the date-palm, which grows all over Egypt and in the oases. Formerly, the date was grown regularly in the oases, but extensive cultivation has been abandoned, the trees have been cut down, and the road beds and trees are seen only on the cultivated land. The mulberry tree is common in Lower Egypt. The sun tree (Acacia nilotica) grows everywhere, as well as the tamarisk and the hyacinth. In the desert holiday is very common, and the date is grown as a fruit tree. In the northern part of the country the fruit is not so abundant, and the dates are large and very large employed. The weeping-willow, myrtle, elm, cypresses, and eucalyptus are also used in the gardens and plantations. The dates of the fruit are nearly thirty varieties, which are sold half-ripe, ripe, dried, and pressed in their fresh moist state in mats or skins. The pressed dates of Siwa are particularly esteemed. Goose, duck, and the other birds are abundant. The white goose is the white-fronted variety; the Egyptian goose is more rare. Both varieties are depicted on the ancient monuments; the white-fronted goose being commonly represented. Several birds of gorgeous plumage come north into Egypt in the spring and summer, and include, the golden oriole, the sun-bird, the roller, and the blue-checked bee-eater.

Egypt as a Health Resort.—The country is largely resorted to during the winter months by Europeans in search of health as well as pleasure. Upper Egypt is healthier than Lower Egypt, where, especially near the coast, malarial fevers and diseases of the respiratory organs are not uncommon. The least healthy time of the year is the latter part of autumn, when the inundated soil is drying. In the desert, at a very short distance from the cultivated land, the climate is uniformly dry and unvariedly healthy. The most suitable, places for the residence of Europeans are towards the south, where there are natural mineral springs, in the desert, 14 m. S. of Cairo, and Luxor and Assuan in Upper Egypt.

The diseases from which Europeans suffer are very largely the result of insanitary surroundings. In this respect a great improvement has taken place since the British occupation in 1882. Plague, formerly one of the great plagues and most dangerous, has been stamped out, the last visitation having been in 1844, but cholera epidemics occasionally occur. Cholera rarely extends south of Cairo. In 1848 it is believed that over 200,000 persons died from cholera, but not more than 700 in one year. The white fronted goose is the common, and skin diseases are numerous, but the two most prevalent diseases among the Egyptians are dysentery and opthalmia. The abatement of these diseases by the British Government is the result of a careful investigation of the sanitary condition as revealed by the visitation of a European official.

1 A vivid description of Cairo during the prevalence of plague in 1835 will be found in A. W. Kingslake's "Egypt."
Chief Towns.—Cairo (q.r.), the capital, a city of Arab foundation, is built on the east bank of the Nile, about 12 m. above the point where the river divides, and in reference to its situation at the head of the Delta has been called by the Arabs "the diamond stud in the handle of the fan of Egypt." It has a population of 644,476. The railway is altered in length. Next in importance of the cities of Egypt and the chief seaport is Alexandria (q.e.), pop. (with Ramleh) 370,000, on the shore of the Mediterranean at the western end of the Delta. Port Said (q.e.), pop. 49,884, at the eastern end of the Delta, and at the north entrance to the Suez Canal, is the second seaport. Between Alexandria and Port Said are the towns of Rosetta (q.e.), pop. 16,810, and Damietta (q.e.), pop. 29,334, each built a few miles above the mouth of the branch of the Nile of the same name. In the middle ages, when Alexandria was in decay, these two towns were busy ports; with the revival of Alexandria under Mehemet Ali and the foundation of Port Said (c. 1860), their trade declined. The other ports of Egypt are Suez (q.e.), pop. 18,347, at the south entrance of the canal, Kosseir (794) on the Red Sea, the seat of the trade carried on between Upper Egypt and Arabia, Mersa Mattrah, near the Tripolitan frontier, and El-Arish, pop. 5907, on the Mediterranean, near the frontier of Palestine, and a halting-place on the caravan route from Egypt to Syria. In the interior of the Delta are many flourishing towns, the largest being Tanta, pop. 54,437, which occupies a central position. Damahur (38,752) lies on the railway between Tanta and Alexandria; Mansura (40,279) is on the Damietta branch of the Nile, to the N.E. of Tanta; Zagazig (34,990) is the largest town in the Delta east of the Damietta branch; Bilbeis (33,448) lies N.N.E. of Cairo, on the edge of the desert and in the ancient Land of Goshen. Ismailia (10,373) is situated midway on the Suez Canal. All these towns, which depend largely on the cotton industry, are separately noticed.

Other towns in Lower Egypt are: Mehallet el-Kubra, pop. 47,955, 16 m. by rail N.E. of Tanta, with manufactories of silk and cottons; Sallbiah (6100), E.E.N.E. of and terminus of a railway from Zagazig, on the edge of the desert south of Lake Menzala, and the starting-point of the caravans to Syria; Mataria (15,143) on Lake Menzala and headquarters of the fishing industry; Zifta (15,850) on the Damietta branch and the site of a barrack; Samanud (14,528), also on the Damietta branch, noted for its pottery, and Fua (14,515), where large quantities of tarbushes are made, on the Rosetta branch. Shibin el-Kom (21,576), 16 m. S. of Tanta, is a cotton centre, and Menfou (22,516), 8 m. S.W. of Shibin, in the fork between the branches of the Nile, is the chief town of a rich agricultural district. There are many other villages in the Delta with populations between 10,000 and 20,000.

In Upper Egypt the chief towns are nearly all in the narrow valley of the Nile. The exceptions are the towns in the oases comparatively unimportant, and those in the Fayum province. The capital of the Fayum, Medinet el-Fayum, has a population (1907) of 37,320. The chief towns on the Nile, taking them in their order in ascending the river from Cairo, are Beni Suef, Minia, Assiut, Akhmim, Suhag, Girga, Kena, Luxor, Edfu, Assuan and Asyut. Beni Suef (23,557) is 77 m. from Cairo by rail. It is on the west bank of the river, is the capital of a mudiria and a centre for the manufacture of woollen goods. Minia (27,221) is 77 m. by rail farther south. It is also the capital of a mudiria, has a considerable European colony, possesses a large sugar factory and some cotton mills. It is the starting-point of a road to the Baharia oasis. Assiut (6,808), pop. 30,484, is 235 m. S. of Cairo by rail, and is the most important commercial centre in Upper Egypt. At this point a barrage is built across the river. Suhag (17,514) is 56 m. by rail S. of Assiut and is the headquarters of Girga mudiria. The ancient and celebrated Coptic monasteries El Abiad (the white) and El Ahmar (the red) are 3 to 4 m. W. and N.W. respectively of Suhag. A few miles above Suhag, on the opposite (east) side of the Nile is Akhmim (q.r.) or Ekhmim (23,795), where silk and cotton operatic are made. Girga (q.e.), pop. 101,803, is 27 m. S. by rail of Suhag, and on the same (the west) side of the river. It is noted for its pottery. Kena (q.r.), pop. 20,060, is on the east bank of the Nile, 145 m. by rail from Assiut. It is the chief seat of the manufacture of the porous earthenware water-bottles used all over Egypt. Luxor (q.e.), pop. (with Karnak) 25,229, marks the site of the Thebes. It is 418 m. from Cairo, and here the gauge of the railway is altered. 101,103, is another place where pottery is made in large quantities. It is on the west bank of the Nile, 36 m. by rail S. of Luxor. Edfu (q.r.), pop. 19,262, is also on the west side of the river, 30 m. farther south. It is chiefly famous for its ancient temple. Assuan (q.e.), pop. 12,618, is at the foot of the First Cataract and 531 m. S. of Cairo by rail. Three miles farther south, at Shelleh, the Egyptian railway terminates. Korosko, 118 m. by river above Assuan, is a small place notable as the northern terminus of the caravan route from the Sudan across the Nubian desert. Since the building of the railway—which starts 96 m. higher up, at Wadi Halfa—to Khartum, this route is little used, and Korosko has lost what importance it had.

Ancient Cities and Monuments.—Many of the modern cities of Egypt are built on the sites of ancient cities, and they generally contain some monuments of the time of the Pharaohs, Greeks or Romans. The sites of other ancient cities now in complete ruin may be indicated. Memphis, the Pharaonic capital, was on the west bank of the Nile, some 14 m. above Cairo, and Heliopolis lay some 5 m. N.N.E. of Cairo. The pyramids of Giza or Gete, on the edge of the desert, 8 m. west of Cairo, are the largest of the many pyramids and other monuments, including the famous Sphinx, built in the neighbourhood of Memphis. The site of Thebes has already been indicated. Syene stood near to where the town of Assuan now lies; opposite, on an island in the Nile, are scanty ruins of the city of Elephantine, and a little above, on another island, is the temple of Philae. The ancient Coptos (Keft) is represented by the village of Kuf, between Luxor and Kena. A few miles north of Kena is Dendera, with a famous temple. The ruins of Abydos, one of the oldest places in Egypt, are 8 m. S.W. of Balliana, a small town in Girga mudiria. The ruined temples of Abu Simbel are on the west side of the Nile, 56 m. above Korosko. On the Red Sea, south of Kosseir, are the ruins of Myos Hormos and Berenice. Of the ancient cities in the Delta there are remains, among others, of Saia, Iseum, Tanis, Bubastis, Onis, Sebennytus, Pithom, Pelusium, and of the Greek cities Naucratis and Daphne. There are, besides the more ancient cities and monuments, a number of Coptic towns, monasteries and churches in almost every part of Egypt, dating from the early centuries of Christianity. The monasteries, or "deserts," are generally fort-like buildings and are often built in the deserts. Tombs of Mahommedan saints and holy men are often placed on the summit of the cliffs overlooking the Nile. The traveller in Egypt thus views, side by side with the activities of the present day, where occident and orient meet and clash, memorials of every race and civilization which has flourished in the valley of the Nile.

Trade Routes and Communications.—Its geographical position gives Egypt command of one of the most important trade routes in the world. It is, as it were, the fort which commands the way from Europe to the East. This has been the case from time immemorial, and the provision, in 1860, of direct maritime communication between the Mediterranean and the Red Sea, by the completion of the Suez Canal, ensured for the Egyptian route the supremacy in sea-borne traffic to Asia, which the discovery of the passage to India by way of the Cape of Good Hope had menaced for three and a half centuries. The Suez Canal is 87 m. long, 66 actual canal and 21 lakes. It has sufficient depth to allow vessels drawing 27 ft. of water to pass through. It is administered by a company whose headquarters are in Paris, and no part of its revenue reaches the Egyptian exchequer (see SUEZ CANAL). Besides the many steamship lines which use the Suez Canal, other steamers run direct from European ports to Alexandria. There is also a direct mail service between Suez and Port Sudan.

The chief means of internal communication are, in the Delta the railways, in Upper Egypt the railway and the river. The railways

There are three agricultural seasons: (1) summer (from July to September), (2) winter (November to March), and (3) spring (April to June). In the Nile Delta, where the climate is more Mediterranean, crops are planted in autumn and harvested in spring. In the southern desert areas, crops are planted in winter and harvested in summer.

Egyptian agriculture is highly developed due to the presence of the Nile River, which provides water for irrigation. The most important crops include cotton, sugar, rice, and vegetables. The cotton grown in Egypt is of high quality and is exported to many countries around the world.

Fishing is also an important activity along the Nile River. Fish such as tilapia, barb, and catfish are commonly caught. These fish are sold locally and also exported.

Vegetables and Fruits: Among the vegetables grown in Egypt are lettuce, tomatoes, cucumbers, and onions. Fruits such as oranges, lemons, and grapes are also grown.

Manufactures and Native Industries: Egypt has a rich history of textile production, especially cotton. The country is also known for its handicrafts, including pottery, metalwork, and jewelry. Additionally, Egypt has a significant fishing industry, producing a variety of seafood.

The agricultural industry of Egypt is closely linked to the seasonal cycle of the Nile River, and farming practices have evolved over centuries to adapt to the changing conditions of the river.
possess rice mills. Flour mills are found in every part of the country, the maize and other grains being grown for home consumption. Soap-making and leather-tanning are carried on, and there are breweries at Alexandria and Cairo. The manufacture of tobacco into cigarettes, carried on largely at Alexandria and Cairo, involves the export of tobacco. Native industries include the weaving of silk, woolen, linen and cotton goods, the hand-woven silk shawls and draperies being often rich and elegant. The silk looms are chiefly at Mehallet el-Kubra, Cairo and Damietta. The Egyptians are noted for the making of pottery of the commoner kinds, especially water-jars. There is at Cairo and in other towns a considerable industry in ornamental wood and metal work, inlaying with ivory and pearl, brass trays, jewellery, vessels, gold and silver ornaments, &c. At Cairo and in the Fayyum, attar of roses and other perfumes are manufactured. Boat-building is an important trade.

Commerce.—The trade of Egypt has developed enormously since the British occupation in 1882 ensured to all classes of the community the enjoyment of the profit of their labour. The total value of the commerce in the 20 years 1882 to 1901 was £19,000,000 to £34,400,000. The wealth of Egypt lying in the cultivation of its soil, almost all the exports are agricultural produce, while the imports are mostly manufactured goods, minerals and raw materials. The staple export is cotton, cotton seed, sugar, beans, cigarettes, onions, rice and gum-arabic. The gum is not of native production, being in transit from the Sudan to Egypt by hides and skins from the cotton and other grains, wool, quills, lenticils, dates and Sudan produce in transit. The principal articles imported are: cotton goods, cotton yarn and clothing, machinery, flour, alcoholic liquors, petroleum, fruits, coffee and live animals. There is an ad valorem duty of 8% on imports and of about 1% on exports. Tobacco and precious stones and metals pay heavier duties. The tobacco is imported chiefly from Turkey, and sugar from Greece, is made into cigarettes in Egypt, and in this form exported to the value of about £50,000 yearly.

The cotton, all other exports are of minor account. The cotton exported, of which Great Britain takes more than half, is worth over three-fourths of the total value of goods sent abroad. Next to cotton, sugar is the most important article exported. A large proportion of the sugar manufactured is, however, consumed in the country and does not figure in the trade returns. Of the imports the largest single item is cotton goods, nearly all being sent from England. Woollen goods come chiefly from England, Austria and Germany, silk goods from France. Large quantities of ready-made clothes and fees are imported from Austria. Iron and steel goods, machinery, locomotives, &c., come chiefly from England, Austria and Germany, coal from England, live stock from Turkey and the Red Sea ports, coffee from Brazil, timber from Russia, Turkey and Sweden.

A British consular report (No. 3121, annual series), issued in 1904, shows that in the period 1887-1902 the import trade of Egypt nearly doubled. In the same period the proportion of imports from the United Kingdom to Egypt increased from 8.4% in 1887 to 18% in 1902. The imports and also the exports increased, and this was in common with all countries. By the introduction of the new currency in 1887 the old currency was reduced, the old pound was reduced to 4.27%.

In the same period (1887-1902) Egyptian exports to Great Britain decreased from 63-25 to 52-30, Germany and the United States showing each an increase of over 6%. Exports to Germany had increased from 6-13 to 6-75%, to the United States from 2-06 to 6-07%, and to France from 1-05 to 8-09%. Those to Austria had dropped from 6-30 to 4-00%. From Russia to 9-11 to 8-43%. In 1904 the total value of the exports to Great Britain had increased to £26,121,000, of the exports £28,013,000. Shipping, which before 1900 was nearly 50%, varied from 40 to 45%. No other nation had more than 12% of the tonnage. Italy, France, Russia and Turkey each import from 6% to 12%. The number of ships increased in the five years mentioned from 3 to 7%. In 1905 the number of ships passing through the harbour of Great Britain is first, about 75,000 yearly, or about 3% of all the ships passing from 4,300,000 to 14,000,000. In 1905 the figures were:—Number of ships that passed through the canal, 4116 (2484 being British and 1632 German), net 2,134,156 (83,567 British and 2,134,060 German). Next to British and German are the nations that pass the greatest number of ships by the canal in order of importance is French, Dutch, Austrian, Italian and Russian. About 250,000 passengers (including pilgrims to Mecca) pass through the canal in a year (see further Sub2).

Currency.—The monetary system in force dates from 1885, when existent, nearly all that were coined had been withdrawn from circulation on a sound basis. The system is based on the single gold standard. The unit is a gold coin called a pound and equal to £1, 6s. 8d. in English currency. The Egyptian pound (£E) is divided into 100 piastres, in which there is a gold one and 9 silver 1/20 piastres; one, 1/2 and 1/4 piastres are coined in nickel and 1/6 and 1/12 piastres in bronze. The 1/6 piastre is worth a fraction over 3 pence. The 1/12 piastre is worth 1.4 pence. Of the native population generally reckons in paras. The legal piastre is called the piastre turc (P.T.), to distinguish it from the 1/6 piastre, that is not official usage in Cairo and Alexandria is called a piastre. Officially the 1/6 piastre is called the kantro (k4). A unit of lower denomination, the para being 1/12 of the piastre. The 1/6 piastre has been in circulation generally, now the only foreign coins current are the English sovereign, the French franc, and the Turkish milled gold coin, which is the most popular coin for all the Egyptian gold pieces have been coined. Egyptian silver money is minted at Birmingham, and nickel and bronze money at Vienna. Bank-notes, of the National Bank, are issued for £E100, £E50, £E10, £E1, and for £1 to 20c. The notes are legal tender, but are accepted by the government in payment of taxes.

The history of the currency reform in Egypt is interesting as affording a practical example of a system much discussed in connexion with the currency question in India, namely, a gold standard without a gold coinage. The Egyptian pound is practically non-existent, the only official currency is the pound sterling, and of the par value of 30 shillings. It has been used for years at par with the sovereign, and is in circulation. Their place has been taken by foreign gold, principally the English sovereign, which circulates at a value of 97% piastres. In practice the system works perfectly smoothly, the gold flowing in thither the country through the agency of the National Bank. Bills of exchange circulate, and bills of exchange are thus in circulation. The place of the sovereign has been taken by gold coin, the pound sterling being exchanged on a par with gold coin, and the cubit (of three kinds) 22, 25 and 26 in. The measure of land is the feddan, equal to 1-3 acres, subdivided into 24 birats. The ardeb is equal to about 5 bushels, and is divided into 6 weybas, and each weyba into 24 kget, 1 kget equals 1-12 oz. The rate is:—90 lb, the value 27-5 lb, the kantar (or 100 rolls of 36 oars) 99-04 lb.

Constitution and Administration.—Egypt is a tributary state of the Turkish empire, and is ruled by an hereditary prince with the style of khedive, a Persian title regarded as the equivalent of king. The succession to the throne is by primogeniture.

The central administration is carried on by a council of ministers, appointed by the khedive, one of whom acts as prime minister. To these is added a British financial adviser, who attends all meetings of the council of ministers, but has not a vote; on the other hand, no financial decision may be taken without his consent. The ministers are those of the interior, finance, public works, justice, war, foreign affairs and public instruction, and in each of these are prepared the drafts of decrees, which are sent to the ministry of public instruction was added in 1906 a department of agriculture and technical instruction.
then submitted to the council of ministers for approval, and on being signed by the khedive become law. No important decision, however, has been taken since 1882 without the concurrence of the British minister plenipotentiary. With a few exceptions, laws cannot, owing to the Capitulations, be enforced against foreigners except with the consent of the powers.

While the council of ministers with the khedive forms the legislative authority, there are various representative bodies with strictly limited powers. The legislative council is a consultative body, partly elective, partly nominative. It examines the budget and all proposed administrative laws, but cannot initiate legislation, nor is the government bound to adopt its suggestions. The general assembly consists of the legislative council and the ministers of state, together with popularly elected members, who form a majority of the whole assembly. It has no legislative functions, but no new direct personal tax nor land tax can be imposed without its consent. It must meet at least once in every two years.

For purposes of local government the towns constitute governorships (mooffas), the rest of the country being divided into muhadies or provinces. The governors and muhadies (heads of provinces) are responsible to the ministry of the interior. The provinces are further divided into districts, each of which is under a muhadd, in his turn, supervised by the omda, mayor or head-man, of each village in his district. The governorships are: Cairo; Alexandria, which includes an area of 70 sq. m.; Suez Canal, including Port Said and Ismailia; Suez and El-Arish. Lower Egypt is divided into the provinces of: Behera, Gharbia, Memuha, Dakahlia, Kaliubia, Sharkia. The oasis of Siwa and the country to the Tripolitan frontier are dependent on the province of Behera. Upper Egypt: Giza, Beni Suef, Fayyum, Qina, Assiut, Girga, Kena, Assuan. The peninsula of Sinai is administered by the war office.

Justice.—There are four judicial systems in Egypt: two applicable to Egyptian subjects only, one applicable to foreigners only, and one applicable to foreigners and, to a certain extent, natives also. This multiplicity of tribunals arises from the fact that, owing to the Capitulations, which apply to Egypt as part of the Turkish empire, foreigners are almost entirely exempt from jurisdiction of the native courts. It will be convenient to state first the law as regards foreigners, and secondly the law which concerns Egyptians. Criminal jurisdiction over foreigners is exercised by the consuls of the fifteen powers possessing such right by treaty, according to the law of the country of the offender. These consular courts also judge civil cases between foreigners of the same nationality.

Jurisdiction in civil matters between natives and foreigners and between persons of different nationalities is no longer exercised by the consular courts. The grave abuse to which they have been subject was led to the establishment, in February 1876, at the instance of Nubar Pasha and after eight years of negotiation, of International or "Mixed" Tribunals to supersede consular jurisdiction to the extent indicated. The Mixed Tribunals employ a code based on the Code Napoléon with such additions from Mahomedan law as are applicable. There are two tribunals of first instance, and an appeal court at Alexandria. These courts have both foreign and Egyptian judges—the foreign judges forming the majority of the bench. In certain designated matters they enjoy criminal jurisdiction, including, since 1900, offences against the bankruptcy laws. Cases have to be conducted in Arabic, French, Italian and English, English having been admitted as a "judicial language" by khedivial decree of the 17th of April 1905. Besides their judicial duties, the courts practically exercise legislative functions, as, no important law can be made applicable to Europeans without the consent of the powers, and the powers are mainly guided by the opinions of the judges of the Mixed Courts.

The judicial systems applicable solely to Egyptians are supervised by the ministry of justice, to which has been attached since 1890 a British judicial adviser. Two systems of laws are administered:—(1) the Mekhemels, (2) the Native Tribunals. The mekhemels, or courts of the cadis, judge in all matters of personal status, such as marriage, inheritance and guardianship, and are guided in their decisions by the code of laws founded on the Koran. The grand cadis, who must belong to the sect of the Hanáfsi, sits at Cairo, and is aided by a council of Ulama or learned men. This council consists of the sheik or religious chief of each of the four orthodox sects, the sheik of the mosque of Azhar, who is of the sect of the Shaf'í, the chief (wahib) of the Shafkí, or descendants of Mahomet, and others. The cadis are chosen from among the students at the Azhar university. In the same manner, in matters of personal law, Copts and other non-Moslem Egyptians are, in general, subject to the jurisdiction of their own religious chiefs.

For other than the purposes indicated, the native judicial system, both civil and criminal, was superseded in 1884 by tribunals administering a jurisprudence modelled on that of the French code. It is, in the words of Lord Cromer, "in many respects ill adapted to meet the special needs of the country" (Egypt, No. 1, 1904, p. 33). The system was, on the advice of an Anglo-Indian official (Sir John Scott), modified and simplified in 1891, but its essential character remained unaltered. In 1904, however, more important modifications were introduced. Save on points of law, the right of appeal in criminal cases was abolished, and assize courts, whose judgments were final, established. At the same time the penal code was thoroughly revised and the Egyptian judges were "the first time provided with a sound working code" (Ibid. p. 49). The native courts have both native and foreign judges. There are courts of summary jurisdiction presided over by one judge, central tribunals (or courts of first instance) with three judges, and a court of appeal at Cairo. A committee of judicial surveillance watches the working of the courts of first instance and the summary courts, and endeavours, by letters and discussions, to maintain purity and sound law. There is a procureur-general, who, with other duties, is entrusted with criminal prosecutions. His representatives are attached to each tribunal, and form the parquet under whose orders the police act in bringing criminals to justice. In the markak district tribunals, created in 1904 and presided over by magistrates with jurisdiction in cases of misdemeanour, the prosecution is, however, conducted directly by the police. Special Children's Courts have been established for the trial of juvenile offenders.

The police service, which has been subject to frequent modification, was in 1895 put under the orders of the ministry of the interior, to which a British adviser and British inspectors are attached. The provincial police is under the direction of the local authorities, the muhadies or governors of provinces, and the masurs or district officials; to the omdas, or village head-men, who are responsible for the good order of the villages, a limited criminal jurisdiction has been entrusted.

Religion.—The great majority of the inhabitants are Mahomedans. In 1907 the Moslems numbered over ten millions, or 91.8% of the entire population. The Christians in the same year numbered 880,000, or 8% of the population. Of these the Coptic Orthodox church had some 667,000 adherents. Among other churches represented were the Greek Orthodox, the Armenian, Syrian and Maronite, the Roman Catholic and various Protestant bodies. The last-named numbered 37,000 (including 24,000 Copts). There were in 1907 over 38,000 Jews in Egypt.

The Mahomedans are Sunnites, professing the creed commonly termed "orthodox," and are principally of the persuasion of the Shafí, whose celebrated founder, the imam ash-Shafi', is buried in the great southern cemetery of Cairo. Many of them are, however, Hanáfsi (to which persuasion the Turks chiefly belong), and in parts of Lower, and almost universally in Upper Egypt, Múalik. Among the Moslems the sheikh al-Islam, appointed by the khedive from among the ulama (learned class), exercises the highest religious and, in certain subjects, judicial authority. There is also a grand cadi, nominated by the sultan of Turkey from among the ulama of Stamboul. Valuable property is held by the Moslems in trust for the promotion of religion and for charitable purposes, and is known as the Wakfs administration. The revenue derived is over £250,000 yearly.

The Coptic organization includes in Egypt three metropolitan
and twelve bishops, under the headship of the patriarch of Alexandria. The minor orders are arch-priests, priests, arch-deacons, deacons, readers and monks (see Corps: Coptic Church).

Education.—Two different systems of education exist, one conducted on native lines, the other European in character. Both systems are more or less fully controlled by the ministry of public instruction. The government has primary, secondary and technical schools, training colleges for teachers, and schools of agriculture, engineering, law, medicine and veterinary science.

The government system, which dates back to a period before the British occupation, is designed to provide, in the main, a European education. In the primary schools Arabic is the medium of instruction, the use of English for that purpose, being confined to lessons in that language itself. The school of law is divided into English and French sections according to the language in which the students study law. Besides the government primary and secondary schools, there are many other schools in the large towns conducted by the Moslems, Copts, Hebrews, and by various missionary societies, and in which the education is on the same lines. A movement initiated among the leading Moslems led in 1908 to the establishment as a private enterprise, of a school devoted to scientific, literary and philosophical studies. Political and religious subjects are excluded from the curriculum and no discrimination in regard to race or religion is allowed.

Education on native lines is given in kuttab and in the Asrar minbar. A kuttab is a school attached to mosques, founded in every village and in every quarter of the larger towns. In these schools instruction given before the British occupation was very slight. All pupils were taught to recite portions of the Koran, and a proportion of the pupils could read and write Arabic, and a little simple arithmetic. Those pupils who succeeded in committing to memory the whole of the Koran were regarded as hik (learned in the Coptic language), and such escaped liability to military conscription. The government has improved the education given in the kuttabs, and numbers of them have been taken under the observance of the ministry of public instruction. In such schools an excellent elementary secular education is given, in addition to the instruction in the Koran, to which half the school hours are devoted. The number of pupils in 1905 was over 12,000 boys and 2000 girls. Granta-in-aid are given to other schools where a sufficiently good standard of instruction is maintained. No grant is made to any kuttab where any language other than Arabic is taught. In all there are over 10,000 kuttabs, attended by some 250,000 scholars. The number of pupils in private schools under government inspection was in 1898, the first year of the grant-in-aid system, 7535; in 1905, 13,315; in 1908, 14,562; and in 1911, 16,740. A grant from the government was given in 1903. The number of pupils in 1903 was 977 in 1900 and 6611 in 1905. The Copts have about 1000 primary schools, in which the teaching of Coptic is compulsory, a few industrial schools, and one college for higher instruction.

Cairo holds a prominent place as a seat of Moslem learning, and its university, the Ashtar, is considered the first of the eastern world. It comprises 3 faculties, namely: Law, Logic, and Syntax and Syriac, and 2 departments, one being a theological school, and the other a medical school. The students come from all parts of the Mahommedan world. They number about 8000, of whom some 2000 are resident. The students pay fees, and the professors receive no salaries. The latter maintain themselves by private teaching and by copying manuscripts, and the former in the same manner, or by reciting the Koran. To meet the demand for better qualified teachers for the Moslem courts a college was established in 1807, known as the "bahr" or "ocean", by which the subjects taught at the Ashtar university, instruction is given in literature, mathematics and physical science. The necessity for a rational development of the Arab system itself being also recognized by the high Moslem dignitaries in Egypt, a law was passed in 1907 creating a superior board of control under the presidency of the Sheik of the Copts, to take charge of the new system of schools and other similar establishments. This attempt to reform the Ashtar met, however, with so much opposition that in 1909 it was, for the time, abandoned.

In 1897, the sedentary Egyptian population over seven years of age, some 12% of the Moslems could read and write, female literacy having increased 30% since 1897; of the foreign population over seven years of age 75% could read and write. Of the Coptic community about 50% can read and write.

Literature and the Press.—Since the British occupation there has been a marked renaissance of Arabic learning and literature in Egypt. Societies formed for the popularization of the Coptic and Arabic literature have brought to light important texts bearing on Mahommedan history, antiquities and religion. Numbers of magazines and journals are published, which deal with ethnology and the advancement of learning. Side by side with these literary organs there exists a vernacular press largely devoted to nationalist propaganda. Prominent among these papers are Al-Ahram (The Standard), Al-Ahram (The Standard) and Al-Usrah. A similar character are Al-Mu'assasa, Al Mu'mad and Al-Gerda. The Mokatatam represents the views of the more enlightened and condescending aspect of the Egyptian press. Of French newspapers, there are also published several newspapers in English and French.

Authorities.—(a) General descriptions, geography, travel, &c.: Description de l'Egypte (1809-1822), compiled by the scientific commission sent to Egypt by Bonaparte; Clot Bey, Apéréo général sur l'Egypte, 2 vols. (Paris, 1840); Boisnet Bey, Dictionnaire géographique de l'Egypte ( Cairo), 2 vols., London, 1843; Lady Duff Gordon, Letters from Egypt, complete edition (London, 1902), an invaluable account of social conditions; (b) 1813-1818; A. B. Edwards, A Thousand Miles through Egypt and the Nile (2nd ed., London, 1865); Sale (2nd ed., London, 1869); Fellows and Explorers (London, 1882); H. W. Mardon, Geography of Egypt, London, 1902, an excellent elementary text-book; (c) 1830-1850; South, The Nile and Her Delta; The Nile and the Delta, with suggestive chapters on: S. Lane Poole, Egypt (London, 1881); A. B. de Duqueville, New Egypt, translated from the French (London, 1851); T. Kelly, Egypt (London, 1853); T. Kelly and B. Williams, Egypt (London, 1856); The best maps are those of the Survey Department, Cairo, on the scale of 1: 40000 (1:3 in. to the mile).

Administration.—Sir John Bowring's Report on Egypt (1835) to Lord Clarendon (1840) show the conditions of the country in the period. For the study of the state of Egypt at the time of the British occupation, 1882, and the development of the country since, the most valuable of all documents is the Official Reports of the British Government on the trade of Egypt and of Alexandria and of the tonnage and shipping of the Suez Canal are also issued yearly.

I. Official.—The Reports on the Finances, Administration and Condition of Egypt, issued yearly since 1852 (the reports 1851-1881 are entirely financially, and those of 1882-1891, those of 1892-1900, those of 1882-1903, those of 1892-1895, those of 1892-1895; Despatch from Lord Dufferin forwarding the decree constituting the new Public Institutions of Egypt (1893); Reports on the State of Egypt and the Progress of Administrative Reforms (1885); Reports by Sir H. D. Wolff on the Administration of Egypt (1887), Annual reports are published in Cairo in English by the various departments, and by the British government missions on the trade of Egypt and of Alexandria and of the tonnage and shipping of the Suez Canal are also issued yearly.

II. Miscellaneous.—Law: Sir J. Monk and G. R. Masefield, A Digest of the laws in force in Egypt (2 vols., 1908), an authoritative record; Alfred (Lord) Milner, England in Egypt, first published in 1892, the story being brought up to 1904 in the 11th edition, 1911; Sir A. Colville (Lord), Egypt, 1911; Sir H. Ward, Pyramids and Progress (1900); A. S. White, The Expansion of Egypt (1890); and F. W. Fuller, Egypt and the Hinterland (1901). See also the works cited in History, last section.

The diplomatic relations of the Egyptians at Paris are treated in France (1867); J. Scott, The Law affecting Foreigners in Egypt (Edinburgh, 1897); The Egyptian Cables (London, 1892).

(d) Irrigation, agriculture, geology, &c.;: Despatch from Sir Evelyn Baring enclosing Report on the Condition of the Agricultural Population in Egypt (1888); Notes on Egyptian Crops (Cairo, 1896); Jacob Artin Bey, La Propriété fonciere en Egypte (Bulaq, 1885); Report on Perennial Irrigation and Flood Protection for Egypt, 1 vol. and atlas (Cairo, 1894). The reports (Egypt, No. 2, 1901, and Egypt, No. 2, 1903, are of Sir William MacMunn's report on irrigation in Egypt and are very valuable records—notably the 1904 report. W. Willcocks, Egyptian Irrigation (2nd ed., 1899); H. G. Lyons, The Actual and Potential Sources of the River Nile, with an Account of the River's Character and an Study of the Influence of the River on the Geology and Agriculture of Egypt (1897). Annual meteorological reports are issued by the Public Works Department, Cairo. The department is divided into the sections of topography, agriculture, and general duties. For the study of the Nile, records of the observations are kept, and daily and monthly average temperatures and rainfall are recorded. Several maps of the Nile are in the possession of the government, and a new one, the Nile Survey Map, is in process of preparation. G. E. Shelley, Birds of Egypt (London, 1872).

1 The place of publication is London unless otherwise stated.
Inhabitants.

The population enumerated at the census taken in April 1897 was 11,890,978. In these figures nomad Arabs or Bedouins, estimated to number 97,831, are not included. The total population was thus returned at 11,987,359, or some 16% more than in 1897 when the inhabitants numbered 9,734,495. The figures for 1897 compared with 6,831,919 in 1882, an increase of 43.5% in fifteen years. Thus, during the first twenty-five years of the British occupation of the country the population increased by 4,056,000. In 1897 the French estimated the population at 2,446,000; the census figures give the average annual increase was 1.2%. If the desert regions be excluded, the population of Egypt is extremely dense, being about 939 per sq. m. This figure may be compared with that of Belgium, the most densely populated country in Europe, 589 per sq. m., and with that of Bengal, 586 per sq. m. In parts of Menaia, a Delta province, the density rises to 1322 per sq. m., and in the Kena province of Upper Egypt to 1528.

The population is generally divisible into—

1. The Fellahin or peasants and the native townsmen.
2. The Bedouins or nomad Arabs of the desert.
3. The Nubians, or the inhabitants of the Nile valley between Assuan and Dongola.
4. Foreigners.

The first of these divisions includes both the Moslem and Coptic inhabitants. The Bedouins, or the Arabs of the desert, are of two different classes: first, Arabic-speaking tribes who range the deserts as far south as the N.; secondly, the tribes inhabiting the desert from Kossir to Suakin, namely the Haddaanaa, Bisharin and the Ababa tribes. This group speak a language of their own, and are probably descendants of the Blemmyes, who occupied these parts in ancient times (see Arabs; Bedouins; HADODA; BISHARIN; &c.). The Nubas are of mixed negro and Arab blood. They are mainly agriculturists, though some are keen traders (see NUBIA).

Foreigners number over 75,000, and form 1.3% of the total population. They are chiefly Greeks—of whom the majority live in Alexandria—Italians, British and French. Syrians and Levantines are numerous, and there is a colony of Persians. The Turkish element is not numerically strong—a few thousands only—but holds a high social position.

Of the total population, about 20% is urban. In addition to the 97,000 pure nomads, there are half a million Bedouins described as "semi-sedentary," i.e. tent-dwelling Arabs, usually encamped in those parts of the desert adjoining the cultivated land. The rural classes are mainly engaged in agriculture, which occupies over 62% of the adults. The professional and trading classes form about 10% of the whole population, but 50% of the foreigners are engaged in trade. Of the total population the males exceed the females by some 46,000.

The Coptic inhabitants are described in the article CORPS, and the rural population under FALLAH. It remains here to describe characteristic and customs common to the Moslem Egyptians and particularly to those of the cities. In some respects the manner of life of the natives has been modified by contact with Europeans, and what follows depicts in general the habits of the people where little affected by western culture. With regard to physical characteristics the Egyptians are of full average height (the men are mostly 5 ft. 8 in. or 5 ft. 9 in.), and both sexes are remarkably well proportioned and of strong physique. The Cairoese and the inhabitants of Lower Egypt generally have a clear complexion and soft skin of a light yellowish colour; those of Middle Egypt have a tawny skin, and the dwellers in Upper Egypt a deep bronze or brown complexion. The face of the men is of a fine oval, forehead prominent but seldom high, strong nose, deep set eyes, and big ear. The women, when well dressed, are variously and richly adorned. In many she is very well built, with rather full lips, regular teeth beautifully made, and beard usually black and curly but scanty. Moustaches are worn, while the head is shaved save for a small tuft (called shebakh) upon the crown. As to the women, "from the age of fourteen to that of eighteen or twenty, they are generally models of beauty in body and limbs; and in countenance most of them are pleasing, and the majority are very lovely; but, when they have attained their perfect growth, they rapidly decline." There are few Egyptian women over forty who retain either good looks or good figures. "The forms of womanhood begin to develop themselves about the ninth and tenth year: at the age of fifteen or sixteen they generally attain their highest degree of perfection; their lips and eyes are then the most beautiful, and the expression—eyes more beautiful can hardly be conceived: their charming effect is much heightened by the concealing of the other features and the blackening of the eyebrows and eyelids above and below the eye, with a black powder called 'kohl'" (L keeper, Modern Egyptians). Both sexes, but especially the women, tattoo several parts of the person, and the women stain their hands and feet with a red dye of the same kind.

The dress of the men of the upper and middle classes who have not adopted European clothing—a practice increasing commonly—very wide sleeves. Above these are generally worn a waistcoat without sleeves, and a long vest of silk, called kafan, which has hanging sleeves, and reaches nearly to the ankles. The kafan is confined by a belt, and is secured at the back with a silk scarf or other woolen shawl. Over all is worn a long cloth robe, the gibbeh (or jibbah) somewhat resembling the kafan in shape, but hanging longer in front, is flapped back, and leaves the lower orders is the shirt and drawers, and waistcoat, with an outer shirt of blue cotton or brown woolen stuff; some wear a kafan. The women are usually dressed in a tunic or tarsand, and a veil of the same material. The turban is usually worn. Men who have otherwise adopted European costume retain the turbash. Many ladies and professions, &c., are distinguished by the shape and colour of the turban, and various styles of turban are worn, with different colourings of their robes; but the poor go usually barefoot. Many ladies of the upper classes now dress in European style, with certain modifications, but retain the veil and the turban. Girls usually wear a full pair of silk trousers, bright coloured stockings (usually pink), and a close-fitting vest with hanging sleeves and skirts, open down the front and at the sides, and long enough to turn up and fasten under the armpits, which is inscribed with a case, with a narrow belt of richly embroidered with gold, and having short sleeves, is commonly worn over the vest. The hair in front is combed down over the forehead and across in a straight line; behind it is left long, with many small plaits, which hang down the back, and are lengthened by silken cords, and often adorned with gold coins and ornaments. A small turbash is worn on the back of the head, sometimes having a plate of gold fixed on the crown, and a handkerchief is tastefully bound round the temples. The women of the lower orders have trousers of printed or dyed cotton, and a close waistcoat. All wear the long and elegant head-dress. This is a simple 'breath' of muslin, which passes over the head and hangs down behind, one side, being drawn forward over the face in the presence of a man. A lady's dress is of white muslin, which is fastened at the neck by a brooch, and is held by a rope, that of a person of the lower class is simply dyed blue. In going abroad the ladies wear above their indoor dress a loose robe of silk without sleeves and nearly openly fastened, with a large, deep, dark blue turban, with a great portion of their hair hanging down the back. The men generally wear a wide turban, and have a large hat. The women wear a cap or turban of black silk, which is brought over the head, and gathered round the person by the arms and hands on each side. A face-veil entirely conceals the features, except the eyes; it is a long and narrow piece of thick white muslin, reaching to a little below the knees. The women of the lower orders have the same out-door dress of different materials and colour. Ladies use slippers of yellow morocco, and abode, inner boots of the same material, above which they wear, in either case, thick shoes, having only toes. The poor wear red shoes, very like those of the men. The women, especially in Upper Egypt, not infrequently wear nose-rings. This, though often neglected, is a mark of treatment, and reverence for their parents and the aged is early inculcated. They are also well grounded in the leading doctrines of Islam. Boys are clothed in white, the girls in black clothes. All children go to school generally with a Bridal procession, on a gayly caparisoned horse and dressed in woman's clothes. Most parents send their boys to school when they know of no other way to teach them to read. In the 19th century a great desire for the education of girls has arisen (see Education).

The wedding ceremony is very simple. The marriage is regarded as a permanent contract, and the bride is considered married if she is spoken for by a man. The marriage is performed by a fik (a schoolmaster, or one who recites the Koran, properly one learned in Fikh, Mahomedian law) in the presence of two witnesses. The bridal of a virgin is attended with great festivity and rejoicing, and a grander's
wedding sometimes continuing eleven days and nights. On the last
day, which should be that terminating with the eve of
Monday, the bride is taken in procession to the bridegroom's house,
accompanied by her female friends, and a band of musicians, jugglers,
wrestlers, &c. As before stated, a boy about to be circumcised joins
the procession, provided he is frequently, a successor, or a brother-
boys. Though allowed by his religious four wives, most Egyptians are
monogamists. A man may, however, possess any number of con-
cubines, dependent on the quality of the laws regulating marriage with
by her in consideration of her superior position and power over them,
a power which she often uses with great tyranny; but certain powers
are reserved to their filial piety, especially if their aged parents res-
side to their master. A divorce is rendered obligatory by the simple
words "Thou art divorced." Repudiation may take place twice
without being final, but if the husband repeats thrice "Thou art
divorced" it is considered absolute. In that case the dowry must be
returned to the wife.

Elaborate ceremonies are observed at funerals. Immediately
on death the corpse, assisted by hired mourners, commence their peculiar
wailing, while fikis recite portions of the Koran. The funeral takes
place on the day of the death; if they stay the night, otherwise
the next day. The corpse, having been washed and shrouded,
is placed in an open bier, covered with a cashmere shawl, in the case
of a man; or in a closed bier, having a post in front, on which are
placed the ordinary prayers, in that way, of a drunkard. The funeral
procession is headed by a number of people, and generally blind, men,
chanting the profession of the faith, followed by male friends of the
deceased. The music of sheikhs is occasionally heard; chanting, prose,
and a poem descriptive of the state of the soul after death. Then follows
the bier, borne on the shoulders of friends, who are relieved by the
passers-by; a music being played by the women and girls of the
family. On their approach to the grave site, they sing a simple song;
thereafter the mourning is performed on the grave, and the corpse is
then buried in the cemetery. The corpse is generally carried in a casket
burial service is performed by the imam, and the pro-
cession is continued to the tomb. There the women and girls sing,
and bread and distribution are distributed to the poor at the grave; and sometimes
a buffalo or several buffalo are slaughtered there, and the flesh given to the poor. In some cases this is a vain custom,
believed to remain with the body that one night, fikis are engaged
at the house of the deceased to recite various portions of the Koran,
and songs. Music in Egypt is a very real fact, the profession of
the faith, "There is no God but God," three thousand times.
The women alone put on mourning attire, by dyes their veils, shawls,
&c., dark blue, with indigo; and they stain their hands, and smear
the walls, with the same colour. The mourners are also
turned upside down. The latter customs are not, however, observed
on the death of an old man. At certain periods after the burial, a
kitchen, or recitation of the Koran, is performed at the tomb, and the visit is by the women and relations and friends of the
deceased. The women of the peasants of Upper Egypt perform
stately mourning processions, and many of the religious festivals, and
which are regarded partly as relics of ancient Egyptian customs.

The harem system of appointing separate apartments to the
women, and excluding them from the gaze of men, is observed in Egypt,
and is considered necessary to the religion and the customs of
the Egyptians. In many a modern household, in which the customs
of an Egyptian household in which old customs are maintained never
sit in the presence of the master, but attend him at his meals, and
are treated in every respect as inferiors. The mother, however,
forms a remarkable exception to this rule; in rare instances, also,
a wife becomes a companion to her husband. On the other hand,
if a pair of women's shoes are placed outside the door of the harem
apartments, they are understood to signify that female visitors are
within, and a man is sometimes thus excluded from the upper
portion of his own house for many days. Ladies of the upper or
middle classes lead a life of extreme inactivity, spending much
at the bath, which is the general place of gossip, or in receiving visits,
embroidering, and the like, and in absolute dolce far niente.
Both sexes are very ceremonious.
The principal meals are breakfast, about an hour after sunrise,
dinner, or the mid-day meal, at noon; and supper, which is
the chief meal of the day, a little after sunset. Pastry, sweetmeats,
fruit, and coffee are taken at all hours, and is, with
a pipe, presented at least once to each guest. Tobacco is the great
luxury of the men of all classes in Egypt, who begin and end the day
with a smoke. The men of all classes love all day long, and the interiors of houses are decorated with all kinds of objects,
and the gradual display of gorgeous drapery for the retainers of
the officers of state. A regiment of regular infantry makes but a sorry
sight of its color in the form of a horseman, who, instead of
of the Prophet (Mold en-Nebi), which is celebrated in the beginning
of the third month, is the greatest festival of the whole year.

For nine days and nights Cairo has more the aspect of a fair than
a city, a grand bazaar, whose shops are crowded with
bazaar, and the stalls of dervishes are crowded with all kinds of
in some large open spot round which are erected the tents of
the khevides, of great state officials, and of the dervishes. Next in
time, and also in importance, is the Mold El-Hassan, commemorative
of the birth of Hosain, and lasting fifteen days and nights; and at the same time is kept the Mould of al-Safi' Ayyub, the last sovereign but one of the Ayyubite dynasty. In the seventh month occur the Mould of the sayyida Zenab, and the commemoration of the Mirag, or the Prophet's miraculous journey to heaven. Early in the eighth month (Sha'bân), the Mould of the imam Shâhî is observed, followed by the fast of the middle of that month held by the Moslems, customs, being held by the Moslems to be that on which the fate of all living is decided for the ensuing year. Then follows Ramadân, the month of fasting, a severe business. Early in the seventh month, the Lesser Festival (al-id as-saghir), which commences Shawwâl, is hailed by them with delight. A few days after, the Kiswa, or new covering for the Ka'âba at Mecca, is taken in procession from the city gates, always accompanied by the muezzin. The high priest of the Haram is then led to the Ka'âba, and the Mould of the imam Shâhî is brought to the city gates, called the Al'îd-al-kabîr, or that of the Sacrifice (commemorating the willingness of Ibrahim to slay his son Ismail—according to the Arab legend), closures of the Lasses and Great Festivals are those known in Turkish as the Bairâm (q.v.).

The rise of the Nile is naturally the occasion of annual customs, some of which are doubtless relics of antiquity; these are observed according to the Calendar: The first of them attains its greatest height, the month being commemoatated on the night of the 11th of Ba'dha, the 17th of June, called that of the Drop (lelet-ên-Nuitka), because a miraculous drop is believed to fall on the swelling of the Nile. The real rise begins at Cairo about the summer solstice, or a few days later, and early in July a crier in each district of the city begins to go his daily rounds, announcing, in a quaint chant, the increase of the water. The cornice of the Fâtâr Dîkâr of the city has risen 20 or 21 ft., he proclaims the Wefâ en-Nil, "Compeletion," or "Abundance of the Nile." On the following day the dam which crowns the nile is opened, and a great ceremony has been made, the ceremony having been filled up in 1897 the ceremony has been much modified, but a brief description of what used to take place may be given. A pillar of the dam is called the "Bride of the Nile." The Arab historians relate that this was substituted, at the Moslem conquest, for a virgin whom it was the custom annually to sacrifice, to ensure a plentiful inundation. A large boat, gaily decked out, representing what was believed to be the holy fish, was anchored near, and a gun on board fired every quarter of an hour during the night. Rockets and other fireworks were also let off, but not with much effect, as they would very quickly burst, after daybreak. The governor attended the ceremony, with the cadi and others, and gave the signal for the cutting of the dam. As soon as sufficient water had entered the boat ascended the canal to the city. The crier continues his daily rounds, with his former chant, excepting on the Coptic New Year's Day, when the cry of the Wefâ is repeated, until the Saib, or Discovery of the Cross, the 26th or 27th of September, at which hour the last rain is also much revered, and his festival, together, in like manner, great crowds to its birthplace, the town of Desh. But, besides the graves of her native saints, Egypt boasts of those of the members of the sultan's family, the tomb of the sayyida Zeyneb, daughter of 'Ali, that of the sayyida Sekeina, daughter of Hosain, and that of the sayyida Nefas, great-grand-daughter of Hasan, all of which are held in high veneration. The mount of (or that of the two Hasans, the most revered shrine in the country, and is believed to contain the head of Hosain. Many orders of Dervishes live in Egypt, the following are the most celebrated: (1) the Rif'ût, which seits the Iwâiani and Saadia; (2) the Qâdiri (Kahiriya), or bowing dervishes; (3) the Ahmedia, or followers of the sayyida Abû Adbâd, and their sects the Beydima (known by their long hair), Sha'riâwa, Sha'riâna and many others; and (4) the Shrâfiz or followers of the sayyida Irhâm Ed-Deskii. These are all presided over by a direct descendant of the caliph Abu Bekr, called the Shu'ab, and the Saadia are famous for charming live serpents, etc., and the Iwâiani for eating fire, glass, etc. The Egyptians firmly believe in the efficacy of charms, a belief associated with that in an omnipresent and over-ruling providence. Thus the doors of houses are inscribed with sentences from the Koran, or the like, to preserve from the evil eye, or avert the dangers of an unlucky threshold; similar inscriptions may be observed over most shops, while almost every one carries some charm about his person. The so-called sciences of magic, astrology and alchemy still flourish. The British Military Mission to Egypt is E. W. Lane's Manners and Customs of the Modern Egyptians, first published in 1836. The best edition is that of 1860, edited, with additions, by Sir B. Proctor. See also S. Jeane, Fakir Life in Egypt (2 vols., 1852); S. Lane Poole, Social Life in Egypt (1884); P. Arminjon, L'Enseignement, la doctrine, et la vie dans les universités musulmanes d'Egypte (Paris, 1890). For the language see J. S. Millmore, The Modern Arabic of Egypt (2nd ed., London, 1905); Spitta Bey, Grammatik des arabischen Vulgärdialektes von Ägypten, Contes arabes modernes (Leiden, 1883). For statistical information concerning the republic of 1875, a report was published by the Ministry of the Interior, Cairo, in 1876 and 1890.

Finance.

The important part which the financial arrangements have played in the political and social history of Egypt since the accession of Ismail Pasha in 1863 is shown in the section History of this article. Here it is proposed to trace the steps by which Egypt, after having been brought to a state of bankruptcy, passed through a period of great stress, and finally attained prosperity and a large measure of financial autonomy.

In 1882 the foreign debt of Egypt stood at £5,452,000. With the accession of Ismail Pasha, a period of wild extravagance and reckless borrowing accompanied by the extortion of every piastre possible from thefellahin. The real state of affairs was disclosed in the report of Mr Stephen Cave, a well-known banker, who was sent by the British government in December 1875 to inquire into the situation. The Cave report showed that Egypt suffered from "the ignorance, dishonesty, waste and extravagance of the East," and from "the want expense caused by hasty and incomconsiderate endeavours to adopt the civilization of the West." The debtor and creditor account of the state from 1864 to 1875 showed receipts amounting to £14,215,000. Of this sum over £94,000,000 had been obtained from revenue and nearly £4,000,000 by the sale of the khedive's shares in the Suez Canal to Great Britain. The rest was credited to: loans £31,713,000, floating debt £18,245,000. The cash which reached the Egyptian treasury from the loans and floating debt was far less than the nominal amount of such loans, none of which cost the Egyptian government less than 12% per annum. When the expenditure during the same period was examined the extraordinary fact was disclosed that the surplus of revenue was only three millions less than that spent on administration, tribute and public works, including a sum of £10,500,000, described as "expenses of questionable utility or policy." The whole proceeds of the loans and floating debt were absorbed in paying off interest, debentures, etc., with the exception of £16,000,000 debited to the Suez Canal. In other words, Egypt was burdened with a debt of £51,000,000—funded or floating—for which she had no return, for even from the Suez Canal she derived no revenue, owing to the sale of the khedive's shares.

Soon after Mr Cave's report appeared (March 1876), default took place on several of the loans. Nearly the whole of the debt, it should be stated, was held in England or France, and at the instance of French financiers the stoppage of payment was followed by a scheme to unify the debt. This scheme included the distribution of a bonus of 25% to holders of treasury bonds. These bonds had then reached a sum exceeding £20,000,000 and were held chiefly by French firms. The unification scheme was elaborated in a khedival decree of the 7th of May 1876, but was rendered abortive by the opposition of the British Government. Its place was taken in 1877 by the Law of 1876 (St. L. P.), which provided that all debts should be paid up by Mr (afterwards Lord) Osochen and M. Joubert, who represented the British and French bondholders respectively. The details of this settlement, promulgated by decree of the 17th of November 1876, need not be given, as it was superseded in 1880. One of the securities devised for the benefit of the bondholders in the abortive scheme of May 1876 was retained in the
Goschen-Joubert settlement, and being continued in later settlements grew to be one of the most important institutions in Egypt. This security was the establishment of a Treasury of the Public Debt, known by its French title of Caisse de la Dette, and commonly spoken of simply as "the Caisse." The duty of the Caisse was to act as a custodian of the revenue and expenditure—the "Dual Control," while a commission was appointed in 1878 to investigate the condition of the country. The settlement of 1882 was effected on the basis of the proposals made by this commission, and was embodied in the Law of Liquidation of July 1880—a few years after the deposition of Ismail. For the purposes of the new settlement, the loans raised by Ismail on his private estates, those known as the Dafra (i.e. "on administrations") and Domains loans, were brought into account. By the Law of Liquidation the floating debt was paid off, the whole debt being consolidated into four large loans, upon which the rate of interest was reduced to a figure which it was considered Egypt was able to bear. The Egyptian debt under this composition was:

- Privileged debt: £2,500,000
- Unified debt: £8,018,000
- Dafra Saiouch loan: £6,313,000
- Domains loan: £3,500,000

Total: £28,640,000

The rate of interest was, on the Privileged debt and Domains loan, 5%; on the Unified debt and Dafra loan, 4%. Under this settlement the total annual charges on the country amounted to £4,500,000, about half the then revenue of Egypt. These charges included the services of the Privileged and Unified debts, the tribute to Turkey and the interest on the Suez Canal shares held by Great Britain, but excluded the interest on the Dafra and Domains loans, expected to be defrayed by the revenues from the estates on which those loans were secured. The general revenue of Egypt was divided between the bondholders and the government, any surplus on the bondholders' share being devoted to the redemption of the capital.

The 1880 settlement proved little more lasting than that of 1876. After a brief period of prosperity, the Arabi rising, the riots at Alexandria, and the events generally which led to the British occupation of Egypt in 1882, followed by the losses incurred in the Sudan in the effort to prevent it falling into the hands of the Mahdi, brought Egypt once more to the verge of financial disaster. The situation was an anomalous one. While the revenue assigned to the service of the debt was more than sufficient for the payment of interest and the sinking fund was in full operation, the government found that their share of the revenue was altogether inadequate for the expenses of administration, and they were compelled to borrow on short loans at a high rate of interest. Moreover, to make good the losses incurred at Alexandria, and to get money to pay the charges arising out of the Sudan War and the Arabi rebellion, a new loan was essential. On the initiative of Great Britain a conference between the representatives of the great powers and Turkey was held in London, and resulted in the signing of a convention in March 1889. The terms agreed upon in this instrument, known as the London Convention, were embodied in a decree, which, with some modification in detail, remained for twenty years the organic law under which the finances of Egypt were administered.

The principle of dividing the revenue of the country between the Caisse, as representing the bondholders, and the government was maintained by the London Convention. The revenue assigned to the service of the debt, namely, that derived from the railway, telegraphs, port of Alexandria, customs (including tobacco) and from four of the provinces, remained as before. It was recognized, however, that the non-assigned revenue was insufficient to meet the necessary expenses of government, and a scale of administrative expenditure was accordingly drawn up. This was originally fixed at £5,237,000, and was subsequently other charge. This was again increased, and in 1894, in the last year in which the system described existed, it was £6,300,000. The Caisse was authorized, by payment of the coupons on the debt, to make good out of their balance in hand the difference between the authorized expenditure and the non-assigned revenue. If a surplus remained to the Caisse after making good such deficit the surplus was to be divided equally between the Caisse and the government; the government to be free to spend its share as it pleased, while the Caisse had to devote its share to the reduction of the debt. This limitation of administrative expenditure was the cardinal feature and the leading defect of the convention. Those responsible for this arrangement—the most favourable for Egypt that Great Britain could secure—failed to recognize the complete change likely to result from the British occupation of Egypt, and probably regarded that occupation as temporary. The system devised might have been justifiable as a check on a retrograde government, but was wholly inapplicable to a reforming government and a serious obstacle to the attainment of national prosperity. In practice administrative expenditure always exceeded the amount fixed by the convention. Any excess could, however, only be met out of the half-share of the eventual surplus reached in the manner described. Consequently, in order to meet new expenditure necessitated by the growing wants of a country in process of development, just double the amount of revenue had to be raised.

To return to the provisions of the London Convention. The convention left the permanent rate of interest on the debt, as fixed by the Law of Liquidation, unchanged, but to afford temporary relief to the Egyptian exchequer a reduction of 5% on the interest of the debt was granted for two years, on condition that if at the end of that period payment, including the arrears of the two years, was not resumed in full, another international commission was to be appointed to examine into the whole financial situation. Lastly, the convention empowered Egypt to raise a loan of nine millions, guaranteed by all the powers, at a rate of interest of 3%. For the service of this loan—known as the Guaranteed loan—an annuity of £315,000 was provided in the Egyptian budget for interest and sinking fund. The £5,000,000 was sufficient to pay the Alexandria indemnities, to wipe out the deficits of the preceding years, to give the Egyptian Treasury a working balance of £1,000,000 and thereby avoid the creation of a fresh floating debt, and to provide a million for new irrigation works. To the wise foresight which, at a moment when the country was sinking beneath a weight of debt, did not hesitate to add this million for expenditure on productive works, the present prosperity of Egypt is largely due.

The provisions of the London Convention did not exhaust the restrictions placed upon the Egyptian government in respect of financial autonomy. These restrictions were of two categories, (1) those independent of the London Convention, (2) those dependent upon that instrument. In the first category came (a) the prohibition to raise a loan without the consent of the Porte. The right to raise loans had been granted to the khedive Ismail in 1873, but was taken away in 1879 by the firman appointing Tewfik khedive. (b) Next came the inability to levy taxes on foreigners without the consent of their respective governments. This last obligation was, in virtue of the capitulations, applicable to Egypt as part of the Ottoman empire. The other regulation, resulting from the Ottoman law under which foreigners are allowed to acquire and hold real property, is the land tax. (All taxes formerly paid by natives and not by foreigners have been abolished in Egypt, but the immunity described constitutes a most serious obstacle to the redistribution of the burden of taxation in a more equitable manner.)

1 Figures of the debt are always given in £ sterling. The budget figures are in £E. (pounds Egyptian), equal to £1, os. 6d.
From the purely Egyptian point of view the most powerful restriction in this first category remains to be named. In 1853 the necessity of obtaining over the commodity by French and British controllers was replaced by that of a British official called the financial adviser. The British government has declared that "no financial decision shall be taken without his consent," a declaration never questioned by the Egyptian government. This restriction, therefore, is at the same time the chief safeguard for the purity of Egypt's finances.

In the second category of restrictions, namely, those dependent on the London Convention, were the various commissions or boards known as Mixed Administrations and having relations of a quasi-independent character with the ministry of finance. Of these boards by far the most important was the Caisse. As first constituted it consisted of a French, an Austrian, and an Italian member; a British member was added in 1877 and a German and a Russian member in 1885. The revenue assigned to the debt charges was paid direct to the Caisse without passing through the ministry of finance. The assent of the Caisse (as well as that of the sultan) was necessary before any new loan could be issued, and in the course of a few years from its creation this body acquired very extensive powers. Besides the Caisse there was the Railway Board, which administered the railways, telegraphs and port of Alexandria for the benefit of the bondholders, and the Daira and Domains commissions, which administered the estates mortgaged to the holders of those loans. Each of the three boards last named consisted of an Englishman, a Frenchman and an Egyptian.

The war against bankruptcy.

The financial policy of the Egyptian government was directed to placing the country in a position to resume full payment of the interest on the debt in 1887, and thereby to avoid the appointment of an international commission. By the exercise of the most rigid economy in all branches this end was attained, though budgetary equilibrium was only secured by a variety of financial expedients, justified by the vital importance of saving Egypt from further international interference. By such means this additional complication was averted, but the struggle to put Egypt in a genuinely solvent position was by no means over. It was not until his report on the financial results of 1888 that Sir Evelyn Baring (afterwards Lord Cromer) was able to inform the British government that the situation was such that "we may take a series of untoward events seriously to endanger the stability of Egypt for the first time in its history; the solvency of the Egyptian government is further weakened by the Great Eastern debt." From this moment the corner was turned, and the era of financial prosperity commenced. The results of the labours of the preceding six years began to manifest themselves with a rapidity which surprised the most sanguine observers. The principal feature of the successive Egyptian budgets of 1890–1894 was the fiscal relief afforded to the population. From 1894 onward more attention was paid than had hitherto been possible to the legitimate demands of the spending departments and to the prosecution of public works. Of these the most notable was the construction (1898–1902) of the Assuan dam, which by bringing more land under cultivation permanently increased the resources of the country and widened the area of taxation.

With the accumulating proofs of the financial stability of the country various changes were made in connexion with the debt charges. With the consent of the powers a General Reserve Fund was created by decree of the 21st of July 1888, into which was paid the Caisse's half-share in the eventual surplus of revenue. This fund, primarily intended as a security for the bondholders, might be drawn upon for extraordinary expenditure with the consent of the commissioners of the Caisse. Large sums were so advanced for the purposes of drainage and irrigation and other public works, and in relief of taxation. The defect of this arrangement consisted in the necessity of obtaining the consent of the commissioners—a consent sometimes withheld on purely political grounds. At the same time it is believed that but for the faculty given by the decree of 1888 to spend the General Reserve Fund on public works, the financial system elaborated by the London Convention would have broken down altogether. Between 1888 and 1904 about £10,000,000 was devoted from this fund to public works.

In June 1890 the assent of the powers was obtained to the conversion of the Preference (Privileged), Domains and Daira loans on the following conditions, imposed at the initiative of the French government:

1. The employment of the economies resulting from the conversion was to be the subject of future agreement with the powers.

2. The Daira loan was to be reimbursed at 8½% instead of 8% as provided by the Law of Liquidation.

3. The sales of Domains and Daira lands were to be restricted to £5,000,000 a year each, thus prolonging the period of liquidation of those estates.

The interest on the Preference stock was reduced from 5% to 3½%, and on the Domains from 5 to 4½%. As regards the Daira loan, there was no apparent reduction in the rate of interest, which remained at 4%, but the bondholders received £85 of the new stock for every £100 of the old. The capital of the debt was increased by £1,045,000 by these conversions, while the annual economy to the Egyptian government amounted at the time of the conversion to £3,348,000. Further, an engagement was entered into that there should be no reimbursement of the loans till 1905 for the Preference and Daira, and 1908 for the Domains. By an arrangement concluded in June 1898, between the Egyptian government and a syndicate, the unsold balance of the Daira estates was taken over by the syndicate in October 1905, for the amount of the debt remaining, when the Daira loan ceased to exist. The fund formed by the accumulation of the economies resulting from the conversion of the Preference Preference Preferred stock was known as the Conversion Economies Fund. The fund could not be used for any purpose without the consent of the powers, and the money paid into it was invested by the Caisse in Egyptian stock. The fund therefore acted as a very expensive sinking fund, the market price of the stock purchased being above par. Up to 1904 the consent of the powers to the employment of this fund for any purpose of public utility was withheld. On the 21st of December of that year the fund amounted to £6,031,000. It may be added that besides the General Reserve Fund and the Conversion Economies Fund, there existed another fund called the Special Reserve Fund. This was constituted in 1886 and was chiefly made up of the net savings of the Egyptian government on its share of the annual surpluses from revenue. Of the three funds this last-named was the only one at the absolute disposal of the government. The whole of the extraordinary expenditure of the Sudan campaign of 1896–1898, with the exception of £800,000 granted by the British government, was paid out of this fund—a sum amounting in round figures to £1,500,000.

Notwithstanding all the hampering conditions stated, the prosperity of the country became more manifest each succeeding year. During the four years 1883–1886, both inclusive, the aggregate deficit amounted to £2,606,000. In 1887 there was practical equilibrium in the budget, in 1888 there was a deficit of £53,000. In 1889 there was a surplus of £2,181,000, and from that date onward every year has shown a surplus. In 1895 the surplus exceeded, for the first time, £1,000,000. The growth of revenue was no less marked. In 1883—the first complete year after the British occupation—the revenue was slightly under 9 millions. This sum was collected with difficulty. The revenue steadily rose until, in 1890, the figure of 10 millions was exceeded. In 1897 a figure of over 12 millions was attained. Continuing to rise with ever-increasing rapidity, a revenue of close on 12 millions was collected in 1901 and 1902, in spite of the fact that during the latter of these two years the Nile flood was one of the lowest on record. In 1903 the revenue amounted to 12½ millions, and in 1904 the unprecedented figure of £13,906,000 was reached. Yet during this period the amount of direct taxation remitted reached £1,000,000 a year. Arrears of land tax to the extent of £1,245,000 were cancelled. In indirect taxation the salt tax had been reduced by 40%, the postal, railway and telegraph rates lowered, octroi duties and bridge and lock dues abolished. The only increase of taxation had been on tobacco, on which the duty was raised from £
P.T. 14 to P.T. 20 per kilogramme. At the same time the house duty, with the consent of the powers, had been imposed on European residents. The fact that during the period under review Egypt suffered very severely from the general fall in the price of commodities makes the prosperity of the country the more remarkable. Had it not been for the great increase of production as the result of improved irrigation and the fiscal relief afforded to landowners, the agricultural depression would have impaired the financial situation. In this connection it should be stated that during 1890 the reassessment of the land tax, a much-needed reform, was seriously taken in hand. The existing assessment, made before the British occupation, had long been condemned by all competent authorities, but the inherent intricacies and difficulties of the problem had hitherto postponed a solution. After careful study and a preliminary examination of the land, a scheme was passed which has given satisfaction to the landowning community, and which distributes the tax equitably in proportion to the fertility of the soil. The reassessment was completed in 1897.

While the country thus prospered it also suffered greatly from the restrictions imposed by the system of international control. The cost of international financial liberty.

This system produced a great disproportion between the sums available for capital and those available for administrative expenditure. Although the money for public works could be obtained out of grants from the General Reserve Fund, the government was compelled to provide a sufficient sum to keep those works in order. Moreover, to avoid having to pay half the amount received into the General Reserve Fund, the government was compelled to keep certain items of revenue and expenditure out of the accounts altogether—a violation of the principles of sound finance. Then there was the glaring anomaly of allowing the Conversion Economies to accumulate at compound interest in the hands of the commissioners of the Caisse, instead of using the money for remunerative purposes. The net result of internationalism was to impose an extra charge of about £1,750,000 a year on the Egyptian treasury.

All these cumbersome restrictions were swept away by the khedivial decree of the 28th of November 1904, a decree which received the assent of the powers and was the result of the Anglo-French agreement of April 1904 (see § History). The decree did not affect the inability of Egypt to tax foreigners without their consent nor remove the right of Turkey to veto the issue of new loans, but in other respects the financialchanges made by it were of a radical character. The main effect was to give to the Egyptian government a free hand in the disposal of its own resources so long as the punctual payment of interest on the debt was assured. The plan devised by the London Convention of fixing a limit to administrative expenditure was abolished. The consent of the powers to the issue of new loans was no longer required. The Caisse itself remained, but shorn of all political and administrative powers, its functions being strictly limited to receiving the assigned revenues and to ensuring the due payment of the coupon. The nature of the assigned revenue was altered, the land tax being substituted for those previously assessed, that tax being chosen as it had a greater character of stability than any other source of revenue. By this means Egypt gained complete control of its railways, telegraphs, the port of Alexandria, and the customs, and as a consequence the mixed administration known as the Railway Board ceased to exist. Moreover, it was provided that when the Caisse had received from the land tax the amount needed for the service of the debt, the balance of the tax was to be paid direct to the Egyptian treasury. The Conversion Economies Fund was also placed at the free disposal of the Egyptian government. The General Reserve Fund ceased to exist, but in the better security of the bondholders a reserve fund of £1,800,000 was constituted and left in the hands of the Caisse to be used in the highly improbable event of the land tax being insufficient to meet the debt charges. Moreover, the Caisse started under the new arrangement with a cash balance of £1,250,000. The interest of the money lying in the hands of the Caisse goes towards meeting the debt charges and thus reduces the amount needed from the land tax. The bondholders gained a further material advantage by the consent of the Egyptian government to delay the conversion of the loans, which under previous arrangements they were free to do in 1905. It was agreed that there should be no conversion of the Guaranteed or Privileged debts before 1910 and no conversion of the Unified debt until 1912. Such were the chief provisions of the khedivial decree, and in 1905, for the first time, it was possible to draw up the Egyptian budget in accordance with the needs of the country and on perfectly sound foundations.

In the system adopted in 1905 and since maintained, recurring and non-recurring expenditure were shown separately, the non-recurring expenditure being termed "special." At the same time a new General Reserve Fund was created, made up chiefly of the surpluses of the old General Reserve, Special Reserve and Consolidation Economies funds. This new fund started with a capital of £13,376,000 and was replenished by the surpluses of subsequent years, by the interest earned by its temporary investment, and by the surpluses accruing by the liquidation of the Daira and Domains loans. During 1905 and 1906 about £3,000,000 was paid into the fund and £5,000,000 was set aside for the fund from the Railway loan. This fund, which had a balance of over £12,000,000 in 1906, is taken capital expenditure on remunerative public works in Egypt and the Sudan, and while the fund lasts the necessity for any new loan is avoided. The...
The Egyptian Army.

The fellah soldier has been aptly likened to a bicycle, which although incapable of standing up alone, is very useful while under the control of a skilful master. It is generally believed that the successes gained in the time of the Pharaohs were due to foreign legions; and from Cambyses to Alexander, from the Ptolemies to Antony (Cleopatra), from Augustus to the 7th century, throughout the Arab period, and from Saladin's dynasty down to the middle of the 13th century, the military power of Egypt was dependent on mercenaries. The Mamelukes (slaves), imported from the eastern borders of the Black Sea and then trained as soldiers, usurped the government of Egypt, and held it till 1517, when the Ottomans began to rule. This form of government, speaking generally, endured till the French invasion at the end of the 18th century. British and Turkish troops drove the French out after an occupation of two years, the British troops remaining till 1803. Then Mehemet Ali, a small tobacco-man of Kavala, Macedonia, coming with Albanian mercenaries, made himself governor, and later (1811), by massacring the Mamelukes, became the actual master of the country, and after seven years' war brought Arabia under Egypt's rule. He subdued Mecca and Sennaar in 1820–22; and, having levied on Egypt a larger army, he obtained instructors from France. To them were handed over 1000 Turks and Circassians to be trained as officers, who later took command of 30,000 Sudanese. These died so rapidly in Egypt from pneumonía 1 that Mehemet Ali conscripted over 250,000 fellahin, and in so arbitrary a fashion that many peasants mutilated themselves to avoid the much-dreaded service. The common practice was to place a small piece of nitrate of silver into the eye, which was then kept tightly bandaged till the sight was destroyed. Battalions were then formed of one-eyed men, and of soldiers who, having cut off their right-hand fingers, were made to shoot from the left shoulder. Every man who could not purchase exemption, with the exception of those living in Cairo, Alexandria and Suez, on becoming 19 years old was liable nominally to 12 years' service; but many men were kept for 30 or 40 years, in spite of constant appeals. Nevertheless the experiment succeeded. The discipline, yet robust and hearty, caused their foreign leaders, gained an unbroken series of successes in the first Syrian War; and after the bloody battle of Konia (1832), where the raw Turkish army was routed and the grand vizier taken prisoner, it was only European intervention which prevented the Egyptian general, Ibrahim Pasha, from marching unopposed to the Boophorus. The defeat of the Turkish army at Nizib (Nesseb or Nisib), in the second Syrian War (1839), showed that it was possible to obtain favourable military results with Egyptians when assisted by foreigners and well commanded. Ibrahim, the hero of Konia, declared, however, that no native Egyptian ought to rise higher than the rank of sergeant; and in the Syrian campaigns nearly all the officers were Turks or Circassians, as were several non-commissioned officers. In the cavalry and artillery many of the privates were foreigners, numbers of the janissaries who escaped the massacre at Stamboul (1821) having joined Mehemet Ali's army. In the reign of Abbas, who succeeded Mehemet Ali, the Egyptian troops were driven from Nejd, and the Wahhabi state recovered its independence. The next viceroy, Said, began as an ardent soldier, but took to agriculture, and at his death (1863) 3000 men only were retained under arms. Ismail, on succeeding, immediately added 27,000 men, and in seven years was able to put 100,000 men, well equipped, in the field. He sent 10,000 men to help to suppress a rebellion in Crete, and conquered the greater part of the (Nile) Sudan; but an expedition of 11,000 men, sent to Abyssinia under Prince Hasan and Rateb Pasha, well equipped with guns and all essentials, was at last successfully handled by the British general and the Sudan was destroyed. The education of Egyptians in colonial cities had not produced the class of leaders who led the fellahin to victory at Konia.

Ismail's exactions from the Egyptian peasantries reacted on the army, causing discontent; and when he was tottering on the throne he instigated military demonstrations against his own government, and, by thus sapping the foundations of his scheme, assisted Arabi's revolution; the result was the battle of Tell el-Kebir, the British occupation, and the disbandment of the army, which at that time in Egypt proper consisted of 18,000 men. Ismail had collected 500 field-guns, 200 Armstrong cannon, and had created factories of warlike and other stores. These latter were conducted extravagantly, and badly administered.

In January 1883, Major-General Sir Evelyn Wood, V.C., was given £200,000, and directed to spend it in raising a fellahin force of 6000 men for the defence of Egypt. He was assisted at first by 26 officers, amongst whom were two who later became successively sirdars—Colonel F. Grenfell, commanding a brigade, and Lieutenant H. Kitchener, R.E., second in command of the cavalry regiment. There were four batteries, eight battalions, and a camel company. Each battalion of the 1st infantry brigade had three British mounted officers, Turks and Egyptians holding the corresponding positions in the battalions of the 2nd and 3rd Brigades. The sirdar selected these native officers from those of Arabi's followers who had been the least prominent in the recent mutiny; non-commissioned officers who had been drill-instructors in the old army were recalled temporarily, but all the privates were conscripted from their villages. The earlier merciless practice had been in theory abolished by a decree based on the German system, published in 1856; but owing to defective organization, and internal disturbances induced by Khedive Ismail's follies, the law had not been applied, and the 6000 recruits collected at Cairo in January 1883 represented the biggest and strongest peasants who could not purchase exemption by bribing the officials concerned. The difficulties experienced in applying the 1850 decree were great, but the perseverance of British officers gave the oppressed peasants, in 1883, an equitable law, which has been since improved by the decree of 1900. General considerations later led the sirdar to allow exemption by payment of (Badalia) £20 before ballot. This tax, which is popular amongst the peasantries, produced in 1900 £1,500,000, and over £250,000 in 1908. This is a marked indication of the increasing prosperity of the fellahin. A portion of the badalia is expended in the betterment of the soldier's position. He is no longer drafted into the police on completing his army service, but goes free at the end of five years with a gift of £20. The sirdar is allowed, moreover, to use £20,000 per annum of the badalia for the improvement of the education of the rank and file. As an experiment the police is now a voluntary service, except in Alexandria and Cairo, for which cities peasants are conscripted for the police under army conditions. The recruiting superintending committee, travelling through districts, supervises every ballot, and works under stringent rules which render systematic bribery difficult. The recruits who draw unlucky numbers at 19 years of age are seldom called up till they are 23, when they are summoned by name and escorted by a police-man to Cairo. To prevent substitution on the journey each recruit wears a string girdle sealed in lead. The periods of service are: with the colours, 5 years; in the reserve, 5 years, during which time they may be called up for police service, manoeuvres, &c. The pay is £3. 14s. per annum for all services, and the liberal scale of rations of meat, bread and rice remains as before in theory, but in practice the value of pay and food received is greatly enhanced. So also with the pension and promotion regulations. They were in 1882 sufficiently liberal on paper, but had never been carried into effect.

1 Similar mortality, though on a smaller scale, recurred in 1889, when Sudanese battalions coming from Suakin were detained temporarily in Cairo.
The efforts of 48 American officers, who under Gen. C. P. Stone zealously served Ismail, had entirely failed to overcome Egyptian venality and intrigue; and in spite of the military schools, with a comprehensive syllabus, the only perceptible difference between the Egyptian officer and private in 1879 consisted, according to one of the Americans, in the fact that the first was the product of the harem, and the second of the field. Marshal Marmont, writing at the close of the war, that the vast numbers of the Egyptians for endurance; and it was tested in 1883, especially in the 2nd Brigade, since its officers (Turks and Egyptians), anxious to excel as drill-masters, worked their men not only from morn till eve, but also by lamplight in the corridors of the barracks. On the 31st March 1883, ten weeks after the arrival of the first draft of recruits, about 5000 men went through the ceremonial parade movements as practised by the British guards in Hyde Park, with unusual precision. The British officers had acquired the words of command in Turkish, as used in the old army, an attempt to substitute Egyptian words having failed owing to lack of crisp, sharp-sounding words. As the Egyptian brigadier, who had spent some years in Berlin, spoke German fluently, and it was also understood by the senior British officers, that language was used for all commands given by the sirdar on that special parade. The British drill-book, minus about one-third of the least serviceable movements, was translated by an English servant crowded into a 1000-ft. British official book had been published in English and Arabic, except the new Recruiting Law (1883) and a manufacturing manual, for which French and Arabic editions are in use. The discipline of the old army had been regulated by a translation of part of the Code Napoleon, which was inadequate for an Eastern army, and the sirdar replaced it by the British Army Act of 1881, slightly modified, and printed in Arabic.

The task undertaken by the small body of British officers was difficult. There was no point in the former administration of the army acceptable to English gentlemen. That there had been no adequate auxiliary departments, without which an army cannot move or be efficient, was comparatively a minor difficulty. To succeed, it was essential that the fellah should be taught that discipline might be strict without being oppressive, that pay and rations would be fairly distributed, that brutal usage by superiors would be checked, that complaints would be thoroughly investigated, and impartial justice meted out to soldiers of all ranks. An epidemic of cholera in the summer of 1883 gave the British officers their first chance of acquiring the esteem and confidence of their men, and the opportunity was nobly utilized. While the patient fellah, resigned to the decrees of the Almighty, saw the ruling Egyptian class hurry away from Cairo, he saw also those of his comrades who were stricken tenderly nursed, soothed in death's struggles, and in many cases actually washed, laid out and interred by their new self-sacrificing and determined masters. The regeneration of the fellahin army dates from that epidemic.

When the Egyptian Army of the Delta was dispersed at Tell el-Kebir, the khedive had 40,000 troops in the Sudan, scattered from Massawa on the Red Sea to 1200 m. towards the west, and from Wadi Halfa, 1500 m. southward to Wadelai, near Albert Nyanza. These were composed of Turks, Albanians, Circassians and some Sudanese. Ten thousand fellahin, collected in March 1883, mainly from Arab's former forces, set out from Durn, 100 m. south of Khartoum, in September 1883, under Hicks Pasha, a dauntless retired Indian Army officer, to vanquish the Mahdi. They disappeared in the deserts of Kordofan, where they were destroyed by the Mahdi's about 50 m. south of El Obeid. In the wave of successful rebellion, except at Khartoum, few of the Egyptian garrisons were killed when the papers fell, long residence and local family ties rendering easy the English officers, and the papers in the hands of very necessary British officers. Baker Pasha, with about 4000 constabulary, who were old soldiers, attempted to relieve Tokar in February 1884. He was attacked by 1200 tribesmen and utterly routed, losing 4 Krupp guns, 2 machine guns and 3000 rifles. Only 1400 Egyptians escaped the slaughter.

The sirdar made an attempt to raise a battalion of Albanians, but the few men obtained mutinied when ordered to proceed to the Sudan, and it was deemed advisable, after the ringleaders had been executed, to abandon the idea, and rely on blacks to stiffen the fellahin. Then the 9th (Sudanese) Battalion was created for service at Suakin, and four others having been successively added, these (with one exception—at Gedaref) have since borne the brunt of all the fighting which has been done by the khedivial troops. The Egyptian troop operations near Suakin behaved well; and there were many instances of personal gallantry by individual soldiers. In the autumn of 1884, when a British expedition went up the Nile to endeavour to relieve the heroic Gordon, besieged in Khartum, the Egyptians did remarkably good work on the line of communication from Assuit to korti, a distance of 800 m., and the training and experience thus gained were of great value in subsequent operations. The honesty and discipline of the fellah were shown to be undoubtedly of a high order. When the crews of the whale-boats were conveying stores, the forwarding officers tried to keep brandy and such like medical comforts from the European crews, coffee and tea from Canadian voyageurs and sugar from kroo boys. The only immaclulate carrier was the Egyptian. A large sum of specie having failed under British escort to reach Dongola, an equivalent sum was handed to an Egyptian. On the 2nd of September 1888, the large depots of stores at Assuan, Halfa and Dongola could only be cursorily supervised by British officers, and yet when the stores were received at the advance depot the losses were infinitesimal.

The British officers have imparted energy and activity into Egyptians of all ranks. The scientific professional knowledge of the native officers, taught under British gentlemen, and the constant hard work cheerfully rendered by the fellahin soldiers, were the main factors of the success achieved at Omdurman on the 2nd of September 1888. The large depots of stores at Assuan, Halfa and Dongola could only be cursorily supervised by British officers, and yet when the stores were received at the advance depot the losses were infinitesimal.

The nature of the fellah is unrivalled. Born in the valley of a great river, he resembles in many respects the Bengali, who exists under similar conditions; but the Egyptian character has proved capable of greater improvement. He is the strongest in frame, and can undergo greater exertion. Singularity unemotional, he stood steady at Tell el-Kebir after Arabi Pasha and all his officers, from general to subaltern, had fled, and gave way only when decimated by the British field artillery firing case shot. At El Teb, however, in 1884, he allowed himself to be slaughtered by tribesmen formerly despaired, and only about one-fourth of the force under General Valentine Baker escaped. Baker Pasha's force was termed consubstantial, yet his men were all old soldiers, though new to the present leader and half of their battalion of strange British officers. Since that fatal day, however, many of the fellahin have shown they are capable of devoted conduct, and much has been done to raise in the soldiers a sense of self-respect, and, in spite of centuries of oppression, of veracity. The barric-square drill was smart under the old system, but there was no fire discipline, and all individuality was crushed. Now both are encouraged, and the men, receiving their full rations, are unsurpassable in endurance at work and in marching. All the troops present in the surprise fight when the Dervish force was destroyed at Firket in June 1866 had covered long distances, and one battalion (the 10oth Sudanese) accomplished 90 m. within 72 hours, including the march back to railroad immediately after the action. The troops under Colonel Parsons, Royal Artillery, who beat the Dervishes at Gedaref, were so short of British officers that all orders were necessarily given in Arabic and carried to commanders of units by Arabs. While the Egyptian battalion was attacking in line, it was halted to repel a rush from the rear, and front and rear ranks were simultaneously engaged, firing in opposite directions—yet the fellahin were absolutely steady; they shot well and showed no signs of trepidation. On the other hand, neither was there any exultation after their victory. It has been aptly said the fellah would
make an admirable soldier if he only wished to kill some one!" The fellahin furnish three squadrons, five batteries, three garrison artillery companies and nine battalions.

The well-educated Egyptian officer, with his natural aptitude for figures, does subordinate regimental routine carefully, and works well when supervised by men of stronger character. The ordinary Egyptian is not self-reliant or energetic by nature, and, like most Eastern people, finds it difficult to be impartial where social and other personal relations are in the balance. The black soldier has, on the other hand, many of the finest fighting qualities. This was observed by British officers, from the time of the preliminary operations about Kosha and at the attack near Ginnis in December 1885 down to the brilliant operations in the pursuit of the Mahdists on the Blue Nile after the battle of Gedaref (subsequent to the battle of Omdurman), and the fighting in Kordofan in 1890, which resulted in the death of the khilafa and his amirs.

Black soldiers served in the army of Mehemet Ali, but their fighting value was not then duly appreciated. Prior to the death of the khilafa, many of his soldiers deserted to join their brethren who had been captured by the sirdar's troops, during the gradual advance up the Nile. After 1890 many more enlisted: the greatest number were Shilluks and Dinkas coming from the country between Fashoda and the equatorial provinces, but a proportion of the westerners and some from Wadai and Bornu. Many were absolute savages, difficult to control, wayward and thoughtless like children. Sudanese are very excitable and apt to get out of hand; unlike the fellahs they are not fond of drill, and are slow to acquire it; but their dash, pugnacious instincts and desire to close with an enemy, are valuable military qualities. The Sudanese, moreover, shoot better than the fellahin, whose eyesight is often defective. The Sudanese captain can seldom read or write, and is therefore in the hands of the Egyptian-born company quartermaster-sergeant as regards pay and clothing accounts. He is slow, and as a rule has little knowledge of drill. Nevertheless he is self-reliant, much respected by his men, and can be trusted in the field to carry out any orders received from his British officer. The most efficient companies in the Sudanese battalions are apparently those in which the captain is a black and the lieutenants are Egyptians.

In 1898 the Egyptian army, with a total establishment of 18,000, consisted of three regiments of cavalry (composed of Sudanese) each numbering 116 men; four batteries of field artillery and a Maxim battery, horses and mules being used, with a total strength of 130; two camel corps and about 120 mules of all ranks (for all the Sudan); and nine fellahin and six Sudanese infantry battalions, 10,631 of all ranks. Every battalion receives two additional companies as a reserve, and takes the field with six companies. The armament of the infantry is Martini-Henry rifle and bayonet; of the cavalry, lance, sword and carbine.

There are seven gunboats on the Nile.

The medical department (reorganized in 1883 by Surgeon-Major J. G. Rogers) at the time of the cholera epidemic (controls in place) fourteen station hospitals, and in war furnishes a mobile field hospital to each brigade. There are also veterinary station hospitals. The supply department controls mills at Tur, Halfa and Khartum.

The stringent system of selecting British officers, originated by the first sirdar in 1835, is shown by the fact that of the 24 employed commanding the army, 14 rose to be generals. The competition for employment in the army is still severe. In 1908 there were 140 British warrant and non-commissioned officers. Four of the fellahin battalions were officered by Orientals; in the other five, British officers commanded. Seven officers were employed with the artillery, six with the camel corps. Each of the Sudanese battalions had four British officers, and each squadron of cavalry one. Twelve medical and two veterinary officers are also employed departmentally, as well as officers acting as directors of supply, &c. Since the assumption of command by the third sirdar, Colonel (afterwards Lord) Kitchener, separate pay and service services have been separately administered, and a financial secretary is charged with the duty of preparing the budget, making contracts, &c. The total annual expenditure is about 500,000.

The reorganized military school system under British control, for supplying officers, dates from 1887. The course lasts for about two years, and a limited number of students can be accommodated. The ancient system of the Sudan one-fourth of the cadets in the military school of Cairo were Sudanese. Later, however, the Sudanese cadets were transferred to a branch school at Khartum.

The army raised by the first sirdar in January 1883 was highly commended for its work on the line of communication in 1884–1885, and its artillery and camelry distinguished themselves in the action at Ginnis in February 1885. Colonel Simon then succeeded General Sir Evelyn Wood in March 1885, and while under his command the army continued to improve, and fought successful actions at Gemaiza, Argin, Toski and Tokar. At Toski the Dervish army, under the nearly annihilated the British army of Major Wingate, a perfected system of secret intelligence enabled the sirdar to bring an overwhelming force of 6 to 1 against the Dervish outposts at Firket and destroy it. At Toski, on 1st November 1885, a cavalry charge by the British general W. S. Davie, of the 6th Mounted Infantry, was a brilliant victory. Davie, by superior tactics, gave the British commander the possession of Dongola. On the 7th of August 1887 Colonel Hunter surprised and annihilated a weak Dervish garrison at Abu Hamed, to which place, by the 31st of the same month 1887, a railway had been laid down; the Sudan desert from Wadi Halfa, a distance of 230 m., the "record" construction of 5,000 yds. surveyed, embanked and laid in one day having been attained. On the 26th of December 1890, the Italian troops landed over Kassala to Colonel Parsons, R.A. On the 8th of April 1898 a British division, with the Egyptian army, destroyed the Dervish force under the amir Mahmud Ahmed, on the Atbara river. On the 2nd of December 1895 the Dervish army was annihilated at Kerey (near Omdurman), and being routed, his men dispersed; Khartum was occupied, and on the 19th of September the Egyptian forces rejoined at Khartum. On the 22nd of February, 1896, General de Gerlaf was taken from the amir Ahmed Fedil by Colonel Parsons, and on the 26th of December the army of Ahmed Fedil was finally defeated at Abu Hamid. The whole of the Dervish army was destroyed. The expedition from Wadi Halfa, from 20th March to 18th May, was unremittingly active, and resulted in the evacuation of Dongola and a junction with the British garrison. The campaign of 1884–1885 was the most successful of the Sudanese campaigns, and the war was carried on with a minimum of casualties and a minimum of expense. The campaign of 1884–1885 was the most successful of the Sudanese campaigns, and the war was carried on with a minimum of casualties and a minimum of expense. The campaign of 1884–1885 was the most successful of the Sudanese campaigns, and the war was carried on with a minimum of casualties and a minimum of expense.
Egypt. Antiquities.

The remains for archaeological investigation in Egypt may be roughly classified as material and literary: to the latter belong the texts on papyri and the inscriptions, to the former the sites of ancient towns with the temples, fortifications and houses; remains of roads, canals, quarries and other matters falling within the domain of ancient topography; the larger monuments, as obelisks, statues, stelae, &c.; and finally the small antiquities—utensils, clothes, weapons, amulets, &c. Where moisture can reach the antiquities their preservation is no better in Egypt than it would have been in other countries; for this reason all the papyri in the Delta have perished unless they happen to have been charred by fire. A terrible pest is a kind of termite which is locally abundant and has probably visited most parts of Egypt at one time or another, destroying all dead vegetable or animal material in the soil that was not specially protected.

In Lower Egypt the cities built of crude brick were very numerous, especially after the 7th century B.C., but owing to the value of stone very few of their monuments have escaped destruction: even the mounds of rubbish which marked their sites furnish a valuable manure for the fields and in consequence are rapidly disappearing. Granite and other hard stones, having but a limited use (for milestones and the like), have the best chance of survival. At Bubastis, Tanis, Behbeit (Isaum) and Helopolis considerable stone remains have been discovered. In the north of the Delta wherever salt marshes have prevented cultivation in modern times, the mounds, such as those of Pelusium, still stand to their full height, and the most important are covered with ruins of brick structures of Byzantine and Arab date.

Middle and Upper Egypt were less busy and prosperous in the far ages than Lower Egypt. There was consequently somewhat less consumption of the old stone-work. Moreover, in many places equally good material could be obtained without much difficulty from the cliffs on both sides of the Nile. Yet even the buried portions of limestone buildings have seldom been permitted to survive on the cultivated land; the Nubian sandstone of Upper Egypt was of comparatively little value, and, generally speaking, buildings in that material have fallen into decay rather than been destroyed by quarrying.

Starting from Cairo and going southward we have first the great pyramid-field, with the necropolis of Memphis as its centre; stretching from Abū Roash on the north to Lisht on the south, it is followed by the pyramid group of Dahshūr, the more isolated pyramids of Mēdūm and Il-lāhūn, and that of Hawārā in the Fayūm. On the east bank are the limestone quarries of Turra and Masārā opposite Memphis. South of the Fayūm on the west bank is the temple of the 18th dynasty. The site of Ḥer-ākān, Meir and Assītū, and on the east bank those of Beni Hasan, the rock-cut temple of Speos Artemidos, the tombs of El Bershā and Sheikh Said, the tombs and stelae of El Amarna with the alabaster quarries of Hanub in the desert behind them, and the tombs of Deir el Gebrāwī. Beyond Assītū are the tombs of Dronkā and Rifā, the temples of Abydos and Dendera, and the tombs, &c., at Akhmīm and Kasr es Saiyād. Farther south are the stupendous
ruins of Thebes on both sides of the river, the temple of Esna, the ruins and tombs of El Kab, the temple of Edfu, the quarries of Siliqa and the temple of Owen, followed by the inscribed rocks of the First Cataract, the tombs and quarries of Assuan and the temples of Philae.

In Nubia, owing to the poverty of the country and its scanty population, the proportion of monuments surviving is infinitely greater than in Egypt. Here are the tombs of Debbá, the temple and quarries of Kertassi, the temples of Kalaba, Râet el Wali, Dendur, Gerf Husén, Dákka, Maharaka, Es-Sebûâ, 'Amâda and Derr, the grottos of Illes ya, the tombs of Aniba, the temple of Ibrim, the great rock-temples of Abû-Simbel, the temple at Jebel Abâd and Wadi Halfa, the forts and temples of Semna, the temples of Amûra (Merotic) and Suleb. Beyond are the Ethiopian temples and pyramids of Jebel Barkal and the other pyramids of Napata at Tangassî, &c., the still later pyramids of Meroe at Begerawa, and the temples of Meseawarat and Naga reaching to within 50 m. of Khartum.

Outside the Nile valley on the west are temples in the Great and Little Oases and the Oasis of Ammon: on the east quarries and stelae on the Hammamât road to the Red Sea, and mines and other remains at Wadi Mahârâ and Serîbêt el Khâdim in the Sinai peninsula. In Syria there are tables of conquest on the rocks at the mouth of the Nahr el Kebîl.

Of the collections of Egyptian antiquities in public museums, those of the British Museum, Leiden, Berlin, the Louvre, Turin were already very important in the first half of the 19th century, also in a less degree those of Florence, Bologna and the Vatican. Most of these have since been greatly increased and many others have been created. By far the largest collection in the world is that at Cairo. In America the museums and universities of Boston, Chicago, Philadelphia, San Francisco and New York have collections of greater or less interest. Besides these the museums of Edinburgh, Liverpool, Manchester and Oxford are noteworthy in Great Britain for their Egyptian antiquities, as are those of St Petersburg, Vienna, Marseilles, Munich, Copenhagen, Palermo and Athens; there are also collections in most of the British colonies. Private collections are numerous.

**Literary Records.**—In estimating the sources of information regarding pre-Christian Egypt, the native sources, first opened to us by Champollion, are infinitely the most important. With very few exceptions they are contemporary with the events which they record. Of the composition of history and the description of their own manners and customs by the Egyptians for posterity, few traces have reached our day. Consequently the information derived from their monuments, in spite of their great abundance, is of a fortuitous character. For one early papyrus that survives, many millions must have perished. If the journals of accounts, the letters and business documents, had come down to us en masse, they would no doubt have yielded to research the history and life of Egypt day by day; but those that now represent a thousand years of the Old Kingdom and Middle Kingdom together would not half fill an ordinary manuscript chest. A larger proportion of the records on stone have survived, but that an event should be inscribed on stone depends on a variety of circumstances and not necessarily on its importance. There may seem to be a great abundance of Egyptian monuments, but this is due to cover an enormous space of time, and even in the periods which are best represented, gravestones recording the names of private persons with a prayer or two are scarcely material for history. A scrap of annals has been found extending from the earliest times to the Vth Dynasty, as well as a very fragmentary list of kings reaching nearly to the end of the Middle Kingdom, to help out the scattered data of the other monuments. As to manners and customs, although we possess no systematic descriptions of them from any native source, the native artists and scribes have presented us with exceptionally rich materials in the painted and sculptured scenes of the tombs from the Old and Middle Kingdoms and the New Empire. For the Deltaic dynasties these sources fail absolutely, the scenes being then either purely religious or conventional imitations of the earlier ones.

Fortunately the native records are largely supplemented by others: valuable information comes from cuneiform literature, belonging to two widely separated periods. The first group is contemporary with the XVIIIth and XIXth Dynasties and consists in the first place of the Tell el Amarna tablets with others related to them, containing the reports of governors of the Syrian possessions of Egypt, and the correspondence of the kings of Babylonia, Assyria, Mitanni and Khatti (the Hittites) with the Pharaohs. The sequel to this is furnished by Winckler’s discovery of documents relating to Rameses II. of the XIXth Dynasty in the Hittite capital at Boghaz Keui (see also Hittites and Pteria). The other group comprises the annals and inscriptions of the Assyrian kings Esarhaddon and Assur-bani-pal, recording their invasions of Egypt under the XXVth Dynasty. There are also a few references to Egypt of later date down to the reign of Darius. In Hebrew literature the Pentateuch, the historical books and the prophets alike contain scanty but precious information regarding Egypt. Aramaic papyri written principally by Jews of the Persian period (5th century B.C.) have been found at Syene and Memphis.

Of all the external sources the literary accounts written in Greek are the most valuable. They comprise fragments of the native historian Manetho, the descriptions of Egypt in Herodotus and Diodorus, the geographical accounts of Strabo and Ptolemy, the treatise of Puteanus on Isis and Osiris and other monographs or scattered notices of less importance. Our knowledge of the history of Alexander’s conquest, of the Ptolemies and of the Roman occupation is almost entirely derived from Greek sources, and in fact almost the same might be said of the history of Egypt as far back as the beginning of the XXVth Dynasty. The non-literary Greek remains in papyri and inscriptions which are found in great abundance throw a flood of light on life in Egypt and the administration of the country from the time of Ptolemy Philadelphus to the Arab conquest. On the other hand, papyri and inscriptions in Latin are of the greatest rarity, and the literary remains in that language are of small importance for Egypt.

Arabic literature appears to be entirely barren of authentic information regarding the earlier condition of the country. Two centuries of unchallenged Christianity had broken almost completely the traditions of paganism, even if the Moslems had been willing to consider them, either in their factual accounts of the origins of cities, &c., or elsewhere.

**B. The Country in Ancient Times.**—The native name of Egypt was Ktmi (KM T), clearly meaning “the black land,” Egypt being so called from the blackness of its alluvial soil (cf. Plut. De Is. et Os. cap. 33): in poetical inscriptions Ktmi is often opposed to Tshtr, “the red land,” referring to the sandy deserts around, which however, would probably be included in the term Ktmi in its widest sense. Egypt is called in Hebrew Miram, čp,'o, possibly a dual form describing the country in reference to its two great natural and historical divisions of Upper Egypt and Lower Egypt: but Miram (poetically sometimes Mzôr) often means Lower Egypt, Upper Egypt being named Pathros, “the south land.” In Assyrian the name was Muṣrî, Migîr: in Arabic it is Miṣr, pronounced Maṣr in the vulgar dialect of Egypt. These names are certainly of Semitic origin and perhaps derive from the Assyrian with the meaning “frontier-land” (see Miṣrî). Winckler’s theory of a separate Muṣrî immediately south of Palestine is now generally rejected (see, for instance, Ed. Meyer, Die Israeliten und ihre Nachbarstämme, 445). The Greek Αἰγυπτος (Aegyptos) occurs as early as Homer; in the Odyssey it is the name of the land of Pharaoh (the land of the country), as well as of the whole country (see Αιγυπτός). Brugsch’s derivation from Hakeptah, a name of the northern capital, Memphis, though attractive, is unconfirmed.

Egypt normally included the whole of the Nile valley from the First Cataract to the sea; pure Egyptians, however, formed the population of Lower Nubia above the Cataract in prehistoric
times; at some periods also the land was divided into separate kingdoms, while at others Egypt stretched southward into Nubia, and it generally claimed the neighbouring Libyan deserts and oases on the west and the Arabian deserts on the east to the shore of the Red Sea, with Sinai and the Mediterranean coast as far as Rhinocorura (El Arish). The physical features in ancient times were essentially the same as at the present day. The bed of the Nile was lower: it appears to have risen by its present rate of about a foot in a century. In the north of the Delta, however, there was a sinking of the land, in consequence of which the accumulations on some of the ancient sites there extend below the present sea-level. On the other hand at the south end of the Suez canal the land may have risen bodily, since the head of the Gulf of Suez has been cut off by a bank of rock from the Bitter lakes, which were probably joined to it in former days. The banks of the Nile and the islands in it are subject to gradual but constant alteration—and in fact several ancient sites have been much eroded or destroyed—and the main volume of the stream may in course of time be diverted into what has previously been a secondary channel. According to the classical writers, the mouths or branches of the Nile in the Delta were five in number (seven including two that were artificial): now there are only two. In Upper Egypt the main stream tended as now to flow along the eastern edge of the valley, while to the west was a parallel stream leading to the Bahr el Arab. From this, the latter, a canal or branch led to the Lake of Moeris, which, until the 3rd century B.C., filled the deep depression of the Fayum, but is now represented only by the strongly brackish waters of the Birket el Kertin, left in the deepest part. The area of alluvial land has probably not changed greatly in historic times. The principal changes that have occurred are due to the grip which civilization has taken upon the land in the course of thousands of years, often weakening but now firm. In recent days no doubt the soil was cultivated in patches, but gradually a great system of canals was organized under the control of the central government, both for irrigation and for transport. The wild flora of the alluvial valley was probably always restricted and eventually was reduced almost to the "weeds of cultivation," when every acre of soil, at one period of the year under water, and at another roasted under the burning heat of a semi-tropical sun, was carefully tilled. The acacia abounded on the borders of the valley, but the groves were gradually cut down for the use of the carpenter and the charcoal-burner. The desert was full of wild life, the balance of nature being preserved by the carnivorous animals preying on the herbivorous; trees watered by soakage from the Nile protected the undergrowth and encouraged occasional rainfall. But this balance was upset by the early introduction of the goat and later of the camel, which destroyed the sapling trees, while the grazing ones fell to the ax of the woodcutter. Thus in all probability the Egyptian deserts have become far poorer in animals and trees than they were in primitive times. Much of Lower Egypt was left in a wilder state than Upper Egypt. The marshy lands in the north were the resort of fishermen and fowlers, and the papyrus, the cultivation of which was a regular industry, protected an abundance of wild life. The abandonment of papyrus culture in the 8th century B.C., the neglect of the canals, and the intrusion of the sea, have converted much of that country into barren salt marsh, which only years of draining and washing can restore to fertility.

The rich alluvial deposits of the Nile which respond so readily to the efforts of the cultivator ensured the wealth of the country. Moulded into brick, without burning, this black clay also supplied the common wants of the builder, and even the palaces of the greatest kings were constructed of crude brick. For more lasting and ornamented work the Egyptians turned to the materials which could be obtained from the rocks and deserts of the Nile valley. The chief of these was limestone of varying degrees of fineness, composing the cliffs which lined the valley from the apex of the Delta to the neighbourhood of El Kâh; the best quality was obtained on the east side opposite Memphis from the quarries of Turra and Masîra. From El Kâh southward its place was taken by Libyan sandstone, soft and easily worked, but unsuitable for fine sculpture. In the limestone was found the flint or chert used for weapons and instruments in early times. For alabaster the principal quarry was that of Hanub in the desert 10 m. behind El Amarna, but it was obtained elsewhere in the lime-stone region, including a spot near Alexandria. A hard and fine-grained quartzite sandstone was quarried at Jebel Amude behind Heliopolis, and basalt was found thence along the eastern edge of the Delta to near the Wadi Tumilât. Red granite was obtained from the First Cataract, breccia and diorite were quarried from very early times in the Wadi Hammâmât, on the road from Coptos to the Red Sea, and porphyry was brought, chiefly in Roman times but also in the prehistoric age, from the same region at Jebel Dokhân. Egypt was poor in metals. Gold was obtained chiefly from Nubia: iron was found in small quantities in the country and at one time was worked in the neighbourhood of Assûn. Some copper was obtained in Sinai. Of stones that were accounted precious Sinai produced turquoise and the Egyptian deserts garnet, carnelian and jasper.

The native supply of wood for industrial purposes was exceedingly bad: there was no native wood long enough and straight enough to be used in joiners’ work or sculpture without fitting and patching: palm trees were abundant, and if the trees could be spared, the fruit and stalks could be used for roofing. For boatbuilding papyrus stems and acacia wood were employed, and for the best work cedar-wood was imported from Lebanon.

Egypt was isolated by the deserts and the sea. The Nile valley afforded a passage by ship or on foot into Nubia, where, however, little wealth was to be sought, though gold and rarities from the Sudan, such as ivory and ebony, came that way and an armed raid could yield a good spoil in slaves and cattle. The mines of the Arabians, their split stems could be used for roofing. For boatbuilding papyrus stems and acacia wood were employed, and for the best work cedar-wood was imported from Lebanon. of Egypt shows remarkable coincidences with that of Babylonia, the language is of a Semitic type, the religion may well be a compound of a lower African and a higher Asiatic order of ideas. According to the evidence of the monuments, the Egyptians were of the slender build, with dark hair and of Caucasian type. Dr. Elliott Smith, who has examined thousands of skeletons and mummies of all periods, finds that the prehistoric population of Upper Egypt, a branch of the North African-Mediterranean-Arabian race, changed with the advent of the dynasties to a stronger type, better developed than before in skull and muscle. This was apparently due to admixture with the Lower Egyptians, who themselves had been affected by Syrian immigration. Thereafter little further change is observable, although the rich lands of Egypt must have attracted foreigners from all parts. The Egyptian artists of the New Empire assigned distinctive types of feature as well as of dress to the different races with which they came into contact, Hittites, Syrians, Libyans, Bedouins, negroes, &c.

The people of Egypt were not naturally fierce or cruel. Intellectually, too, they were somewhat sluggish, careless and unbusinesslike. In the mass they were a body of patient labourers, tilling a rich soil, and hating all foreign lands and ways. The wealth of their country gave scope for ability within the population and also attracted it from outside: it enabled the kings to organize great monumental enterprises as well as to arm irresistible rafts upon the inferior tribes around. Urged on by necessity and opportunity, the Egyptians possessed sufficient enterprise and originating power to keep ahead of their neighbours in most departments of civilization, until the more warlike empires of Assyria and Persia overthrew them, and the keener intellects of the Greeks outshone them in almost every department. The debt of civilization to Egypt as a pioneer must be considerable, above all perhaps in religious thought. The moral ideals of its nameless teachers were high from an early date: their conception of an after-life was exceedingly vivid: the piety of the Egyptians in the later days was a matter of wonder and scoffing to their contemporaries; it is generally agreed that certain features in the development of Christianity are to be traced to Egypt as their birthplace and nidus.

Divisions.—In ancient times Egypt was divided into two regions, representing the kingdoms that existed before Memes. Lower Egypt, comprising the Delta and its borders, formed the "North Land," To-meh, and reached up the valley to include Memphis and its province or "nome," while the remainder of the Egyptian Nile valley was "the South," Shems (SWM). The south, if only as the abode of the sun, always had the precedence over the north in Egypt, and the west over the east. Later the two regions were known respectively as P-to-em, "the south land," and P-to-neh, "the north land." In practical administration this historic distinction was sometimes observed, at others ignored, but in religious tradition it had a firm hold. In Roman times a different system marked off a third region, namely Middle Egypt, from the point of the Delta southward. Theoretically, as its name Heptanomis implies, this division contained seven nomes, actually from the Hermopolite on the south of Memphite on the north (excluding the Aswanite according to the papyri). Some tendency to this existed earlier. Egypt to the south of the Heptanomis was the Thebes, called P-tom-en-ne, "the province of Thebes," as early as the XXVIth Dynasty. The Thebaïs was much under the influence of the Ethiopian kingdom, and was separated politically in the troubled times of the XXVIIIth Dynasty, though Upper and Lower Egypt was restored in the XXVIth Dynasty.

If Upper and Lower Egypt represented ancient kingdoms, the nomes have been thought to carry on the traditions of tribal settlements. They are found in inscriptions as early as the end of the IIIrd Dynasty, and the very name of Thoth, and that of another very ancient god, are derived from those of two contiguous nomes in Lower Egypt. The names are written by special emblems placed on standards, such as an ibis, a jackal, a hare, a feathered crown, a sistrum, a blade, &c., suggesting tribal badges. Some names having a common badge but distinguished as "nearer" or "further," i.e. "northern" or "southern," have simply been split, as they are contiguous: in one case, however, corresponding "eastern" and "western" Harpoon nomes are widely separated on opposite sides of the Delta. In a few cases, such as "the West," "the Beginning of the East," it is obvious that the names are derived solely from their geographical situation. It is quite possible that the divisions are geographical in the main, but it seems likely that there were also religious, tribal and other historical reasons for them. How their boundaries were determined is not certain: in Upper Egypt in many cases a single nome embraced both sides of the river. The number and nomenclature of the nomes were never absolutely fixed. In temples of Ptolemaic and Roman age the full series is figured presenting their tribute to the god, and this series approximately agrees with the scattered data of early monuments. The normal number of the nomes in the sacred lists appears to be 42, of which 22 belonged to Upper Egypt and 20 to Lower Egypt. In reality again these nome-divisions were treated with considerable freedom, being split or reunited and their boundaries readjusted. Each nome had its metropolis, normally the seat of a governor or monarch and the centre of its religious observances. During the New Empire, except at the beginning, the nomes seem to have been almost entirely ignored: under the Deltaic dynasties (except of course in the traditions of the sacred writing) they were named after the metropolis, as "the province (osk) of Busiris," "the province of Sai," &c.: hence the Greek names Boueispeia, &c. The Arzinoite nome was added by the Ptolemies after the draining of the Lake of Moeris (g.s.), and in the later Ptolemaic and the Roman times many changes and additions to the list must have been made. In the various texts the "provinces" appear to have been very numerous.

See H. Brugsch, Geographische Inschriften alägyptischer Denkmäler (3 vols., Leipzig, 1857-1860), and for the names on monuments of the Old Kingdom, N. de G. Davies, Masaba of Plakhtetep and Abydos (London, 1901), p. 24 et sqq.

King and Government.—The government of Egypt was monarchical. The king (or titles see PHARAOH) was the head of the hierarchy: he was himself divine and is often styled "the good god," and was the proper mediator between gods and men. He was also the dispenser of office, confirmer of hereditary titles and estates and the fountain of justice. Oaths were generally sworn by the "life" of the king. The king wore special head-dresses and costumes, including the crowns of Upper and Lower Egypt (often united ), and the cobra upon his forehead. Females were admitted to the succession, but very few instances occur before the Cleopatras. The most notable Pharaonic queen in her own right was Hatshepsut in the XVIIIth Dynasty, but her reign was ignored by the later rulers even of her own family. A certain Nitiotiris of about the VIIIth Dynasty and Sennomphon of the XIIth Dynasty are in the lists, but are quite obscure. Yet inheritance through the female line was fully recognized, and marriage with the heiress princess was sought by usurpers to legitimate the claims of their offspring.
Often, especially in the XIIth Dynasty, the king associated his heir on the throne with him to ensure the succession.

From time to time feudal conditions prevailed: the great landowners and local princes had establishments of their own on the model of the royal court, and were with difficulty kept in order by the monarch. In rare cases during the Middle Kingdom (inscriptions in the tomb of Amen at Beni Hasan, graffiti in the quarries of Hanub) documents were dated in the years of reign of these feudal nobles. Under the Empire all power was again centered in the hands of the Pharaoh. The apportionment of duties amongst the swarm of officials varied from age to age, as did their titles. Members of the royal family generally held high office. Under the Empire Egypt was administered by a vast bureaucracy, at the head of which, responsible to the king, was the vizier, or sometimes two viziers, one for Upper Egypt, the other for Lower Egypt (in which case the former, stationed at Thebes, had the precedence). The duties of the vizier and the procedure in his court are detailed in a long inscription which is repeated in three tombs of the XVIIIth Dynasty at Thebes (Breasted, Records, II, § 663 et seq.). The strictest impartiality was enjoined upon him, and he was advised to hold aloof from the people in order to preserve his authority. The office of vizier was by no means a sinecure. All the business of the country was overlooked by him—treasury, taxation, army, law-courts, expeditions of every kind. Egypt was the vast estate of the vizier, since the vizier was the Pharaoh, the army—The youth of Egypt was liable to be called upon for service in the field under the local chiefs. Their training consisted of gymnastic and warlike exercises which developed strength and discipline that would be as useful in executing public works and in dragging large monuments as in strictly military service. They were armed in separate companies with bows and arrows, spears, daggers and shields, and the officers carried battle-axes and lances. The army, commanded in chief by the Mamluks under the V'th Dynasty, was the army of the Pharaoh in Sinai or Palestine, comprised levies from every part of Egypt and from Nubia, each under its own leader. Under the New Empire, when Egypt was almost a military state, the army was a more specialized institution, the art of war in siege and strategy had developed, divisions were formed with specific standards, there were regiments armed with battle-axes and scimitars, and chariots formed an essential part of the host. Egyptian cavalry are not represented upon the monuments, and we hear of them from such a late date as the reign of Herodotus divides the army into two classes, the Calasaries and the Hermotybes; these names, although he was not aware of it, mean respectively horse- and foot-soldiers, but it is possible that the former name was only traditional and had characterized those who fought from chariots, a mode of warfare that was obsolete in Herodotus's own day: as a matter of fact both classes are said to have served on the warships of Xerxes' fleet.

Arms and Armour.—From the contents of graves and other remains, and the sculptured and painted scenes, an approximate idea can be obtained of the weapons of the Egyptians at all periods from the prehistoric age onwards. Only a few points are here noted. Stone mace-heads are found in the earliest cemeteries, together with flint implements that may be the heads of lances, &c., and thin leaf-shaped daggers of bronze. Stone arrow-heads are common on the surface of the desert. Thin bronze arrow-heads appear at an early date; under the Empire they were stouter and furnished with a tang, and later still, towards the Greek period, they are socketed (often three-sided), or, if of iron, still stung. The wooden club, a somewhat primitive weapon, seems to have been considered characteristic of foreigners from very early times, and, in scenes dating from the Middle Kingdom, belong principally to the levies from the surrounding barbarians. The dagger grew longer and stouter, but of Pharaoh and the vizier was the stouter of the two, probably first in the hands of the Sherdana (Sardinians?), mercenaries of the time of Ramses II. A peculiar scimitar, khopsh, characteristic of the Empire. Slings are first heard of in Egyptian warfare in the 8th century B.C. The chariot was doubtless introduced with the horse in the Hyksos period; several examples have been discovered in the tombs of the New Kingdom. Shields were covered with ox-hide and furnished with round sighting-holes above the middle. Cuirasses of bronze scales were worn by the kings and other leaders. The linen corslets of the Egyptian soldiery at a later time were famous, and were adopted by the Persian army. According to the paintings of the Middle Kingdom in the tombs of Beni Hasan, the battlements of brick fortresses were studded and wrenched as an added defence. Long and massive spears. No siege engines are depicted, even in the time of the Empire, and the absence of original representations after the XXth Dynasty renders it difficult to judge the advances made in the art of war during the first half of the last millennium B.C. The inscription of Pankhi, however, proves that in the 8th century approaches and towers were raised against the walls of besieged cities.

Priesthood.—The priesthood was in a great degree hereditary, though perhaps not essentially so. In each temple the priests were divided into four orders (until Ptolemy Euergetes added a fifth), each of which served in turn for a lunar month under the chief priest or prophet. They received shares of the annual revenues of the temple in kind, consisting of linen, oil, flesh, bread, vegetables, wine, beer, &c. The "divine servants" or "prophets" had residences assigned them in the temple area. The king assumes the priestly office, and a special attention to cleanliness and ceremonial purity already implied in their ancient name. Fish and beans were then abhorred by them. Among the priests were the most learned men of Egypt, but probably many were illiterate. For the Hellenistic period see W. Otto, Priester und Tempel im hellenistischen Ägypten (Leipzig, 1905 foll.).

For ancient Egyptian life and civilization in its several departments, the principal work is Ad. Erman's Ägypten und Ägyptische Leitungen aus Alterthum und Gegenwart, translated by H. M. Tirard (London, 1894), the original Ägypten und ägyptisches Leben im Alterthum, 2 vols., was published in 1865 at Tübingen; G. Maspero, Life in Ancient Egypt and Assyria, translated by A. F. Morton (London, 1892), Lectures historiques, Paris, 1890; also J. G. Wilkinson, Manners and Customs of the Ancient Egyptians, new ed. by S. Birch (3 vols., London, 1879). The annual Archaeological Reports of the Egypt Exploration Fund contain summaries of the work done each year in the several departments of research.

Of the innumerable publications of Egyptian monuments, scenes and inscriptions, C. R. Lepsius, Denkmäler aus Ägypten und Äthiopien (Berlin, 1849-1859), and Memoirs of the Archaeological Survey of the Egypt Exploration Fund, may be specified. For collections in museums there is the monument catalogue of antiquités égyptiennes du musée de Caire; for excavations the Memoirs of the Egypt Exploration Fund, of the Research Account, of the British School of Archaeology, of the Liverpool School of Archaeology, of the Deutsche Orient-Gesellschaft, of the Henry E. School of Egypt Exploration, of the Theodore M. Davis excavations (Tomb of the Kings).

Trade and Money.—There is little evidence to show how buying and selling were carried on in ancient Egypt. A unique scene in a tomb of the IVth Dynasty, however, shows men and women exchanging commodities against each other—fish, fish-hooks, fans, necklaces, &c. Probably this was a market in the open air such as is held weekly at the present time in every considerable village. Rings of metal, gold, silver and bronze played some part in exchange, and from the Hyksos period onwards formed the usual standards by which articles of all kinds might be valued. In the XVIIIth Dynasty the value of meat, &c., was reckoned in gold; somewhat later copper seems the commonest standard, and under the Deltaic dynasties silver. But barter must have prevailed much longer. The precious metals were kept in the temples under the tutelage of the deities. During the XXVth and XXXVth Dynasties silver of the treasure of Harshafe (at Heracleopolis Magna) was commonly prescribed in contracts, and in the reign of Darius we hear of silver of the treasury of Pith (at Memphis). Aryandes, saptap of Egypt, is said by Darius to have been specially charged with the manufacture of equal fineness with that of the king in Persia: thus coinage had then begun in Egypt. But the early coins that have been found there are mainly Greek, and especially Athenian, and it was not until the introduction of a regular currency in the three
metals under the Ptolemies that much use was made of coined money.

Cotton was the staple produce of Egypt and may have been exported regularly, and especially when there was famine in other countries. In the Tell el-Amarna letters the friendly kings ask Pharaoh for “much gold.” Papyrus rolls and fine linen were good merchandise in Phoenicia in the 10th century B.C. From the earliest times Egypt was dependent on foreign countries to supply its wants in some degree. Vessels were fashioned in foreign stone as early as the 1st Dynasty. All silver must have been imported, and all copper except a little that the Pharaohs obtained from the mines of Sinai. Cedar wood was brought from the forests of Lebanon, ivory, leopard skins and gold from the south, all kinds of spices and ingredients of incense from Somaliland and Arabia, fine linen and beautifully worked vessels from Syria and the islands. Such supplies might be obtained by forcible raiding or as tribute of conquered countries, or perhaps as the free offerings of simple savages swed by the arrival of ships and civilized well-armed crews, or again by royal missions in which rich gifts on both sides were exchanged, or lastly by private trading. For deciding how large a share was due to trade, there is almost no evidence. But there are records of expeditions sent out by the king to obtain the rarities of different countries, and the hero of the Story of the Shipwrecked Sailor was upon this quest. Egyptian objects of the age of the XVIIIth Dynasty are found in the Greek islands and on the mainland among remains of the Mycenaean epoch, and on the other hand the products of the workshops of Crete and other centres of that culture are found in Egypt and are figured as “tribute of the Keftiu” in the tomb-paintings, though we have no information of any war with or conquest of that people. It must be a case of trade rather than tribute here and in like instances. According to the papyrus of Unamun at the end of the weak XXth Dynasty payment for cedar was insisted on by the king of Byblos from the Egyptian commissioner, and proofs were shown to him of payment having been made even in the more glorious times of Egypt. Trade both internal and external must have been largely in the hands of foreigners. It is impossible to say at what period Phoenician traffic by sea with Egypt began, but it existed as early as the IIIrd Dynasty. In the time of Herodotus much wine was imported from Syria and Greece. Amasis II. (c. 570 B.C.) established Naucratis as the centre of Greek trade in Egypt. Financial transactions by Jews settled at the southern extremity of Egypt, at Assuan, are found as early as the reign of Ameiniræus.

Hunting, Fishing, &c.—In the desert hunting was carried on by hunters with bows and arrows, dogs and nets to check the game. Here in ancient times were found the oryx, addax, ibex, gazelle, bubale, ostrich, hyena and porcupine, more rarely the wild ox and wild sheep (O. tauricus). All of these were considered fit for the table. The lion, leopard and jackal were not eaten. Pigeons and other birds were caught in traps, and quails were netted in the fields and on the sea-shore. In the papyrus marshes the hippopotamus was slain with harpoons, the wild boar, too, was probably hunted, and the sportsman brought down wild-fowl with the boomerang, or speared or angled for fish. Enormous quantities of wild-fowl of many sorts were taken in clap-nets, to be preserved in jars with salt. Fish were taken sometimes in hand-nets, but the professional fishermen with their draw-nets caught them in shoals. The fishing industry was of great importance; the annual catch in the Lake of Moeris and its canal formed an important part of the Egyptian revenue. The fish of the Nile, which were of many kinds (including mullets, &c., which came up from the sea), were split and dried in the sun: others were salted and so preserved. A supply of sea fish would be obtained off the coast of the Delta and at the mouth of the Lake Serbonis.

Farming, Horticulture, &c.—The wealth of Egypt lay in its agriculture. The regular inundations, the case of irrigating the rich alluvial floras in the Neolithic age, rich in a season of the year, gave immense opportunities to the industrious farmer. The normal rise of the Nile was sixteen cubits at the island of Roda, and two cubits more or less caused a failure of the harvest. In the paintings we see gardens irrigated by handbuckets and shadoofs; the latter, hung on a lever, were probably the usual means of raising water for the fields in ancient times, and still are common in Egypt and Nubia, although water-wheels have been known since the Ptolemaic age, if not earlier. Probably a certain amount of cultivation was possible all the year round, and there was perhaps a success of harvests; but there was a pause after the main harvests were gathered in by the end of April, and from then till June was the period in which taxes were collected and loans were repaid. Under the Ptolemaic régime the records show a great variety of crops, wheat and barley being probably the largest (see P. Grenfell and A. S. Hunt, Tebtunis Papyri, i. 606; J. P. Mahaffy and J. G. Smyle, Patric Papyri, iii. p. 205). Earlier the bōbē, in Greek ὄβοβα (spelt? ὄβοου?) was the main crop, and earlier again inferior varieties of wheat and barley took the lead, with bōbē apparently in the second place. The bread was mainly made of bōbē, the beer of barley. There were green crops such as clover, and lentils, peas, beans, radishes, onions, lettuces (as a vegetable and for oil), castor oil and flax were grown. The principal fruit trees were the date palm, useful also for its wood and fibre, the pomegranate, fig and fig-sycamore. The vine was much cultivated in early times, and the vintage is a subject frequently depicted. Later the wine of the Mareotic region near Alexandria was celebrated even amongst Roman epicures. Papyrus, which grew wild in the marshes, was also cultivated, at least in the later ages: its stems were used for boat-building, and according to the classical authors for rope-making, as well as for the famous writing material. About the 8th century A.D. paper drove the latter out of use, and the papyrus plant quickly became extinct. The Indian lotus described by Herodotus is found in deposits of the Roman age. Native lotuses, blue and white, were much used for decoration in garlands, &c., also the chrysanthemum and the cornflower.

See chapters on plant remains by Newberry in W. M. F. Petrie, Hesperia, Brahm and Arisinoe (London, 1896); Kahn, Gurob and Hawara (1896); V. Loret, La Flore pharaonique (2nd ed., Paris, 1902), and the authorities there cited.

Domestic Animals and Birds.—The farmer kept up a large stock of animals: in the houses there were pets and in the temples sacred creatures of many kinds. Goats browsed on the trees and herbage at the edge of the desert. Sheep of a peculiar breed with a mental twist in the head and hairy coat are figured on the earliest monuments: a more valuable variety, woolly with curled horns, made its appearance in the Middle Kingdom and pushed out the older form: sheep were driven into the ploughed fields to break the clods and trample in the seed. The oxen were long-horned, short-horned and polled. They drew the plough, trampled the corn sheaves round the circular threshing floor, and were sometimes employed to drag heavy weights. The pig is rarely figured and was less and less tolerated as the Egyptians grew in ceremonial purity. A variety of wild animals caught in the chase were kept alive and fed for slaughter. Geese and ducks of different sorts were bred in countless numbers by the farmers, also pigeons and quails, and in the early ages cranes. The domestic fowl was unknown in Egypt before the Deltic dynasties, but Diodorus in the first century B.C. describes how its eggs were hatched artificially, as they are at the present day. Bee-keeping, too, must have been a considerable industry, though dates furnished a supply of sweetening material.

The farm lands were generally held at a rent from an overlord, who might according to times and circumstances be the king, a feudal prince, or a temple-corporation. The stock also might be similarly held, or might belong to the farmers. The ordinary beast of burden, even in the desert, was the ass. The horse seems to have been introduced with the chariot during the Hyksos period. It is thought that the camel is shown in rude figures of the XXVIth Dynasty. In the Ptolemaic period it was used for desert transport and gradually became common. Strange to say,
it is only very rarely that men are depicted riding on animals, and never before the New Kingdom.

The dog was of many varieties as early as the XXIth Dynasty, when the greyhound and spaniel and other well-marked forms are seen. The cat was sometimes trained by the sportsman to catch birds. Monkeys were commonly kept as pets. The sacred beasts in the various temples, tame as far as possible, were of almost every conceivable variety, from the vulture to the swallow or the goose, from the lion to the shrew-mouse, from the hippopotamus to the sheep and the monkey, from the crocodile to the tortoise and the cobra, from the carp to the eel; the scorpion and the scarab beetle were perhaps the strangest in this strange company of deities.

For agriculture see J. J. Tylor and F. Ll. Griffith, The Tomb of Paheri at El Kab, in the Xth Memoir of the Egypt Exploration Fund. Together with hunting and fishing it is illustrated in many of the Memoirs of the Archaeological Survey of the same society. See also Lorret and M. C. Gaillard, La Faune monistique de l'ancienne Egypte (Lyons, 1905).

Law.—No code of Egyptian laws has come down to us. Diodorus names a series of Egyptian kings who were law-givers, ending with Amsamis (Amonis II) and Darius. Frequent reference is made in inscriptions to laws and customs which were traditional, and perhaps had been codified in the sacred books. From time to time regulations on special points were issued by royal decree: a fragment of such a decree, directed by Horemheb of the XVIIIth Dynasty, concerning the prosecution of the peasantry by officials and prescribing penalties, is preserved on a slab in the temple at Karnak, and enactments of Ptolomy Philadelphia and Euergetes II. are known from papyri. In the Ptolemaic age matters arising out of native contracts were decided according to native law by nomarchs, while travelling courts of ἄρματος represented the king settled litigation on Greek contracts and most other disputes. Affairs were decided in accordance with the code of the country, ἱθ ἐν άρματος, the Greek code, ἰθ θεῖον ἔθισμα, provided, it was said, on Athenian law or royal decrees. The expression of the significance of the existence remains to be ascertained. In ancient Egypt petitions were sent to the king or the great feudal landowners in whose territory the petitioner or his adversary dwelt or the injury was committed: courts were composed of royal or feudal officials, or in the New Kingdom of officials or responsible citizens. The right of appeal to the king probably existed at all times. The statement of the case and the evidence were frequently ordered to be put in writing. The evidence was supported by oath: in criminal cases, such as the harem conspiracy against Ramesses III., torture of the accused was resorted to extract evidence, the bastinado being applied on the hands and the feet. Penalties in the New Kingdom were death (by starvation or self-inflicted), fines, beating with a certain number of blows so as to open a specified number of wounds on as many different parts of the body (e.g. five wounds, i.e. on hands, feet and back?), also cutting off the nose with banishment to Nubia or the Syrian frontier. In the times of the Old Kingdom decapitation was in use, and a decree exists of the Middle Kingdom degrading a nomarch of Coptos and his family for ever from his office and from the priesthood on account of services to a rival pretender.

As to legal instruments: contracts agreed to in public or before witnesses and written on papyrus are found as early as the Middle Kingdom and perhaps belong to all historic times, but are very scarce until the XXVth Dynasty. Two wills exist on papyrus of the XXIth Dynasty, but they are isolated, and such are not again found among native documents, though they occur in Greek in the Ptolemaic age. The virtual will of a high priest of Ammon under the XXIIId Dynasty is put in the form of a decree of the god himself.

From the time of the XXVth Dynasty there is a great increase in wills against elements of a legal character, sales, loans, &c., apparently due to a change in law and custom; but after the reign of Darius I. there is again almost a complete cessation until the reign of Alexander, probably only because of the disturbed condition of the country. Under Ptolemy Philadelphia Greek documents begin to be numerous: under Euergetes II. (Physcon) demotic contracts are particularly abundant, but they cease entirely after the first century of Roman rule.

Ptolemaic contracts are not found earlier than the XXVIth Dynasty. Women had full powers of inheritance (though not of dealing with their property), and succession through the mother was of importance. In the royal line there are almost certain instances of the marriage of a brother with a heiress-sister in Pharaonic times: this was perhaps helped by the analogy of Osiris and Isis: in the Ptolemaic dynasty it was an established custom, and one of the stories of Khama, written in the Ptolemaic age, assumes its frequency at a very remote date. It would be no surprise to find examples of the practice in other ranks also at an early period, as it certainly was prevalent in the Hellenistic age, but as yet it is very difficult to prove its occurrence. The native contracts with the wife gave to her child all the husband's property, and divorce or separation was provided for, entailing forfeiture of the dowry. The "native law" of Roman times allowed a man to take his daughter away from her husband if the last quarrelled with him.

Slavery is traceable from an early date. Private ownership of slaves, captured in war and given by the king to their captor or otherwise, is certainly seen at the beginning of the XVIIIth Dynasty. Sales of slaves occur in the XXVth Dynasty, and contracts of servitude are found in the XXVIth Dynasty and in the reign of Darius, appearing as if the consent of the slave was then required. Presumably at this late period there were enunuchs in Egypt, though adequate evidence of their existence is not yet forthcoming. They must have been a more cruel people. That circumcision (though perhaps not till puberty) was regularly practised is proved by the mummies (agreeing with the testimony of Herodotus and the indications of the early tomb sculptures) until an edict of Hadrian forbade it: after that, only priests were circumcised.

Science.—The Egyptians sought little after knowledge for its own sake: they might indulge in religious speculation, but their science was no more than the knowledge of practical methods. Undoubtedly the Egyptians acquired great skill in the application of simple means to the fulfilment of the most difficult tasks. But the books that have come down to us prove how greatly their written theoretical knowledge fell short of their practical accomplishment. The explanation of the fact may partly be that the mechanical and other discoveries of the most ingenious minds among them, when not in constant requisition by later generations, were misunderstood or forgotten, and even in other cases were preserved only as rules of thumb by the craftsmen and experts, who would jealously hide them as secrets of trade. Men of genius were not wanting in the long history of Egypt; two doctors, Imhotep (Imuthes), the architect of Zoser, in the IIId Dynasty, and Amenophis (Amenhotp), son of Hap, the wise scribe under Amenophis III. in the XVIIth, actually received the honours of deification; and Hardadu under Cheops of the IVth Dynasty was little behind these two in the estimation of posterity. Such men, who, capable in every field, designed the Great Pyramids and bestowed the highest monumental fame on their masters, must surely have had an insight into scientific principles that would hardly be credited to the Egyptians from the written documents alone.

Mathematics.—The Egyptian notation for whole numbers was decimal, each power of ten up to 10,000 being represented by a different figure, on much the same principle as the Roman numerals. Fractions except ⅟ were all primary, i.e. with the numerator unity: in order to express such an idea as ⅝ the Egyptians were obliged to reduce it to a series of primary
fractions through double fractions $\frac{a}{x} + \frac{b}{y} = \frac{a+y}{x+y} + \frac{b+x}{y+x}$; this operation was performed in the head, only the result being written down, and to facilitate it tables were drawn up of the division of 2 by odd numbers. With integers, besides adding and subtracting, it was easy to double and to multiply by 10: multiplying and dividing by 5 and finding the 2/3 values were also met. The fundamental instruments of calculation, and all multiplication proceeded by repetitions of these processes with addition, e.g. $xy = (x+5)(x+2) + (x+2) = 9$. Division was accomplished by multiplying the divisor until the dividend was reached; the answer being the number of times the divisor was so multiplied. Weights and measures proceeded generally on either a decimal or a doubling system or a combination of the two. Apart from a few calculations and accounts, practically all the materials for our knowledge of Egyptian mathematics before the Hellenistic period date from the Middle Kingdom.

The principal text is the Rhind Mathematical Papyrus in the British Museum, written under a Hyksos king c. 1650 b.c.; unfortunately it is full of gross errors. Its contents fall roughly into the following scheme, but the main headings are not shown in the original:

I. Arithmetica.—A. Tables and rule to facilitate the employment of fractions

(a) Table of the divisions of 2 by odd numbers from 3 to 99 (e.g. 2 + 11 = 1 + 9), see above.

(b) Conversion of compound fractions (e.g. $\frac{1}{x} + \frac{1}{y}$), with rule for finding $\frac{1}{x}$ of a fraction.

B. The "bread" calculation—a division by 10 of the units 1 to 9.

C. "Completing" calculation, i.e. (here and elsewhere), of the Egyptian numerals, very useful for dental work. For historical pathology the examination of mummies and skeletons is yielding good results. There is little sign of the existence of gout or of syphilitic diseases until late times (see Mummy). A number of papyri have been discovered containing medical prescriptions. The earliest are of the XXIIth Dynasty from Kahun, one being veterinary, the other gastronomical. The finest non-religious papyrus known, the Ebers Papyrus, is a vast collection of receipts. One section, giving us some of "the mysteries of the physician," shows how accurately he knew the usual one was his notion of the constitution of the body. It teaches little more than that the pulse is felt in every part of the body, that there are vessels leading from the heart to the eyes, ears, nose and all the other members, and that "the breath entering the nose goes to the heart and the lungs." The prescriptions are for a great variety of ailments and afflictions—diseases of the eye and the stomach, sores and broken bones, to make the heart strong, the brain work better, and so on. The diuretics are particularly numerous, and the medicines take the form of pills, draughts, liniments, fumigations, &c. The prescriptions are often fanciful and may thus bear some absurd relation to the disease to be cured, but generally they would be to some extent effective. Their action was assisted by spells, for general use in the preparation or application, or for special diseases. In most cases several ingredients are prescribed together: when the amounts are indicated it is by measure not by weight, and evidently no very potent drugs were employed, for the smallest measure specified is equal to about half of a cubic inch. Little has yet been accomplished in identifying the diseases and the substances named in the medical papyri.

II. Astronomy.—The brilliant skies of day and night in Egypt favoured the development of astronomy. A papyrus of the Roman period in the British Museum attributes the invention of horoscopes to the Egyptians, but no early instance is known. Prof. Petrie has indeed suggested, chiefly on chronological grounds, that a table of stars on the ceiling of the Ramessum temple and another in the tomb of Rameses VI. (repeated in that of Rameses IX. without alteration) were horoscopes of Rameses II. and VI.; but Mahler's interpretation of the tables on which this would rest appears to be false. Astronomy played a considerable part in religious matters for fixing the dates of festivals and determining the hours of the night. The titles of several temple books are preserved recording the movements and phases of the sun, moon and stars. The rising of Sothis ( Sirius) was one of the great marks of the time; the year was the important point to fix in the yearly calendar (see below, § "Chronology"). The primitive clock—the temple time-keeper (horoscope), consisting of a ωρολογον καλ φωνα (Clemens Alex. Strom. vi. 4. 35), has been identified with two

1 Formerly transcribed ἀκριν or " heap ", " problems."
2 Cleopatra inscribed in hieroglyphic are found soon after the Macedonian conquest.
of the testimony bearing upon it. For a true appreciation of the chaotic polytheism that reveals itself even in the earliest texts it would be necessary to be able to trace its development, stage by stage, out of a number of naive primitive cults; but the period of growth lies behind recorded history, and we are here reduced to hypotheses and a posteriori reconstructions. The same criticism applies, no doubt, to other religions, like those of Greece and Rome. In Egypt, however, the difficulty is much aggravated by the poor quality of the evidence. The religious books are textually very corrupt, one-sided in their subject-matter, and distributed over a period of more than two thousand years. The greatest defect of all is their relative silence with regard to the myths. For the story of Ias and Osiris we have indeed the late treatise ascribed to Plutarch, and a few fragments of other myths may be culled from earlier native sources. But in general the tales that passed current about the gods are referred to only in mysterious and recondite allusions; as Herodotus for his own times explicitly testifies, a reticence in such matters seems to have been encouraged by the priests.

Thus with regard to Egyptian theology we are very imperfectly informed, and the account that is here given of it must be looked upon as merely provisional. The actual practices of the cult, both funerary and divine, are better known, and we are tolerably familiar with the doctrines as to the future state of the dead. There is good material, too, for the study of Egyptian magic, though this branch has been somewhat neglected hitherto.

2. Main Sources.—(a) The Pyramid texts, a vast collection of incantations inscribed on the inner walls of five royal tombs of the Vth and VIth Dynasties at Sakkātā, discovered and first published by Maspero. Much of these texts is of extreme antiquity; one incantation at least has been proved to belong to an age anterior to the unification of the Northern and Southern kingdoms. Later copies also exist, but possess little independent critical value. The subject-matter is funerary, i.e. it deals with the fate of the dead king in the next life. Some chapters describe the manner in which he passes from earth to heaven and becomes a star in the firmament, others deal with the food and drink necessary for his continued existence after death, and others again with the royal prerogatives which he hopes still to enjoy; many are directed against the bites of snakes and stings of scorpions. It is possible that these incantations were recited as part of the funerary ritual, but there is no doubt that their mere presence in the tombs was supposed to be magically effective for the welfare of the dead. Originally these texts had an application to the king alone, but before the beginning of the XIIth Dynasty private individuals had begun to employ them on their own behalf. They seem to be relatively free from textual corruption, but the vocabulary still occasionally much difficulty to the reader.

(b) The Book of the Dead is the somewhat inappropriate name applied to a large similar collection of texts of various dates, certain chapters of which show a tendency to become welded together into a book of fixed content and uniform order. A number of chapters contained in the later recensions are already found on the sarcophagi of the Middle Kingdom, together with a host of funereal texts not usually reckoned as belonging to the Book of the Dead; these have been published by Lacau. The above-mentioned nucleus, combined with other chapters of more recent origin, is found in the papyri of the XVIIIth-XXth Dynasties, and forms the so-called Theban recension, which has been edited by Naville in an important work. Here already more or less rigid groups of chapters may be noted, but individual manuscripts differ greatly in what they include and exclude. In the Saite period a sort of standard edition was put together, consisting of 18 chapters in a fixed order and bearing a common title "the book of going forth in the day"; this recension was published by Lepsius in 1842 from a Turin papyrus. Like the Pyramid texts, the Book of the Dead served a funerary purpose, but its contents are far more heterogeneous; besides chapters enabling the dead man to assume what shape he will, or to issue triumphal processions from the last judgment, there are lists
of gates to be passed and demons to be encountered in the nether world, formulae such as are inscribed on sepulchral figures and amulets, and even hymns to the sun-god. These texts are for the most part fairly correctly copied with a rapid progress of Pierret, Renouf and Budge, much labour must yet be expended upon them before they can rank as a first-rate source.

(c) The texts of the Tombs of the Kings at Thebes (XVIIIth–XXth Dyn.) consist of a series of theological books compiled at an uncertain date; they have been edited by Naville and Lefèvre. The chief of these, extant in a longer and a shorter version, is called The Book of that which is in the Nether World (familiarly known as the Am Duat) and deals with the journey of the sun during the twelve hours of the night. The Book of Gates treats of the same topic from a more theological standpoint. The Litaniess of the Sun contain the acclamations with which the sun-god Re was greeted, when at eventide his bark reached the entrance of the nether world. Another treatise relates the destruction of mankind, and the circumstances that led to the creation of the heavens in the form of a cow.

(d) Among the later religious books one or two deserve a special mention, such as The Overthrowing of Apep, the serpent enemy of the sun-god; The Lamentations of Isis and Nephthys over their murdered brother Osiris; The Book of Breakings, a favourite book among the later Theban priests. Several of these books were used in the ritual of feast days, but all have received a secondary funerary employment, and are therefore found buried with the dead in their tombs.

(e) The Ritual texts have survived only in copies not earlier than the New Kingdom. The temple ritual employed in the daily cult is illustrated by the scenes depicted on the inner walls of the great temples: the formulae recited during the performance of the ceremonies are recorded at length in the temple of Seti I. (XIXth Dyn.) at Abydos, as well as in some later papyri in Berlin. The whole material has been collected and studied by Moret. The funerary ritual is known from texts in the Theban tombs (XVIIIth–XXth Dyn.) and papyri and sarcophagi of later date; older versions are contained in the Pyramid texts and The Book of the Dead. Schiaparelli has done much towards gathering together this scattered material. The ritual observed during the process of embalment is preserved in late papyri in Paris and Cairo published by Maspero.

(f) The magical documents have been comparatively little studied, in spite of their great interest. They deal for the most part with the healing of diseases, the bites of snakes and scorpions, &c., but incidentally cast many sidelights on the mythology and superstitious beliefs. The best-known of these books is the Papyrus Harris published by F. J. Chabas, but other papyri of as great or greater importance are to be found in the Leiden, Turin and other collections. A curious book published by A. Erman contains spells to be used by mothers for the protection of their children. A papyrus in London contains a calendar of lucky and unlucky days. A late class of stelae, of which the best specimen has been published by Golenischeff, consists of spells of various kinds originally intended for the use of the living, but later employed for funerary purposes.

(g) Under the heading Miscellaneous we must mention a number of sources of great value: the grave-stones, or stelae, especially those from Abydos, which throw much light on funerary beliefs; the great Papyrus Harris, the longest of all papyri, which enumerates the gifts of Re, Amun and other gods to the various temples of Egypt; the hymns to the gods preserved in Cairo and Leiden papyri; and the inscriptions of the Ptolemaic temples (Dendera, Edfu, &c.), which teem with good religious material. Nor can any attempt here be made to summarize the remaining native Egyptian sources, literary and archaeological, that deserve notice.

(4) Among the classical writers, Plutarch in his treatise Concerning Isis and Osiris is the most important. Diodorus also is useful. Herodotus, according to his rigorous way of divulging sacred mysteries, is only a second-rate source.

3. The Gods.—The end of the pre-dynastic period, in which we dimly descry a number of independent tribes in constant warfare with one another, was marked by the rise of a united Egyptian state with a single Phaenorian ruler at its head. The era of peace thus inaugurated brought with it a rapid progress in all branches of civilization; and there soon emerged not only a national art and a condition of material prosperity shared by the entire land in common, but also a state religion, which gathered up the ancient tribal cults and floating cosmical conceptions, and combining them as best it could, imposed them on the people as a whole. By the time that the Pyramid texts were put into writing, doubtless long before the Vth Dynasty, this religion had assumed a stereotypet appearance that clung to it for ever afterwards. But the multitude of the deities and the variety of the myths that it strove to incorporate prevented the development of a uniform theological system, and the heterogeneous origin of the religion remained irrevocably stamped upon its face. Written records were few at the time when the pantheon was built up, so that the process of construction could not be followed historically from stage to stage; but it is possible by arguing backwards from the later facts to discern the main tendencies at work, and the principal elementary cults that served as the materials.

The gods of the pre-dynastic period may be divided into two chief groups, the tribal or local divinities and the cosmic or explanatory deities. At the beginning each tribe had its own particular god, who in essence was nothing but the articulate expression of the inner cohesion and of the outward independence of the tribe itself, but who outwardly manifested himself in the form of some animal or took up his abode in some fetish of wood or stone. In times of peace this visible emblem of the god's presence was housed in a rude shrine, but in war-time it was taken thence and carried into the battlefield on a standard. We find such divine standards often depicted on the earliest monuments, and among the symbols placed upon them may be detected the images of many deities destined to play an important part in the later national pantheon, such as the falcon Horus, the wolf Weepawet (Ophios), the goddess Neith, symbolized by a shield transixed with arrows, and the god Min, the nature of whose fetish is obscure. In course of time the tribes became localized in particular districts, under the influence of a growing central authority, and their gods then passed from tribal into local deities. Hence it came about that the provincial districts or nomes, as they were called, often derived their names from the gods of tribes that settled in them, these names being hieroglyphically written with the sign for 'district,' surmounted by standards of the type above described, e.g. "the name of the dog Anubis," the 17th or Cynopolis nome of Upper Egypt. In this way a large number of deities came to enjoy special reverence in restricted territories, e.g. the ram Khnum in Elephantine, the jerboa or okapi (?), Seth in Ombos, the ibis Thoth in Hermopolis Magna, and of the gods named above, Horus in Hieraconpolis, Weepawet in Assiut, Neith in Sais, and Min in Coptos. As towns and villages gradually sprang up, too, they too adopted as their patron some one or other of the original tribal gods, so that these came to have different seats of worship all over Egypt. For this reason it is often hard to tell where the primitive cult-centre of a particular deity is to be sought; thus Horus seems equally at home both at Buto in the Delta and at Hieraconpolis in Upper Egypt, and the earliest worship of Seth appears to have been claimed no less by Tanis in the north than by Onbros in the south. The localization of gods in many different places was to give them a double aspect; so, for instance, Khnum the god of Elephantine could in one minute be regarded as identical with

Classification of the Egyptian gods.
Khnum the god of Esna, while in the next minute and without any conscious sense of contradiction the two might be looked upon as entirely separate beings. In one it might be no ambiguity as to what divinity was meant, it became usual, in speaking of any local deity, to specify the place of which he was "lord." The tendency to create new forms of a god by instituting his worship in new local centres persisted throughout the whole course of Egyptian history, unhindered by the opposite tendency which made national out of local gods. Some of the cosmic gods, like the sun-god Re of Heliopolis and of Hermontis, early acquired a local in addition to their cosmic aspect.

The innermost principle of their existence, as patrons and protectors of restricted communities, the primitive tribal gods did not differ from one another. But externally they were distinguishable by the various shapes that their worshippers ascribed to them; and there can be little doubt that even in the beginning each had his own special attributes and particular mythical traits. These, however, may have borne little resemblance to the later conceptions of the same gods with which we are made familiar by the Pyramid texts. Thus we have no means of ascertaining what the earliest people of Sais thought about their goddess Neith, though her fetish would seem to point to her warlike nature. Nor are we much wiser in respect of those primitive tribal gods that are represented on the oldest monuments in animal form. For though we may be sure that the shape of an animal was that in which these gods were literally visible to their worshippers, yet it is incredible that one living animal was chosen to be the earthly tenement of the deity, or whether he revealed himself in every individual of a species, or whether merely the cult-image was roughly hewn into the shape of an animal. Not too much weight must be attached to later evidence on this point; for the New Kingdom and still more the Graeco-Roman period witnessed a strange recrudescence of supposed primitive cults, to which they gave a form that may or may not have been historically exact. In some places whole classes of animals came to be deemed sacred. Thus at Bubastis, where the cat-headed Bast (Ubasti) was worshipped, vast cemeteries of mummmified cats have been found; and elsewhere similar funerary cults were accorded to crocodiles, lizards, ibises and many other animals. In Elephantine Khnum was supposed to become incarnate in a ram, at whose death the divinity left him and took up his abode in another. So too the bull ofApis (a black bull with white spots) was regarded as a reincarnation of Ptah, the local god of Memphis, and similarly the Mnevis and Bacis bulls were accounted to be "the living souls" of Etem of Heliopolis and of Re of Hermontis respectively; these latter cults are certainly secondary, for Ptah himself was never, either early or late, depicted otherwise than in human form, as a mummy or as a dwarf; and Etem and Re are but different names of the sun-god. The form of a snake, attributed to many local goddesses, especially in later times (e.g. Mereser of the Theban necropolis), was borrowed from the very ancient deity Oto (Buto); the semblance of a snake became so characteristic of female divinities that even the word "goddess" was written with the hieroglyph of a snake. Other animal shapes particularly affected by goddesses were those of a lioness (Sakhmi, Pakhe) or a cow (Hathor, Isis). The primitive animal gods are not to be confused with the animal forms ascribed to many cosmic deities; thus when the sun-god Re was pictured as a scarabaeus, or dung-beetle, rolling its ball of dung behind it, this was certainly mere poetical imagery. Or else a cosmic god might assume an animal shape through assimilation with some tribal god, as when Re was identified with Horus and therefore depicted as a falcon.

With the advance of civilization and the transformation of the tribal gods into national divinities, the beliefs held about them must have become less crude. At a very early date the anthropomorphizing tendency caused the animal deities to be represented with human bodies, though as a rule they retained their animal heads; so in the case of Seth as early as the IInd Dynasty. The other gods carry their primitive fetishes in their hands (like Neith, who is depicted holding arrows) or on their heads (so Nefertem [Iphthimal] with his lotus-flower). At the same time this evolvement had to accustom us to a number of instances this may have come about by the emphasizing of a really primitive trait; as when the wolf Ophiops, in consonance with the predatory nature of that animal, developed into a god of war. In other cases the transitional steps are shrouded in mystery; we do not know, for example, why the ibis Thoth subsequently became the patron of the fine arts, the inventor of writing, and the scribe of the gods. But the main factor in the occurrence of such transitory phases was undoubtedly the formation of myths, which brought gods of independent origin into relation with one another, and thus imbued them with human passions and virtues. Here dim historic recollections often determined the features of the story, and in one famous legend that knits together a group of gods all seemingly local in origin we can still faintly trace how the tale arose, was added to, and finally crystallized in a coherent form.

Osiris was a wise and beneficent king, who reclaimed the Egyptians from savagery, gave them laws and taught them handicrafts. The prosperous reign of Osiris was brought to a premature close by the machinations of his wicked brother Seth, who, with seventy-two fellow-conspirators invited him to a banquet, induced him to enter a cunningly-wrought coffin made exactly to his measure, then shut down the lid and cast the chest into the Nile. Isis, the faithful wife of Osiris, set forth in search of her dead husband's body, and after long and adventure- fraught wanderings succeeded in getting the body to tell what it knew about Seth's guilt. Then while she was absent visiting her son Horus in the city of Buto, Seth once more gained possession of the corpse, cut it into fourteen pieces, and scattered them all over Egypt. But Isis collected the fragments, and wherever one was found, buried it with due honour; or, according to a different account, she joined the limbs together by virtue of her magical powers, and the slain Osiris, thus resurrected, henceforth reigned as king of the dead in the nether world. When Horus grew up he set out to avenge his father's murder, and after terrible struggles finally conquered and dispossessed his wicked uncle; or, as another version relates, the combatants were separated by Thoth, and Egypt divided between them, the northern part falling to Horus and the southern to Seth. Such is the story as told by Plutarch, with certain additions and modifications from older native sources. There existed, however, a very ancient tradition that Seth and Seth and Seth were hostile brothers, not nephew and uncle; and many considerations may be urged in support of the thesis which regards their struggles as reminiscences of wars between two prominent tribes or confederations of tribes, one of which worshipped the falcon Horus while the other had the okapi (? Seth as its patron and champion. The Horus-tribes were the victors, and it was from them that the dynastic line sprang; hence the Pharaoh always bore the name of Horus, and represented in his own hallowed person the ancient tribal deity. Of Osiris we can only state that he was originally the local god of Busiris, whatever further characteristics he primitively possessed being quite obscure. Isis was perhaps the local goddess of Buto, a town not far distant from Busiris; this geographical proximity would suffice to explain her connection with Osiris in the tale. A legend now arose, we know not how or why, which made Seth the brother and murderer of Osiris; and this led to a fusion of the Horus-Seth and the Seth-Isis Osiris motifs. The relationships had now to be readjusted, and the most popular view recognized Horus as the son and avenger of Osiris. The more ancient account survived, however, in the myth that Osiris, Horus, Seth, Isis and Nephtys (a goddess who plays but a minor part in the Osiris cycle) were all children of the earth-god Keb and the sky-goddess Nut, born on the five consecutive days added on at the end of the year (the so-called epagomenal days). Later generations reconciled these contradictions by assuming the existence of two Horuses, one the brother of Osiris, Seth and Isis, being named Haroeri, i.e. Horus the elder, while the other, the child of Isis and Osiris, was called Harpocrates, i.e. Horus the child.
The second main class of divinities that entered into the composition of the Egyptian pantheon was due to that innate and universal speculative bent which seeks, and never fails to find, an explanation of the facts of the external world. Behind the great natural phenomena that they perceived all around them, the Egyptians, like other primitive folk, postulated the existence of divine wills not dissimilar in their existence to the one superior in the vast universe in which they lived. These were the gods of Egypt. Among these cosmic deities was the sun-god Re, whose supremacy seemed predestined under the cloudless sky of Egypt. The oldest conceptions represented Re as sailing across the heavens in a ship called “Manet,” “the bark of the dawn”; at sunset he stepped aboard another vessel named “Mesenket,” “the bark of the dusk,” which bore him back from west to east during the night. Later theories symbolized Re in many different ways. For some he was identical with Horus, and then he was falcon-headed and was called Hor-akhti, the Horus of the horizon. Others pictured him to themselves as a tiny infant in the early dawn, as full-grown at noon, and as an infirm old man in the evening. When the sky was imagined as a cow, he was a calf born anew every morning. The moon was a male deity, who likewise fared across the heavens in a boat; hence he was often named Chons, “the sailor.” The ibis-god Thoth was early identified with the moon. The stars and planets were likewise gods. Among them the bright star Sirius was held in special esteem; it was a goddess Sothis (Sopdec), often identified by the Egyptians with Isis. The constellations that seemed unceasingly to speed across the sky were named “the never-resting ones,” and the circumpolar stars, which never sink beneath the horizon, were known as “the imperishables.”

Concerning earth and sky there were many different opinions. Some thought that the sky was a goddess Nut, whom the god Shu held aloof from her husband Geb the earth, on whose back the plants and trees grew. Others believed in a celestial ocean, personified under the name of Nun, over which the heavenly bodies sailed in boats. At a later date the sky was held to be a cow (Hathor) whose four feet stood firm upon the soil; or else a vast face, in which the right eye was the sun and the left eye the moon. Alongside these fanciful conceptions there existed a more sober view, according to which the earth was a long oval plain, and the sky an ivory roof supported by the tops of mountains or by four pillars at the cardinal points.

 Beneath the ground lay a dark and mysterious region, now conceived as an inverse heaven (Nenet), now as a vast series of caverns whose gates were guarded by demons. This nether world was known as the Duat (Dat, Té), and through it passed the sun on his journey during the hours of night; there too, as many thought, dwelt the dead and their spirit gods. That this natural feature of Egypt, the Nile, was of course one of the gods; his name was Hapi, and as a sign of his fecundity he had long pendulous breasts like a woman. In contradistinction to the tribal gods, it rarely happened that the cosmic deities enjoyed a cult. But there are a few important exceptions: Re in Heliopolis (here identified with a local god Eton) and in Hermopolis; Hathor at Dendera and elsewhere. Certain of the tribal gods were also identified with cosmic divinities, and the latter thus became the objects of a cult; so, for instance, the Horus of Edfu was a sun-god, and Thoth in Hermopolis Maga was held to be the moon.

An extension of the principle that created the cosmic gods gave rise to a large number of minor deities and demons. Day and night, the year, the seasons, eternity, and many similar conceptions were each represented by a god or goddess. Thus Osiris so early identified with the god of the dead, and his companions, became a shadowy and doubtful existence. Human attributes like Taste, Knowledge, Joy and so forth were likewise personified, no less than abstract ideas such as Fate, Destiny and others; rather more clearly defined than the rest was Maat, the goddess of Truth and Right, who was fabled to be the daughter of Re and may even have had a cult. Certain gods were purely functional, that is to say, they appeared at special times to perform some appointed task, at the completion of which they vanished. Such were Nepri, the god of the corn-harvest; Mekhonit, the goddess who attended every child-bed; Tait, the goddess of weaving. Numberless semi-divine beings had no other purpose than to fill out the myths, as, for instance, the chattering apes that greeted the sun-god Re as he rose above the eastern horizon, and the demons who opened the gates of the Underworld for the ascent of the sun-god. So many were the gods, with Horus as its firstborn, that the Egyptians had to swivel the already overcrowded ranks of the pantheon. Contact with foreign lands brought with it several new deities, Baal, Anat and Resheph from Syria, and the misshapen dwarf Bes from the south; earlier than these, the Astarte of Byblos, whom the Egyptians identified with Hathor. In Thebes Amenophis I, and his spouse Nefertari were worshiped as patron gods of the necropolis many centuries after their death. Two men of exceptional wisdom received divine honors, and had temples of their own in the Ptolemaic period; these were Imouthes, who had lived under Zoser of the IIIrd Dynasty, and Amenophis son of Hapu, a contemporary of the third king of the same name (XVIIIth Dyn.). The hill of Sheikh Abd-el-gurna at Thebes was looked upon as a particularly holy place, and was revered as a goddess. Almost anything that was associated with a god in any object used in the divine ritual could at a given moment be envisaged as a deity. Thus the boat of Osiris (Nemhmet) and those of the sun-god were goddesses; and various wands and scepters belonging to certain gods were imagined as harboring the divine being. Truly it might have been said in ancient Egypt: of the making of gods there is no end!

For such order as can be discerned in the mythological conceptions of the Egyptians the priesthood was largely responsible. At a very early date the theological school of Heliopolis undertook the task of systematizing the gods and the myths, and it is mainly to them that is due the Egyptian religion as we find it in the Pyramid texts. Their influence is particularly conspicuous in the prominent place accorded to the sun-god Re, and in the creation-legend that made him the father of gods and men. First of all living things was Re; legend told how he arose as a naked babe from a lotus-flower that floated on the primeval ocean Nun. Others held the view that he crept from an egg that lay on a hill in the midst of a lake called Desdes; and a third, more barbarous, tale related his obscene act of self-procreation. Re became the father of the pair of gods Shu and Tefnut (Tophenis), who emanated from his spittle. They again gave birth to Geb and Nut, from whom in their turn sprang Osiris and Seth, Isis and Nephthys. These nine gods were together known as the great Ennead or cycle of nine. A second series of nine deities, with Osiris as its central member, was invented at the same time or not long afterwards, and was called the Lesser Ennead. In later times the theory of the Ennead became very popular and was adopted by most of the local priesthoods, who substituted their own favourite god for Re, sometimes retaining and sometimes changing the names of the other eight deities. Thus locally many different gods came to be viewed as the creators of the world. Only in two instances, however, did a local god ever obtain wide acceptance in the capacity of demiurge: Ptah of Memphis, who was famed as an artist and master-builder, and Khnum of Elephantine, who was said to have moulded mankind on the potter's wheel.

Already in the Pyramid texts the importance of Osiris almost rivaled that of Re. His worship does not seem to have been due to Heliopolitan influence, and may possibly have been propagated by active missionary effort. It is apparently through the funerary cult that Osiris came into the homes of the people; for at a very ancient date he was identified with every dead king, and it needed but a slight extension of this idea to make him into a king of the dead. In later times the moral aspect of his tale was doubtless the main cause of its continued popularity; Osiris was named Onnephis, “the good Being” par excellence, and Seth was contrasted with him as the author and the root of all evil. Still the Egyptians themselves seem
to have been somewhat at a loss to account for the great veneration that they paid to Osiris. Successive theories interpreted him as the god of the earth, as the god of the Nile, as a god of vegetation, as a moon-god and as a sun-god; and nearly every one of these theories has been claimed to be the primitive truth by some scholar or another.

Nowhere is the conservatism of the Egyptians more clearly displayed than in the tenacity with which they clung to the old forms of the theology, such as we have essayed to describe. Neither the influx of new deities nor the diligence of the priestly authors and commentators availed to break down the cast-iron traditions with which the compilers of the Pyramid texts were already familiar. It is true that with the displacement of the capital town certain local deities attained a degree of power that, superficially regarded, seems to alter the entire perspective of the religion. Thus Ammon, originally the obscure local god of Thebes, was raised by the Theban monarchs of the XIIth and of the XVIIIth to XXIst Dynasties to a predominant position never equalled by any other divinity; and, by similar means, Suchos of the Fayum, Ubasti of Bubastis, and Neith of Sais, each enjoyed for a short space of time a consideration that no other cause would have secured to them. But precisely the example of Ammon proves the hopelessness of any attempt to change the time-honoured religious creeds, a process which could only have been achieved with the sun-god Re, whose cult-centre was thus merely transferred a few hundred miles to the South. Nor could even the violent religious revolution of Akhenaton (Amenophis IV.), of which we shall later have occasion to speak, sweep away for ever beliefs that had persisted for so many generations.

But if the facts of the religion, broadly viewed, never underwent a change, the interpretation of those facts did so in no small degree. The religious books were for the most part written in archaic language, which was only imperfectly understood by the priests of later times; and hence great scope was given to them to exercise their ingenuity as commentators. By the time of the XVIIIth Dynasty some early chapters of the Book of the Dead had been provided with a triple commentary. Unfortunately the methods pursued were as little reasonable as those adopted by the medieval Jewish Rabbis; instead of the context being studied as a whole, with a view to the recovery of its literal sense, each single verse was considered separately, and explained as an allusion to some obscure myth or as embodying some mystical meaning. Thus so far from simplifying or really elucidating the religion, these priestly labours tended rather to confuse one legend with another and to efface the personality of individual gods. The ease with which one god could be identified with another is perhaps the most striking characteristic of the theology. There are but few of the greatest deities who were not at some time or another identified with the solar god Re. His fusion with Horus and Eton has already been noted; further we find an Amnon-Re, a Sobk-Re, a Khnum-Re; and Month, Onouris, Show and Osiris are all described as possessing the attributes of the sun. Ptab was early assimilated to the sepulchral gods Sokaris and Osiris. Pairs of deities whose personalities are often blended or interchanged are Hathor and Nut, Sakhmi and Pakhe, Seth and Apophis. So too in Abydos, his later home, Osiris was identified with Khante-Amenti (Khtentamenti, Khtentamethes), "the chief of those who are in the West," a name that was given to a vaguely-conceived but widely-venerated divinity ruler of the dead. Many factors helped in the process of assimilation. The unity of the state was largely influential in bringing about the suppression of local differences of belief. The less important priesthoods were glad to enhance the reputation of the deity they served by identifying him with some more important god. And the mystical bent of the Egyptians found satisfaction in the multiplicity of forms that their gods could assume; among the favourite epithets which the hymns apply to deities are such as "mysterious of shapes," "multiple of faces."

The goal towards which these tendencies verged was monotheism; and though this goal was only once, and then quite ephemerally, reached, still the monotheistic idea was at most periods, so to speak, in the air. Sometimes the qualities common to all the gods were abstracted, and the resultant notion spoken of as "the god." At other times, and especially in the hymns addressed to some divinity, all other gods were momentarily forgotten, and he was eulogized as "the only one," "the supreme," and so forth. While several of the chief deities were consciously combined and regarded as different emanations or aspects of a Sole Being; thus a Ramesside hymn begins with the words "Three are all the gods, Ammon, Re and Ptab," and then it is shown how these three gods, each in his own particular way, gave expression and effect to a single divine purpose.

For a brief period at the end of the XVIIIth Dynasty a real monotheism, as exclusive as that of Judaism or of Islam, was attempted as the state religion of Egypt. The young Pharaoh Amenophis IV. seems to have been fired by genuine fanatical enthusiasm, though political motives, as well as doctrinal considerations, may have prompted him in the planning of his religious revolution (see also § History). The Theban god Ammon-Re was then supreme, and the ever-growing power of his priesthood may well have inflamed the jealousy of their Helipolitan rivals. Amenophis began his reign in Thebes as an adherent of the traditional faith, but after a few years he abandoned that town and built a new capital for his god Aton 200 m. farther north, at a place now called El Amarna. The new deity was a personification of the sun's disk. The name Re was suppressed, as too intimately associated with that of Ammon; and Ammon, together with all the other gods, was put to the ban. Amenophis even changed his own name, of which the name of Ammon formed an element, to Akhenaton, "the brilliance of the Aton," and the capital was called Khitaton, "The Horizon of the Aton." The new dogmas were known as "the Teaching," and their tenets, as revealed in the poems composed in honour of the Aton, breathe the purest and most exalted monotheistic spirit. The movement had, no doubt, met with serious opposition from the very start, and the reaction soon set in. The immediate successors of Akhenaton strove to follow in his footsteps, but the conservative nature of Egypt quickly asserted itself. Not sixty years after the accession of Akhenaton, his city was abandoned, its rulers branded as heretics, and the old religion restored in Thebes as completely as if the Aton had never existed.

Having thus failed to become rational, Egyptian theology took refuge in learning. The need for a more spiritual and intellectual interpretation of the pantheon still remained, and gave rise to a number of theological sciences. The names of the gods and the places of their worship were catalogued and classified, with reference to the topography of mythological regions. Much ingenuity was expended on the development of a history of the gods, the groundwork of which had been laid in much earlier times. Re was not only the creator of the world, but he was also the first king of Egypt. He was followed on the throne by the other eight members of his Ennead, then by the lesser Ennead and by other gods, and finally by the so-called "worshippers of Horus." The latter were not wholly mythical personages, though they were regarded as demigods (Manetho calls them "the dead, [mistoria]); they have been shown to be none other than the dim rulers of the predynastic age. The Pharaohs of the historic period were thus divine, not only by virtue of their connexion with Horus (see above), but also as descendants of Re; and the king of Egypt was called "the good god" during his lifetime, and "the great god" after his death. The later religious literature is much taken up with the mythical and demi-mythical dynasties of kings, and the priests compiled, with many newly-invented details, the chronicles of the wars they were supposed to have waged.

In a similar manner, the ethical and allegorical methods of interpretation came into much greater prominence towards the end of the New Kingdom. The Osiran legend, as we have already seen, was early accepted as symbolizing the conflict between good and evil. So too the victories of Re over the serpent named Apophis were more or less clearly understood as a simile of
the antithetical nature of light and darkness. In one text at least as ancient as the XVIIIth Dynasty (the copy that we have dates only from the Ethiopian period) an ingenious attempt is made to represent Pht as the source of all life: from him, it is said, emanated Horus as "heart" or "mind" and Thoth as "tongue," and through the conjoint action of these two, the mind conceiving the design and the tongue uttering the creative command, all gods and men and beasts obtained their being. Of this kind of speculation much more must have existed than has reached us. It is done with a simplicity and purity of thought which the Greeks had no view when they praised the wisdom of the ancient Egyptians; and in the classical period similar semi-philosophical interpretations altogether supplanted, among the learned at least, the naive literal beliefs of earlier times. Plutarch in his treatise on Isis and Osiris well exemplifies this standpoint: for him every god and every rite is symbolic of some natural or moral truth.

The final stages of the Egyptian religion are marked by a renewed popularity of all its more barbarous elements. Despairing, as it would seem, of discovering the higher wisdom that the more philosophic of the priests supposed that religion to conceal, the simpler-minded sought to work out their own salvation by restoring the worship of the gods to its most primitive forms. Hence came the fanatical revival of animal-worship which led to the feud and bloodshed between neighbouring towns—a feature of Egyptian religion that at once amused and scandalized contemporary Greek and Latin authors (Plut. De Iside, 72; Juv. xv. 53). Merneptah, who came to the throne about B.C. 1225, found welcome acceptance on European soil; and the shrines of Egyptian deities were established in all the great cities of the Roman Empire. Serapis was a god imported by the first Ptolemy from Sinope on the Black Sea, who soon lost his own identity by assimilation with Osiris-Apis, the bull revered in Memphis. Far down into the Roman age the worship of Serapis persisted and flourished, and it was only when the Serapeum of Alexandria was razed to the ground by order of Theodosius the Great (A.D. 391) that the death-blow of the old Egyptian religion was struck.

Notes are here added on some divinities who have received inadequate or no attention in the preceding pages. For information as to Ammon, Anubis,Apis, Bes,Bubastis,Buto,Isis and Thoth, reference must be made to the special articles on these deities. Aheraios, in Egyptian Harakhte, "he who is upon his lake," the ram-headed god of Hermopolis Magna, gained an ephemeral importance during the XIXth Dynasty, which arose from his town, Oxyrhynchus. Khnum. It is well known about this god, who is seldom mentioned. The burial-place of his priests in later times was in 1904 discovered at Abusir el Meleq. The temple travels by boat, which was often a mere epithet of the moon-god ith or Thoth, is chiefly familiar as the third member of the Thb triad. As such he is represented as a youthful god, wearing a skull-cap surmounted by the moon. His cult was revived and became popular in Ptolemaic times. A curious story about the sending of his statue to Mesopotamia to heal a daughter of the king of Baktan is related upon a stele that purports to date from the Ramessean period: it has been proved to be a pious fraud invented by the priests not earlier than the Greek period. Hathor, whose name means "house of Horus," was at all times a goddess of beauty. She is depicted as a cow or with a human countenance, the cow's ears just showing from under a massive wig. Probably at first a goddess of the sky, she is early mentioned in connection with Re. Later she was often identified with the great goddess of Heliopolis, whose domain was the night and the darkness. Unlike most cosmic deities, she was worshipped in many localities, chief among which was Dendera, where her magnificent temple, of Ptolemaic date, still stands. "The seven Hathors" is a name given to certain fairies, who appeared shortly after the birth of an infant, and predicted his future. Memphite Hathor, whose princedom was the place of worship was the island of Elephantine (there associated with Satis and Anukis), but also revered elsewhere, e.g. together with Nebthu in Eana. He enjoyed great repute as a creator, and was supposed to use the potter's wheel for the purpose. In this capacity he is sometimes accompanied by the frog-headed goddess Hektet. Mont, a hawk-headed god of the Thebaid: in Thebes itself his cult was prominent in the month of Akhet, the ninth month of the year. He was often depicted as a rider upon the sacred donkey, and was credited as a great warrior.

Mix, the god of Coptos and Panopolis (Akhmim), seems to have been early looked upon as a deity of the harvest and crops. His cult dates from the earliest times. Represented as ithyphallic, with two tall plumes on his head, the right arm usually holds a sceptre. In old times he is identified with Horus: later Ammon was confused with him, and depicted in his image. Nefertum (Nehbti, Neftary, the netherness of El Kab), called Eleuthyia by the Greeks. She gained an ascendency as patroness of the south at the time when the two kingdoms were divided as in the mastery. It is as such, in opposition to Buto the goddess of the north, that she is often named on the coins of Egypt. Neith, the very ancient and important goddess of Sais, the Greek Athene. On the earliest monuments she is represented by a shield and two arrows. Later she wears the crown of Lower Egypt, and carries in her hands a bow and arrows, a sign of her warlike character. In the XXVth Dynasty, when a line of Pharaos sprang from Sais, she regained her prominence. She was given many cosmogonic attributes, including the title of mother of Re.

Nephthys, the sister of Osiris and wife of Seth, daughter of Keb and Nut, plays a considerable role in the Osiris story. She sided with Isis and aided her to bring Osiris back to life. Isis and Nephthys are often mentioned together as protectresses of the dead. Onouris, Egyptian En-fu-eri, "sky-bearer," the god of Thinis. Later identified with Shu (Space), who holds heaven and earth apart. Pth, the Hephaestus of the Greeks, a demigurl and creative god, special patron of hand-workers and artisans. Worshipped in Memphis, he perhaps owed his importance more to the political prominence of that town than to anything else. He was early identified with an ancient but obscure god Tenen, and further with the sepulchral deity Sokaris. He is represented either as a closely bearded figure whose hands grasping a sacrificial knife was on the whole standing on a pedestal within a shrine; or else as a misshapen dwarf.

Sekhmet, a lion-headed goddess of war and strife, whose name signifies the mighty. She was worshipped at Latopolis (Esna), but also at a late date as a member of the Memphite triad, with Pth as husband and Neferetem (Iphthimis) as son: often, too, confounded with Banes.

Seth (Egyptian Set, Seti or Sis), by the Greeks called Typhon, was depicted as an animal that has been compared with the jerboa by some, and with the okapi by others, but which the Egyptians themselves occasionally conceived to be nothing but a badly drawn ass. In historic times his cult was celebrated at Tanis. He reigns over a certain prestige as god of the Hades, the rulers, and two Pharaohs of the XIXth Dynasty derived their name Sethos (Seti) from him. But, generally speaking, he was abomina ted as a power of evil, and his figure was often obliterated on the monuments. He is named in similes as a great warrior, and as such and son of Nut he is identified with the Syrian Baal.

4. The Divine Cult.—In the midst of every town rose the temple of the local god, a stately building of stone, strongly contrasting with the mud and plaster houses in which even the wealthiest Egyptians dwelt. It was called the "house of the god" ( ), and in it the deity was supposed to reside, attended by his "servants" ( ). The priests. There was indeed a certain justification for this contention, even when a contrary theory assigned to the divinity a place in the sky, as in the case of the lunar divinity Thoth; for in the inmost sanctuary stood a statue of the god, which served as his representative for the purposes of the cult. Originally each temple was dedicated to one god only; but it early became usual to associate with him a mate of the opposite sex, besides a third deity who might be represented either as a second wife or as a child. As examples of such triads, as they are called, may be mentioned that of Thebes, consisting of Ammon, Mut and Chons, father, mother and child; and as typical of the other kind, where a god was accompanied by two goddesses, that of Elephantine, consisting of Khnum, Satis and Anukis. The needs of the god were much the same as those of men; no more than food and drink, clothes for his apparel, ointment for his limbs, and music and dancing to rejoice his heart. The only difference was that the divine statue was half-consciously recognized as a lifeless thing that required carefully regulated rites and ceremonies to enable it to enjoy the good things offered to it. Early every morning the officiating priest proceeded to the holy of holies, after the preliminaries of purification had cleansed him from any impurity that might interfere with the efficacy of the rites. Then with the prescribed gestures, and reciting appropriate formulae all the while, he broke the seal upon the door of the shrine, loosed the bolts, and at last stood face to face with the
god. There followed a series of prostrations and adorations, culminating in the offering of a small image of Maat, the goddess of truth, or of Maat in the form of Manet, to hand to the god. The last part of the service was the giving of the water and keeping of the oasth. The god was now seated in his open temple, where the priest lit the small shrines with his altar. The god then was adored by the priests, who sang hymns and prayers.

The priests then proceeded to the temple of Osiris, with the god being carried on the shoulders of the priest, who was the high priest of the temple. The priests were dressed in white garments, and carried the god in a large golden casket.

As the priests entered the temple, they were greeted by the sound of music and the chant of the priests. The temple was filled with the sound of the priests singing the hymns of Osiris, the god of the dead, who was believed to be the god of the afterlife.

The priests then proceeded to the chamber where the god was kept, and began the ceremony of adoration and the offering of the water. The priests were then given the task of lighting the shrines with the altar, and singing the hymns of Osiris.

The ceremony lasted for several hours, and the priests were exhausted by the time they were finished. But they knew that this was an important ceremony, and that it was a way of honoring the gods and the dead.

As the ceremony came to an end, the priests offered their prayers and blessings to the gods, and then went to the temple to continue their duties. The temples of Osiris were a place of great importance to the ancient Egyptians, and they were a place where the gods were honored and adored.

5. The Dead and their Cult. — While the worship of the gods
tended more and more to become a monopoly of the state and the priests, and provided no adequate outlet for the religious cravings of the people themselves, this deficiency was amply supplied by the care which they bestowed upon their dead: the Egyptians stand alone among the nations of the world in the elaborate precautions which they took to secure their own welfare beyond the tomb. The belief in immortality, or perhaps rather the incapacity to grasp the notion of complete annihilation, is traceable from the very earliest times: the simplest graves of the prehistoric period, when the corpses were committed to the earth in sheepskins and reed mats, seldom lack at least a few poor vases or articles of toilet for use in the hereafter. In proportion as the prosperity of the land increased, and the advance of civilization afforded the technical means, so did these primitive furnaces give place to a more laborious, and perhaps to a more laudable, funerary equipment. Tombs of brick with a single chamber were succeeded by tombs of stone with several chambers, until they really merited the name of "houses of eternity" that the Egyptians gave to them. The conception of the tomb as the residence of the dead is the fundamental notion that underlies all the ritual observances in connexion with the dead, just as the idea of the temple as the dwelling-place of the god is the basis of the divine cult. The parallelism between the attitude of the Egyptians towards the dead and their attitude towards the god is so striking that it ought never to be lost sight of: nothing can illustrate it better than the manner in which the Osirian doctrines came to permeate both kinds of cult.

The general scheme of Egyptian tombs remained the same throughout the whole of the dynastic period, though there were many variations of detail. By preference they were built in the Western desert, the Amunet, near the place where the sun was seen to go to rest, and which seemed the natural entrance to the nether world. A deep pit led down to the sepulchral chamber where the dead man was deposited amid the funerary furniture destined for his use; and no device was neglected that might enable him to rest here undisturbed. This aim is particularly conspicuous in the pyramids, the gigantic tombs which the Pharaohs of the Old Kingdom constructed for themselves: the passages that lead to the burial chamber were barred at intervals by vast granite blocks, and the narrow opening that gave access to them was hidden from view beneath the stone casing of the pyramid sides. Quite separate from this part of the tomb lay the rooms employed for the cult of the dead: their walls were often adorned with pictures from the earthly life of the deceased, which it was hoped he might still continue to enjoy after death. The innermost chamber was the chapel proper: on its western side was sculptured an imitation door for the rich to have their bodies embalmed. The livers were removed and placed in four vases (the so-called Canopic jars) in which they were supposed to enjoy the protection of the four sons of Horus, the man-headed Mesti, the ape-headed Hapi, the jackal Dammutef and the falcon Khabsenuf. The corpse was treated with natron and asphalt, and wound in a copious swathing of linen bandage, with a mask of linen and stucco on the face. The "mummy" thus prepared was then laid on its side like a sleeper, the head supported by a slab of bone, in a gilded case, and wrapped in a shroud. The operations in connexion with the mummy grow more and more elaborate towards the end of the Pharaonic period: already in the New Kingdom the wealthiest persons had their mummies laid in several coffins, each of which was gaudily painted with mythological scenes and inscriptions. The costliest process of embalment lasted no less than seventy days. Many superstitious rites had to be observed in the course of the process:

a late book has preserved to us the magical formulae that were repeated by the wise kher-heb priest (who in the necropolis performed the functions of tarichetehet, "embalmer"), as each bandage was applied.

A large number of utensils, articles of furniture and the like were placed in the burial-chamber for the use of the dead—jars, weapons, mirrors, and even chairs, musical instruments and wigs. In the early times statues of servants, representing them as engaged in their various functions (brewers, bakers, &c.), were included for the same purpose; they were supposed to perform their menial functions for their deceased lord in the future life. In the Middle Kingdom these are gradually replaced by small models of the mummy itself, and the belief arose that when their owner was called upon to perform any distasteful work in the other world, they would answer to his name and do the task for him. The later isekhet-figures, little statuettes of wood, stone or faience, of which several hundreds are often found in a single tomb, are confused survivals of both of the earlier classes of statuettes. Still more important than all such funerary objects are the books that were placed in the grave for the use of the dead: in the pyramids they are written on the walls of the sepulchral chamber and the passages leading to it; in the Middle Kingdom usually inscribed on the inner sides of the sarcophagi, sometimes contained in rolls of papyrus. The Pyramid texts and the Book of the Dead are the most important of these, and teach us much about the dangers and needs that attended the dead man beyond the tomb, and about the manner in which it was thought they could be counteracted.

The burial ceremony itself must have been an imposing spectacle. In many cases the mummy had to be conveyed across the Nile, and boats were gaily decked out for this purpose. On the western bank a stately procession conducted the deceased to his last resting-place. At the door of the tomb the final ceremonies were performed; they demanded a considerable number of actors, chief among whom were the sem-priest and the kher-heb priest. It was a veritable drama that was here enacted, and recalled in its incidents the story of Osiris, the divine prototype of all successive generations of the Egyptian dead.

However carefully the preliminary rites of embalment and burial might have been performed, however sumptuous the tomb wherein the dead man reposed, he was nevertheless almost entirely at the mercy of the living for his welfare in the other world: he was as dependent on a continued cult on the part of the surviving members of his family as the gods were dependent on the constant attendance of their priests. That portion of a man's individuality which required, in others, the exercise of the senses, and the satisfaction of sensuous needs, was called by the Egyptians the ka, and represented in hieroglyphs by the uplifted hands \textit{[J]}$. This ka was supposed to be born together with the person to whom it belonged, and on the very rare occasions when it is depicted, wears his exact semblance. The conception of this psychical entity is too vaguely formulated by the Egyptians and too foreign to modern thought to admit of exact translation: of the many renderings that have been proposed, perhaps "double" is the most suitable. At all events the ka has to be distinguished from the soul, the bai (in hieroglyphs \textit{[or]} or \textit{[or]}), which was of more tangible nature, and might be described hovering around the tomb in the form of a bird or in some other shape; for it was thought that the soul might assume what shape it would, if the funerary rites had been done to it according to the law. The gods had their ka and bai, and the forms attributed to the latter require more than a mere explanation. The soul of the sky Nun is Re, that of Osiris the Goat of Mendes, the souls of Sobek are crocodiles, and those "of all the gods are snakes"; similarly the soul of Ptah was thought to dwell in the Apis bull, so that each successive Apis was during its lifetime the reincarnation of the god. Other parts of a man's being to which at given moments and in particular contexts the Egyptians assigned a certain degree of separate existence are the "name".
It was, however, the "Ka" alone to which the cult of the dead was directly addressed. This cult was a positive duty binding on the children of a dead man, and doubtless as a rule discharged by them with some regularity and conscientiousness; at least, on the thirty days offerings would be brought to the tomb, and the ceremonies of purification and opening the mouth of the deceased would be enacted. But there could be little guarantee that later generations would perpetuate the cult. It therefore became usual under the Old Kingdom for the wealthiest persons to make testamentary dispositions by which certain other persons agreed for a consideration to observe the required rites at stated periods: they received the name of "servants of the ka," and stood in the same relation to the deceased as the priests to the gods. Or again, contracts might be made with a neighbouring temple, the priesthood of which bound itself to reserve for the contracting party some portion of the offerings that had already been used for the divine cult. There is probably a superstitious reason for the preference shown by the dead for offerings of this kind; no wish is commoner than that one may receive "bread and beer that had gone up to the altar of the local god," or "with whose god had been sated," something of the divine sanctity still clung about such offerings and made them particularly desirable. In spite of all the precautions they took and the contracts they made, the Egyptians could never quite rid themselves of the dread that their tombs might decay and their cult be neglected; and they sought therefore to obtain by prayers and threats what they feared they might lose altogether. The occasional visitor to the tomb is reminded by its inscriptions of the many virtues of the dead man while he yet lived, and is charged, if he be come with empty hands, at least to pronounce the funerary formula; it will indeed cost him nothing but "the breath of his mouth!"

Against the would-be desecrator the wrath of the gods is invoked: "with him shall the great god reckon there where a reckoning is made."

The funerary customs that have been described are meaningless except on the supposition that the tomb was the regular dwelling-place of the dead. But just as the Egyptians found no contradiction between the dual nature of the god and the conception of him as a cosmic deity, so too they often attributed to the dead a continued existence quite apart from the tomb. According to a widely-spread doctrine of great age the deceased Egyptian was translated to the heavens, where he lived on in the form of a star. This theme is elaborated with great detail in the Pyramid texts, where it is the dead king to whom this destiny is promised. It was perhaps only a restricted aristocracy who could aspire to such high honour: the ḫḥk, or "glorified being," who has his place in the sky seems often to hold an intermediate position between the gods and the rank and file of the dead. But in a few early passages the required qualification appears to be rather moral integrity than allotted station. The life of the dead man in the sky is variously envisaged in different texts: at one moment he is spoken of as accompanying the sun-god in his celestial bark, at another as a mighty king more powerful than Re himself; the crudest fancy of all pictures him as a hunter who catches the stars and gods, and cooks and eats them. According to another conception that persisted in the imagination of the Egyptians longer than any of the ideas just mentioned, the home of the dead in the heavens was a fertile region not very far from Egypt itself, intersected by canals and abounding in corn and fruit; this place was called the Sokhet Earu or "field of Reeds."

Even in the oldest texts these beliefs are blended inextricably with the Osiran doctrines. It is not so much as king of the dead that Osiris here appears, but every deceased Egyptian was regarded as himself an Osiris, as having undergone all the indignities inflicted upon the god, but finally triumphant over the powers of death and evil impersonated by Seth. This notion became so popular, that beside it all other views of the dead sink into insignificance; it permeates the funerary cult in all its stages, and from the Middle Kingdom onwards the dead man is regularly called "the Osiris so-and-so," just as though he were completely identical with the god. One presentiment, therefore, was gained a deep ethical meaning in connexion with the dead. It was related how Seth had brought an accusation against Osiris in the great judgment hall of Heliopolis, and how the latter, helped by the skilful speaker Thoth, had emerged from the ordeal acquitted and triumphant. The belief gradually grew up that every dead man would have to face a similar trial before he could be admitted to a life of bliss in the other world. A well-known vignette in the Book of the Dead depicts the scene. In a shrine sits Osiris, the ruler and judge of the dead, accompanied by forty-two assessors; and before him stands the balance on which the heart of the deceased man is to be weighed against Truth; Thoth stands behind and registers the result. The words that accompany this picture are still more remarkable: they form a long negative confession, in which the dead man declares that he has sinned neither against man nor against the gods. Not all the sins named are equally heinous according to modern conceptions; many of them deal with petty offences against religious usages that seem to us but trifling. But it is clear that by the time this chapter was penned it was believed that no man could attain to happiness in the hereafter if he had not been upright, just and charitable in his earthly existence. The date at which these conceptions became general is not quite certain, but it can hardly be later than the Middle Kingdom, when the dead man has the epithet "justified" appended to his name in the inscriptions of his tomb. It was but a natural wish on the part of the Egyptians that they should desire to place their tombs near the traditional burying-place of Osiris. By the time of the XIIth Dynasty it was thought that this lay in Abydos, the town where the kings of the earliest times had been interred. But it was only in a few cases that such a wish could be literally fulfilled. It therefore became customary for those who possessed the means to dedicate at least a tombstone in the neighbourhood of "the staircase of the great god," as the sacred spot was called. And those who had found occasion to visit Abydos in their lifetime took pleasure in recalling the part that they had there taken in the ceremonies of Osiris. Such pilgrims doubtless believed that the pious act would stand to their credit when the day of death arrived.

6. Magic.—Among the rites that were celebrated in the temples or before the statues of the dead were many the mystical meaning of which was but imperfectly understood, though their efficacy was never doubted. Magic was but natural that the Egyptians should wish to employ magic for their own benefit or self-gratification, and since religion put no veto on the practice so long as it was exercised within legal bounds, it was put to a widespread use among them. When magicians made figures of wax representing men whom they desired to injure, this was of course an illegal act like any other, and the law stepped in to prevent it: one papyrus that has been preserved records the judicial proceedings taken in cases of this kind in connexion with the harem conspiracy against Ramesses III.

One of the chief purposes for which magic was employed was to avert diseases. Among the Egyptians, as in other lands, illnesses were supposed to be due to evil spirits or the ghosts of dead men who had taken up their abode in the body of the sufferer, and they could only be driven thence by charms and spells. But out of these primitive notions arose a real medical
ANCIENT LANGUAGE

EGYPT

science: when the ailment could be located and its nature
roughly determined, a more materialistic view was taken of it;
and many herbs and drugs that were originally used for some
superstitious reason, when once they had been found to be actually
effective, easily lost their magical significance and were looked
upon as natural specifics. It is extremely hard to draw any fixed
lines between magic and medicine; but it is curious to note that
simple diagnoses and prescriptions were employed for the
more curable diseases, while magical formulae and amulets
are reserved for those that are harder to cope with, such as the
bites of snakes and the stings of scorpions.

The formulae recited for such purposes are not purely cabalistic,
though inasmuch as mystery is of the very essence of magic,
foreign words and outlookish names occur in them by preference.
Often the magician recites the names of a magical case when a god
had been afflicted with a disease similar to that of the patient,
but had finally recovered: a number of such tales were told of
Horus, who was usually healed by some device of his mother
Isis, she being accounted as a great enchantress. The mere
recitation of such similar cases with their happy issue was
supposed to be magically effective; for almost unlimited power
was supposed to be inherent in mere words. Often the demon is
directly invoked, and commanded to come forth. At other times
the magician relates with particular significance was attributed to
certain numbers: a sevenfold knot, for example, was more
efficacious than others. Often the formula was written on a
strip of papyrus or a scrap of papyrus and tied round the neck of the
person for whom it was intended. Beads and all kinds of
amulets could be infused with magical power so as to be potent
phylacteries to those who wore them.

In conclusion, it must be emphasized that in Egypt magic
stands in no contrast or opposition to religion, at least as long
as it was legitimately used. The religious rites and ceremonies
are full of it. When a pretense was made of opening, with an
iron instrument, the mouth of the divine statue, to the accom-
paniment of recited formulae, this can hardly be termed anything
but magic. Similarly, the potency attributed to ushabti-figures
and the copies of the Book of the Dead deposited in the tombs
is magical in quality. What has been considered under this
heading, however, is the use that the same principles of magic
were put to by men in their own practical life and for their own
advantage.

AUTHORITIES.—An excellent list of books and articles on the
various topics connected with Egyptian Religion will be found in
H. O. Lang's article on the subject in P.D. Chantepie de la Saussaye,
Lehrbuch der Religionsgeschichte (Tübingen, 1905), vol. i. pp. 172
245. Among general works may be especially recommended
A. Ermann, Die ägyptische Religion (Berlin, 1905); and chapters 2
and 3 in C. Maspero, Histoire ancienne des peuples de l'Orient, les

D. EGYPTIAN LANGUAGE AND WRITING.—Decipherment.—

Although attempts were made to read Egyptian hiero-
glyphics so far back as the 17th century, no promise of success
appeared until the discovery of the Rosetta stone in 1799
by the French engineers attached to Napoleon's expedition to
Egypt. This tablet was inscribed with three versions,
in hieroglyphic, demotic and Greek, of a long decree of the
Egyptian monarch Ptolemy V. It was known as the Rosetta
stone.

The Greek and demotic versions were still
almost perfect, but most of the hieroglyphic text had been
broken away with the top of the tablet; portions of about half
of the lines remained, but no single line was complete. In 1802
J. D. Akerblad, a Swedish orientalist attached to the embassy
in Paris, identified the proper names of persons which occurred
in the demotic text, being guided to them by the position of
their equivalents in the Greek. These names, all of them foreign,
were written in an alphabet of a limited number of characters,
and were therefore analysed with comparative ease.

The hieroglyphic text upon the Rosetta stone was too frag-
mentary to furnish of itself the key to the decipherment. But
the study of this with the other scatty monuments and imperfect
records of the demotic and of the Greek has enabled the celebrated
physician Thomas Young (1773-1829) to make a beginning.
In an article completed in 1790 and printed (over the initials
I. J.) in the supplement to the 4th, 5th and 6th editions of the
Encyclopaedia Britannica (vol. iv., 1824), he published a brief
account of Egyptian research, with five plates containing the
rudiments of an Egyptian vocabulary. It appears that Young
could place the hieroglyphic, demotic and Greek texts of the
Rosetta stone very correctly parallel, but he could not accura-
ately break up the Egyptian sentences into words, much less
could he attribute to the words their proper sounds. Yet he
recognized correctly the names of Apis and Re, with many
for words such as "assembly," "good," "name," and
important signs such as those which distinguish feminine words.

In a bad copy of another monument he rightly guessed the royal
name of Berenice in its cartouche by the side of that of Ptolemy
which was already known from its occurrence on the Rosetta
stone. He considered that these names must be written in
phonetic characters in the hieroglyphic as in demotic, but he failed
to analyse them correctly. It was clear, however, that
with more materials and perseverance such efforts after decipher-
ment must eventually succeed.

Meanwhile J. F. Champollion "le Jeune" (see CHAMPOLLION;
and Hartleben, Champollion, sein Leben und sein Werk, Berlin,
1906) had devoted his energies whole-heartedly since 1802,
when he was only eleven years old, to preparing himself for the
solution of the Egyptian problem, by wide linguistic and historical
studies, and above all by familiarising himself with every scrap of
Egyptian writing which he could find. By 1818 he made many
equations between the demotic and the hieroglyphic characters,
and was able to transcribe the demotic names of Ptolemy
and Cleopatra into hieroglyphics. At length, in January 1822,
a copy of the hieroglyphic inscription on the Bankes obelisk,
which had long been fruitlessly in the hands of Young, reached
the French savant. On the base of this obelisk was engraved a
Greek inscription in honour of Ptolemy Euergetes II. and
Cleopatra; of the two cartouches on the obelisk one was of
Ptolemy, the other was easily recognised as that of Cleopatra,
spelt nearly as in Champollion's experimental transcript of the
demotic name, only more fully. This discovery, and the recog-
nition of the name Alexander, gave fourteen alphabetic signs,
including homophones, with ascertained values. Starting from
those, by the beginning of September Champollion had analysed
a long series of Ptolemaic and Roman cartouches. His next
triumph was on the 14th of September, when he read the names
of the ancient Pharaohs Rameses and Tuthmosis in some drawings
just arrived from Egypt, proving that his alphabetic characters
were employed, in conjunction with syllabic signs, for spelling
native names; this gave him the assurance that his discovery
touched the essential nature of the Egyptian writing and not
merely had been a conjecture, a special cipher for the foreign
words which might be quite inapplicable to the rest of the
inscriptions. His progress continued unchecked, and before the
end of the year the connexion of ancient Egyptian and
Coptic was clearly established. Subsequently visits to the
museums of Italy and an expedition to Egypt in 1828-1829
furnished Champollion with ample materials. The Prots du système
hieroglyphique (1st ed. 1823, 2nd ed. 1828) contained the philo-
logical results of his discoveries, and set the correct key to the
Egyptian tongue. But his MS. collections were vast, and his illness
after the strenuous labours of the expedition and his early death in 1832
left all in confusion. The Grammaire égyptienne and Dictionnaire
égyptien, edited from these MSS. by his brother, precious as they
were, must be a very imperfect register of the height of his
attainments. In his last years he was able to translate long
texts in hieroglyphic and in hieratic of the New Kingdom and
of the later periods with some accuracy, and his comprehension of demotic was considerable. Champollion outdistanced all his competitors from the first, and had practically nothing to thank them for except material to work on, and too often that had been intentionally withheld from him. In eleven years he broke ground in all directions; if the ordinary span of life had been allowed him, with twenty or thirty more years of labor he might have brought order into the chaos of different ages and styles of language and writing; but, as it was, the task of co-ordination remained to be done by others. For one year, before his illness incapacitated him, Champollion held a professorship in Paris; but of his pupils and fellow-workers, F. P. Salvolini, insincere and self-seeking, died young, and Ippolito Rosellini (1800-1843) showed little original power. From 1832 to 1837 there was a pause in the researches. It seemed as if the young science might be overwhelmed by the storm of doubts and detraction that was poured upon it by the enemies of Champollion. Then, however, Lepsius in Germany and Samuel Birch in England took up the thread where the master had dropped it, and E. de Rougé, H. Brugsch, François Joseph Chabas and a number of lesser lights quickly followed. Brugsch (q.v.) was the author of a hieroglyphic and demotic dictionary which still holds the field, and he carried forward the study of demotic by a giant's stride. De Rougé (d. 1872) in France was a great translator of hieroglyphic texts and the author of an important grammatical work. Chabas (1817-1882) especially addressed himself to the reading of the hieratic texts of the New Kingdom. By such labors after forty years the results attained by Champollion in decipherment were entirely superseded. Yet, while the values of the signs were for the most part well ascertained, and the meanings of most works fixed with some degree of accuracy, few grammatical rules had as yet been established, the varieties of the language at different periods had not been defined, and the origins of the hieroglyphs and of their values had not been investigated beyond the most obvious points. At this time a rare translator of Egyptian texts in all branches was arising in G. Maspero (q.v.), while E. Revillout addressed himself with success to the task of interpreting the legal documents of demotic which had been almost entirely neglected for thirty years. But the honour of inaugurating an epoch marked by greater precision belongs to Germany. The study of Coptic had been inaugurated in Europe early in the 17th century, and reached a high level in the work of the Dane Georg Zoega (1755-1800) at the end of the 18th century. In 1835, too, late for Champollion to use it, Amadeo Peyron (1785-1870) of Turin published a Coptic lexicon of great merit which is still standard, though far from satisfying the demands of scholars of the present day. In 1836 Landoldt and Bott (Koptische Grammatik) admirably studied the grammatical forms of Coptic. The much more difficult task of recovering the grammar of Egyptian has occupied thirty years of special study by Adolf Erman and his school at Berlin, and has now reached an advanced stage. The greater part of Egyptian texts after the Middle Kingdom having been written in what was even then practically a dead language, as dead as Latin was to the medieval monks in Italy who wrote and spoke it, Erman selected for special investigation those texts which really represented the growth of the language at different periods, and, as he passed from one epoch to another, compared and consolidated his results.

The Newyptische Grammatik (1886) dealt with texts written in the vulgar dialect, the New Kingdom (Dyns. XVII. to XX.), next followed, in the Zeitschrift für ägyptische Sprache and Aller-thumskunde, studies on the Old Kingdom inscription of Una, and the Middle Kingdom contracts of Assiut, as well as on an Old Coptic text of the 3rd century A.D. At a stroke a papyrus of stories written in the popular language of the Middle Kingdom provided Erman with a stepping-stone from Old Egyptian to the Late Egyptian. The Egyptian Grammar and the known form of Egyptian (Zeitschrift für die Deutschen Morgen. Gesellschaft, 1892), and in 1894 he was able to write a little manual of Egyptian for beginners (Ägyptische Grammatik, 2nd ed., 1902), centering on the language of the standard inscriptions of the Middle and New Kingdoms, but accompanying the main sketch with references to earlier and later forms. Of the work of Erman's pupils we may mention Steindorff's little Ägyptische Grammatik (1904), improving greatly on Stern's standard work in regard to phonology and the relationship of Coptic forms to Egyptian, and K. Seeth's Das Ägyptische Verbum (1893). The latter is an extensive monograph on the verb, showing the development of the Ägyptische Grammatik, K. Seeth's Das Ägyptische Verbum (1893). The latter is an extensive monograph on the verb, showing the development of the

Languages and Writing.—The history of the Egyptian language is evidenced by documents extending over a very long range of time. They begin with the primitive inscriptions of the Ist Dynasty (not later than 3500 B.C.) and end with the latest Coptic compositions of about the 14th century A.D. The bulk of the hieroglyphic inscriptions are written in a more or less artificial literary language; but in business documents, letters, popular tales, &c., the scribes often adhered closely to the living form of the tongue, and thus reveal its progressive changes.

The stages of the language are now distinguished as follows:—

Old Egyptian.—This is properly the language of the Old Kingdom. In it we have (a) the recently discovered inscriptions of the Ist Dynasty, too brief and concise to throw much light on the language of that time; and the great collections of spells and ritual texts found inscribed in the Pyramids of the Vth and VIth Dynasties, which must even then have been of high antiquity, though they contain later additions made in the same style; (b) a few historical inscriptions representing the language of the IVth, Vth and VIth Dynasties. The ordinary literary language of the later monuments is modelled on Old Egyptian. It is often much affected

1 Annual reports of the progress of the work are printed in the Zeitschriften der Berlin Academy of Sciences; see also Erman, Zur ägyptischen Sprachforschung, ii. for 1907, p. 400, showing the general trend of the results.
ANCIENT LANGUAGE

by contemporary speech, but preserves in the main the characteristics of the language of the Old Kingdom.

Middle and Late Egyptian.—These represent the vulgar speech of the Middle and New Kingdoms respectively. The former is found chiefly in tales, letters, &c., written in hieratic on papyri of the XVIIIth Dynasty to the end of the Middle Kingdom; also in some inscriptions of the XVIIIth Dynasty. Late Egyptian is seen in hieratic papyri of the XVIIIth to the XXIst Dynasties. The speech of Late Egyptian is very extraordinary, full of late etymologies, obsolete signs, &c., the old orthography being quite unable to adapt itself neatly to the profoundly modified language; nevertheless, this clumsy spelling is expressive, and the very mistakes are instructive as to the pronunciation.

Demic.—Demonic Egyptian seems to represent approximately the vulgar speech of the Saite period, and is written in the "demonic" character, which may be traced back to the XVIIIth Dynasty, if not to a still earlier time. With progressive changes, this form of the language is found in documents reaching down to the fall of Paganism in the 4th century A.D.1 Under the later Ptolemies and the Roman rule documents in Greek are more abundant than in demotic, and the language of the ruling classes have begun to penetrate the masses deeply.

Coptic.—This, in the main, represents the popular language of early Christian Egypt from the 3rd to perhaps the 10th century A.D. when the growth of Coptic as a literary language must have ceased. The Greek alphabet, reinforced by a few signs borrowed from demotic, rendered the spoken tongue so accurately that four distinct, though closely allied, dialects are readily distinguishable in Coptic MSS.; ample remains are found of renderings of the Scriptures into all these dialects. The distinctions between the dialects consist largely in pronunciation, but extend also to the vocabulary, word-formation and syntax. Such interchanges are found as $l$ for r, $s$ for $c$, $k$ for $x$ (dj), final $s$ for final $e$, $a$ for $o$. Early in the 2nd century A.D., pagan Egyptians, or perhaps foreigners settled in Egypt, adopted, as yet unskilfully, to write the native language in Greek letters. This Old Coptic, as it is termed, was still almost entirely free from Greek loan-words, and has not yet been made a modus for each dialect the deliberate speech of grave elders or preachers, and so secured a uniform system of accentuation. The remains of Old Coptic, though very instructive in their marked peculiarities, are as yet too few for definite classification. The main divisions of Christian Coptic as recognized and named at present are: Sahidic (formerly called Theban), spoken in the upper Thebais; Akhmimic, in the neighbourhood of Akhmim, but distinct when the growth of Coptic as a literary language was very early; Fayyumic, full of the Fayyum (formerly named wrongly "Bashmuric," from a province of the Delta); Bohairic, the dialect of the "coast district" (formerly named "Memphite"), spoken in the north-western Delta. Coptic, much alloyed with Arabic, was spoken in Upper Egypt as late as the 15th century, but it has long been a dead language.2 Sahidic and Bohairic are the most important dialects, each of these having left abundant remains; the former spread over the whole of Upper Egypt, and the latter since the 14th century has been the language of the sacred books of Christianity throughout the country, owing to the hierarchical importance of Alexandria and the influence of the ancient monasteries established in the north-western desert.

The above stages of the Egyptian language are not defined with absolute clearness. Progress is seen from dynasty to dynasty or from century to century. New Egyptian abandons almost imperceptibly into demotic, and it may be hoped that gaps which now exist in the development will be filled by further discovery.

Coptic is the only stage of the language in which the spelling gives a clear idea of the pronunciation. It is therefore the mainstay of the scholar in investigating or restoring the word-forms of the ancient language. Greek transcriptions of Egyptian names and words are valuable as evidence for the vocalization of Egyptian. Such are found from the 6th century B.C. in the inscription of Abu Simbel, from the 5th in Herodotus, &c., and abound in Ptolemaic and later documents from the beginning of the 3rd century B.C. onwards. At first sight they may seem inaccurate, but on closer examination the Graecizing is seen to follow definite rules, especially in the Ptolemaic period. A few cuneiform transcriptions, reaching as far back as the XVIIIth Dynasty, to valuable hints as to how Egyptian was pronounced in the 15th century B.C. Coptic itself is of course quite inadequate to enable us to restore Old Egyptian. In it the Old Egyptian verbal forms are mostly replaced by prefixes; though the strong roots are often preserved entire, the weaker consonants and the $s$ have largely or entirely disappeared, so that the language appears as one of biliteral rather than triliteral roots. Coptic is strongly impregnated with Greek words adopted late; moreover, a certain number of Semitic loan-words flowed into Egyptian at all ages, and especially from the 16th century B.C. onwards, displacing earlier words. It is only by the most careful scrutiny, or the exercise of the most piercing insight, that the imperfectly spelled Egyptian has been made to yield up one grammatical secret after another in the light brought to bear upon it from Coptic. Demotic grammar ought soon to be thoroughly comprehensible in its forms, and the study of Late Egyptian should not stand far behind that of demotic. On the other hand, Middle Egyptian, and still more Old Egyptian, which is separated from Middle Egyptian by a wide gap, will perhaps always be to us little more than consonantal skeletons, the flesh and blood of their vocalization being for the most part irretrievably lost.

In common with the Semitic languages, the Berber languages of North Africa, and the Cushite languages of North-East Africa, Egyptian of all periods possesses grammatical gender, expressing the masculine and feminine; similarly few languages have this peculiarity; and our own great Indo-European group, which possesses it, is distinguished from those above mentioned by having the neuter gender in addition. The characteristic triliteral roots of all the Semitic languages seemed to separate them widely from others; but certain traits have caused the Egyptian, Berber and Cushite groups to be classed together as the subfamilies of a Hamitic group, remotely related to the Semitic. The biliteral number of Coptic is of the same type as that which was believed to exist in Egyptian, led philologists to suspect that Egyptian might be a surviving witness to that far-off stage of the Semitic languages when triliteral roots had not yet been formed from presumed original bilaterals; Seth's investigations, however, prove that the Coptic bilaterals are themselves derived from Old Egyptian triliterals, and that the triliteral roots enormously preponderated in Egyptian of the earliest known form; that view is, therefore, no longer tenable. Many remarkable phonetic changes have occurred in Egyptian, through the influence of hieroglyphic spelling, a more precise transcription of the consonants in the latter being sometimes added.

1 In the temple of Philae, where the worship of Isis was permitted to continue till the reign of Justinian, Brugsch found demotic inscriptions with dates to the end of the 5th century.

2 The Arabic dialects, which gradually displaced Coptic as Mahommedanism supplanted Christianity, adopted but few words of the old native stock.

3 In the articles referring to matters of Egyptology in this edition, Graecized forms of Old Egyptian names, where they exist, are commonly employed; in other cases names are rendered by their actual equivalents in Coptic or by analogous forms. Failing all such means, recourse is had to the usual conventional groups having of hieroglyphic spelling, a more precise transcription of the consonants in the latter being sometimes added.
resemblances have been observed in the grammatical structure between Berber and Cushite groups with Semitic (cf. H. Zimmer, Vergleichende Grammatik d. semitischen Sprachen, Berlin, 1898, especially pronouns and verbs); but the relationship must be very distant, and there are no ancient documents that can take back the history of any one of those languages more than a few centuries. Their connexion with Semitic and Egyptian, therefore, remains at present an obscure though probable hypothesis. On the other hand, Egyptian is certainly related to Semitic. Even before the triliteralism of Old Egyptian was recognized, Erman showed that the so-called pseudo-participles had been really in meaning and in form a precise analogue of the Semitic perfect, though its original employment was almost obsolete in the time of the earliest known texts. Triliteralism is considered the most essential and most peculiar feature of Semitic. But there are, besides, many other resemblances in structure between the Semitic languages and Egyptian, so that, although the two vocabularies present few points of clear contact, there is reason to believe that Egyptian was originally a characteristic member of the Semitic family of languages. See Erman, "Das Verhältnis d. ägyptischen zu d. semitischen Sprachen" (Zeitschrift d. deutschen morgenl. Gesellschaft, 1892); Zimmern, Vergl. Gram., 1898; Erman, "Flexion d. ägyptischen Verbums" (Sitzungsberichte d. Berl. Akad., 1900). The Egyptians proper are not, and so far as we can tell were never, Semitic in physical features. As a possible explanation of the facts, Erman suggests that a horde of conquering Semites, like the Arabs of a later day, imposed their language on the country, but disappeared, being weakened by the climate or absorbed by the native population. The latter acquired the Semitic language imperfectly from their conquerors; they expressed the verbal conjugations by periphrases, mispronounced the consonants, and so changed greatly the appearance of the vocabulary, which also would certainly contain a large proportion of native non-Semitic roots. Strong consonants gave place to weak consonants (as h s has done to j), in the modern Arabic of Egypt, and then the weak consonants disappearing altogether produced bilateral from the triliterals. Much of this must have taken place, according to the theory, in the prehistoric period, but the loss of weak consonants, of y, and of one of two repeated consonants, and the development of periphrastic conjugations continued to the end. The typical Coptic root thus became bilateral rather than trilateral, and the verb, by means of periphrases, developed tenses of remarkable precision. Such verbal resemblances as exist between Coptic and Semitic are largely due to late exchanges with Semitic neighbours.

The following sketch of the Egyptian language, mainly in its earliest form, which dates from some three or four thousand years B.C., is founded upon Erman's works. It will serve to contrast with Coptic grammar on the one hand and Semitic grammar on the other.

**ROOTS**

Egyptian roots consist of consonants and semi-consonants only, the inflection being effected by internal vowel-change and the addition of consonants or vowels at the beginning or end. The Egyptian system of writing, as opposed to the Coptic, showed only the consonantal skeletons of words: it could not record internal vowel-changes; and semi-consonants, even when radicals, were often omitted in writing.

**PERSONAL PRONOUNS**

Singular
1. c. lw (?) later st. 2. m. kw. 3. m. ifn., surviving only in late st. 3. c. fny.
2. c. lmn. 2. c. lny.

Plural
1. c. m. 2. c. lmn.

**VERBAL FORMS**

Singular:
1. m. ifn. 2. m. ifn.

Plural:
1. m. ifn. 2. m. ifn. 3. m. ifn.

**SUFFIXES**

1. ify. 2. ify.

From these are derived the suffixes, which are shortened forms attached to nouns to express the possessor, and to verbs to express the subject. In the latter case the verb was probably in the participle, so that lfgwn-lwn, "they hear," is literally "hearing are they." The singular suffixes are: (1) c.-l.; (2) m.-f., l.-l.; (3) m.-f., l.-l.;—the dual and plural have no special forms.

Another series of absolutes is: (2) m. ifn, 2. m. ifn, fnm, ifn, fnm, 3. m. fnm, fnm. Of these ifn, fnm, &c., are emphatic forms.

Many of the above absolute pronouns were almost obsolete even in the Old Kingdom. In ordinary texts some survive, especially in lists of verbs, namely, ut, bs, ln, m, st. The suffixes of all numbers and persons except the dual were in full use throughout, to Coptic; sn, however, giving way to a new suffix, -sr, which developed first in the New Kingdom.

Another absolute pronoun of the first person is lnk, ANOK, like Heb. waw. It is associated with a series for the second and third persons: ni-ik, ni-ik, ni-ik, ni-ik, &c.; but from their history, use and form, it seems probable that the last are of later formation, and are not to be connected with the Semitic pronouns (chiefly of the 2nd person) resembling them.

**DEMONSTRATIVE PRONOUNS**

There are several series based on m. p.; l. t.; pl. n; but n as a plural seems later than the other two. From them are developed a weak demonstrative to which possessive suffixes can be attached, producing the definite and possessive articles (p., n., m. "the," prvs., "his," pry-s "her," &c.) of Middle Egyptian and the later language.

**NOUNS**

Two genders, m. (ending w, or nothing), f. (ending l). Three numbers: singular, dual (m. wfl, f. l. gladi), gradually became obsolete, plural (m. wfl, f. l. gl). No case-endings are recognizable, but construct forms—to judge by Coptic—were in use. Masculine and feminine nouns of instrument or material are formed from verbal roots by prefixing, e.g. m. ms-dm-l, "stirrumb," from msdm, "paint the eye." Substantives and adjectives are formed from substantives and prepositions by the addition of y in the masculine; e.g. n-ly, "city," ny-y, "belonging to a city," lly, "citizen"; yr, "upon," yr-wr, "of," pl. yr-wr, "upper." This is not unlike the Semitic nishe ending ty, ay (e.g. Ar. beld, "city," beled, "belonging to a city"). Adjectives follow the nouns they qualify.
The imperative shows no ending in the singular; in the plural it has \( y \), and later \( w \); cf. Semitic imperative.

The infinitive is of special importance on account of its being represented very fully in Coptic. It is generally the same as the Semitic infinitive, but feminine in III. inf. (as in Semitic), and in causatives of biliterals.

There are relative forms of \( s i m - f \) and \( s i m - n - f \), respectively \( s i m - n - w \), \( s i m - n - f \), \( s i m - n - f - f \), etc. They are used when the relative is the subject of the relative sentence, or stands alone, in the same sense as \( s i m - f \). There are also relative forms of \( s i m - f \) and \( s i m - n - f \), respectively \( s i m - n - w \), \( s i m - n - f \), \( s i m - n - f - f \), etc. They are used when the relative is the object of the relative sentence, or stands alone.

There are close analogies between the functions of masculine forms in Egyptian and Semitic; and the Berber languages possess a relative form of the verb.

Participles.—These are active and passive, perfect and imperfect, in the old language, but all are replaced by periphrases in Coptic.

Verbal Adjectives.—There is a peculiar formation, \( s i m - t - y - f \), \( s i m - t - y - f - y \), “he who shall hear,” probably meaning originally “ he is a hearer,” from a noun which was used figuratively in connection with a subject. Thus \( s i m - t - y - f \) may mean “ he whom he hears,” “ the whole he hears,” “ the whole he is praised,” “ he to whom he hears [someone] speaking,” “ he who is heard.”

There are close analogies between the functions of masculine forms in Egyptian and Semitic; and the Berber languages possess a relative form of the verb.

Participles.—These are active and passive, perfect and imperfect, in the old language, but all are replaced by periphrases in Coptic.

Verbal Adjectives.—There is a peculiar formation, \( s i m - t - y - f \), \( s i m - t - y - f - y \), “he who shall hear,” probably meaning originally “ he is a hearer,” from a noun which was used figuratively in connection with a subject. Thus \( s i m - t - y - f \) may mean “ he whom he hears,” “ the whole he hears,” “ the whole he is praised,” “ he to whom he hears [someone] speaking,” “ he who is heard.”

to make it nearly certain that the values of all were obtained on the same principles. Some of the ancient words from which the phonetic values were derived probably fell very early into disuse, and may never be discoverable in the texts that have come down to us. The following are among those most easily explained:

\[
\text{reed} \text{ flower, value } y \text{ and } \mathbf{m}; \text{ from } \mathbf{P}, \mathbf{y}, \mathbf{m}, \text{ "reed".}
\]

(it seems as if the two values \( y \) and \( \mathbf{m} \) were obtained by choosing first one and then the other of the semi-consonants composing the name. They are much confused, and a conventional symbol \( \mathbf{1} \) has to be adopted for rendering \( y \).

\[
\text{forearm, value } (p); \text{ from } \mathbf{\mathfrak{P}}, \text{ "hand".}
\]

\[
\text{mouth, value } r; \text{ from } \mathfrak{r}, \text{ "mouth".}
\]

\[
\text{belly and teats, value } \mathbf{z}; \text{ from } \mathfrak{t}, \mathbf{1}, \text{ "belly".}
\]

(The feminine ending is here, as usual, neglected.)

\[
\text{tank, value } f; \text{ from } \mathfrak{f}, \text{ "tank".}
\]

\[
\text{slope of earth, value } g; \text{ or brickwork, } \mathfrak{d}, \text{ "slope".}
\]

(The doubled weak consonant is here neglected.)

\[
\text{hand, value } d; \text{ from } \mathfrak{d}, \text{ "hand".}
\]

\[
\text{cobra, value } s; \text{ from } \mathfrak{s}, \text{ "cobra".}
\]

For some alphabetic signs more than one likely origin might be found, while for others, again, no clear evidence of origin is yet forthcoming.

It has already been explained that the writing expresses only consonants. In the Graeco-Roman period various imperfect attempts were made to render the vowels in foreign names and words by the semi-vowels as also by the consonant \( y \) which \( \mathfrak{y} \) originally represented having been reduced in speech to the power of \( s \) only. Thus, \( \text{Pharaohs, Antonious, } \mathfrak{N}, \text{ etc.} \)

Much earlier, throughout the New Kingdom, a special "syllabic" orthography, in which the alphabetic signs for the consonants are generally replaced by groups or single signs having the value of a consonant followed by a semi-vowel, was used for foreign names and words, e.g.

\[
\text{harp, was written } \mathfrak{z}, \text{ "harp".}
\]

\[
\text{Hamath, was written } \mathfrak{n}, \text{ "Hamath".}
\]

According to W. Max Müller (Aisien und Europt, 1893, chap. v.), this represents an endeavour to express the vocalization; but, if so, it was carried out with very little system. In practice, the semi-vowels are generally negligible. This method of writing can be traced back into the Middle Kingdom, if not beyond, and it greatly affected the spelling of native words in New Egyptian and demotic.

Determinatives.—Most signs can on occasion be used as determinatives, but those that are very commonly employed as phonograms or as secondary word-signs are seldom employed as determinatives; and when they are so used they are often somewhat differentiated. Certain generic determinatives are very common, e.g.

\[
\text{of motion.}
\]

\[
\text{of acts involving force.}
\]

\[
\text{of divinity.}
\]

\[
\text{It seems that "acrophony" (giving to a sign the value of the first letter of its name) was indulged in only by priests of the latest age, inventing fantastic modes of writing their "vain repetitions" on the temple walls.}
\]
PALAEOGRAPHY

EGYPT

(6) by (i). Biliteral phonograms are very rare as phonetic complements, nor are two biliteral phonograms employed together in writing the radicals of a word.

Spelling of words purely in phonetic or even alphabetic characters is not uncommon, the determinative being generally added. Thus in the pyramidal texts we find br, "become," written in one copy of a text, in another . Such variant spellings are very important for fixing the readings of word-signs. It is noteworthy that though words were so freely spelled in alphabetic characters, especially in the time of the Old Kingdom, no advance was ever made towards excluding the cumbersome word-signs and biliteral phonograms, which, by a judicious use of determinatives, might well have been rendered quite superfluous.

Abbreviations.—We find l, strictly "nq” s standing for the ceremonial vinal nq ws, snb. "Life, Prosperity and Health," and in course of time was used in accounts instead of dm, ‘total.’

Monograms are frequent and are found from the earliest times. Thus m, mentioned above are monograms, the association of and having no pictorial meaning. Another common monogram is , i.e. and for "Hathor.

A word-sign may be compounded with its phonetic complement, as "white," or with its determinative, as "silver."

The table on the opposite page shows the uses of a few of the commoner signs.

The phonic value of hieroglyphic was fully appreciated in Egypt. The aim of the artist-scribe was to arrange his variously shaped characters into square groups, and this could be done in great measure by taking advantage of the different ways in which many words could be spelt. Thus could be written , by , , but some words in the classical writing were intractable from this point of view. It is obvious that the alphabetic signs played a very important part in the formation of the groups, and many words could only be written in alphabetic signs. A great advance was therefore made when several homophones were introduced into the alphabet in the Middle and New Kingdoms, partly as the result of the wearing away of old phonetic distinctions, giving the choice between and , and , , . But in later times the number of homophones in use increased greatly throughout the different classes, the tendency being much helped by the habit of fanciful writing, but few of these homophones found their way into the cursive script. Occasionally a scribe of the old times indulged his fancy in "sportive" or "mysterious" writing, either inventing new signs or employing old ones in unusual meanings. Short sporting inscriptions are found in tombs of the XIth Dynasty; some groups are so written] cursively in early medical papyri, and certain religious inscriptions in the royal tombs of the XIXth and XXth Dynasties are in secret writing. Fanciful writing abounds on the temples of the Ptolemaic and Roman periods.

PALAEOGRAPHY

Hieroglyphic.—The main division is into monumental or epigraphic hieroglyphs and written hieroglyphs. The former may be rendered by the sculptor or the painter in stone, on wood, &c., with great delicacy of detail, or may be simply sunk or painted in outline. Written hieroglyphs are depicted in running script, and the student is of great value to the student investigating the origins of their values. No other system of writing bears upon its face so clearly the history of its development as the Egyptian; yet even in this a vast amount of work is still required to detect and disentangle the details. Monumental hieroglyphic did not cease till the 3rd century A.D. (Temple of Ema). The written hieroglyphs, formed by the scribe with the reed pen on papyrus, leaves, wooden tablets, &c., have their outlines more or less abbreviated, producing eventually the cursive scripts hieratic and demotic. The written hieroglyphs were employed at all periods, especially for official texts.

Hieratic.—A kind of cursive hieroglyphic or hieratic writing is found even in the Ist Dynasty. In the Middle Kingdom it is well

Rosetta stone. One of the most characteristic distinctions of later demotic is the minuteness of the writing. Hieroglyphic is normally written from right to left, the signs facing to the commencement of the line; hieratic is written from left to right, the same direction. But monumental hieroglyphic may also be written from left to right, and is constantly so arranged for purposes of symmetry, e.g., the inscriptions on the two jambs of a door are frequently turned in opposite directions; the same is frequently done with the short inscriptions seen on ostraca, among the figures, in order to distinguish one label from another. In modern founts of type, the hieroglyphic signs are made to run from left to right, in order to facilitate the setting where European text is mixed with the Egyptian. The table on next page shows them in their more correct position, in order to display more clearly their relation to the hieratic and demotic equivalents. Clement of Alexandria states that in the Egyptian schools the pupils were first taught the "epigraphic" style of writing (i.e., hieratic), secondly the "hieratic" employed by the sacred scribes, and finally the "hieroglyphic" (Stoews. v. 657). It is not clear whether they classified the signs of the huge hieroglyphic syllabary with any strictness. The only native work on the writing that has come to light as yet is a fragmentary papyrus of Roman date which has a table in parallel columns of hieroglyphic signs, with their hieratic equivalents and words written in hieratic describing them or giving their values or meanings. The list appears to have comprised about 450 signs, including most of those that occur commonly in hieratic. They are to some extent classified. The bee \( \text{Apis} \) heads the list as a royal sign, and is followed by figures of nobles and other human figures in various attitudes, more or less grouped among themselves. Animals, reptiles and fishes, scorpion, animals again, twenty-four alphabetic characters, parts of the human body carefully arranged from \( \text{O} \) to \( \text{A} \), thirty-two in number, parts of animals, celestial signs, terrestrial signs, vases. The arrangement down to this point is far from strict, and beyond it is almost impossible to describe concisely, though there is still a rough grouping of characters according to resemblance of form, nature or meaning. It is a curious fact that not a single bird is visible on the fragments, and the trees and plants, which might easily have been collected in a compact and well-defined section, are widely scattered. Why the alphabetic characters are introduced where they are is a puzzle; the order of these is: --- \( \text{Apis} \) \( \text{O} \) \( \text{A} \) \( \text{J} \) \( \text{H} \) \( \text{K} \) \( \text{L} \) \( \text{M} \) \( \text{N} \) \( \text{P} \) \( \text{Q} \) \( \text{R} \) \( \text{S} \) \( \text{T} \) \( \text{U} \) \( \text{V} \) \( \text{W} \) \( \text{X} \) \( \text{Y} \) \( \text{Z} \) \( \text{I} \) \( \text{E} \) \( \text{G} \) \( \text{F} \) \( \text{D} \) \( \text{C} \) \( \text{B} \) \( \text{A} \). Three others, \( \text{S} \) \( \text{S} \) \( \text{S} \) and \( \text{S} \) \( \text{S} \) \( \text{S} \), had already occurred amongst the fish and reptiles. There seems to be no logical aim in this arrangement of the alphabetic characters and the series is incomplete. Very probably the Egyptians never constructed a really systematic list of hieroglyphs. In modern lists the signs are classified according to the nature of the objects they depict, as human figures, plants, vessels, instruments, &c. The “Hieroglyphics” may be used as a native name, but its author, if really an Egyptian, had no knowledge of good writing. His production consists of two elaborate complementary lists: the one describing sign-pictures and giving their meanings, the other cataloguing ideas in order to show how they could be expressed in hieroglyphic. Each seems to us to be made up of curious but perverted reminiscences elicited out of invention; but they might prove to represent more truly the usages of mystics and magicians in designing amulets, &c., at a time approaching the middle ages.

as used by carpenters. There are no dated specimens till the Assyrian iron saws (48) of the 7th century B.C. Drills were of flint (49) for hard material and bead-making, of bronze for wood-work. In the Assyrian tools iron drills are of slightly twisted second flint (50), and of the bit-band type with two scraping edges (51). In Roman times the modern V drill (52) is usual. The drill was worked by a stock with a loose cap (53), rotated by a drill bow, in the XIIIth to Roman Dynasties. The pump drill with cords twisted round it was in Roman use. The bow drill (56) was used as a fire drill to rotate wood (55) on wood (57); and the cap (54) for such use was of hard stone with a highly polished hollow. The drill brace appears to have been used by Assyrians in the 7th century B.C. Pliers of bronze tapering (58), to enlarge holes in leather, etc., were common in all ages.

Fighting Weapons.—The battle-axe has been described above with axes. The flint dagger (50) is found from S.D. 40-56. A very finely made copper dagger (60) with deep midrib is dated to between 55 and 60 S.D. Copper daggers with parallel ribbing (61) down the middle are common in the XIIth-XIVth Dynasties; and in the XVIIIth-XXth Dynasties they are often shown in scenes and on figures. The falchion with a curved blade (62) belongs to the XVIIIth-XXth Dynasty. The rapier (63) or lengthened dagger is rarely found, and is probably of prehistoric Greek origin. The sword is of Greek and Roman age, always double-edged and of iron. The spear is not commonly found in Egypt, until the Greek age, but it is represented from the XIIth Dynasty onward; it belonged to the Semitic people (L.D. ii. 133). The bow was always of wood, in one piece in the prehistoric and early times, also of two horns in the Ist Dynasty; but the compound bow of horn is rarely found, only as an importation, in the XVIIIth Dynasty. The arrow-heads of flint (64-66) and of bone (68-69) were pointed, and also square-ended (67) for hunting (P.R.T. ii. viii.; vii. A. 7.; xxxiv.). The copper arrow-heads appear in the Xth Dynasty, of blade form with tang (70); the triangular form (72), and leaf form with socket (71), are of the XXVth Dynasty. Triangular iron arrows with tang are of the same age. Spears show that the shaft was a reed, sockets show that it was of wood. Many early arrows (XIIth) have only hard wood points of conical form. The sling is rarely shown in the XIXth-XXth Dynasties; and the only known example is probably of the XXVth.

Hunting Weapons.—The forked lance of flint was at first wide with slight hollow (73) from S.D. 32-43; then the hollow became a V notch (74) in 38 S.D. and onward. The lance was fixed in a wooden shaft for throwing, and held in by a check-cord from flying too far if it missed the animal (P.N. LXXIII.). The forked bow (first of bone) became common in copper (76, 77) from S.D. 36 onward. The boomerang or throw-stick (78) was used from the ISt to the XXIIInd Dynasty, and probably later. Fish-hooks of copper (79-83) are found from the 1st Dynasty to Roman times. A trap for animals' legs, formed by splints of palm stick radiating round a central hole, is figured in S.D. 60, and one was found of probably the XXth Dynasty. Fishing nets were common in all historic times, and the lead sinkers (83) and stone sinkers (84) are often found under the XVIIIth-XXth Dynasties.

Agricultural Tools.—The hoe of wood (85) is the main tool from the late prehistoric time, and many have been found of the XVIIIth Dynasty. With the handle lengthened (86) and turned forward, this became the plough (87) is the hicloth, 88 the drawing of a plough; this was always sloping, and never the upright post of the Italian type. The rake of wood (89) is usual in the XIIth and XVIIIth Dynasties. The fork (90), used for tossing straw, was common in the Old Kingdom, but none has been found. The sickle was of wood (92), with flints (91) inserted, apparently a copy of the ox-jaw and teeth. The notched flints for it are common from the 1st to the XVIIIth Dynasty. In Roman times the same principle was followed, by making an iron sickle with a deep groove, in which was inserted the cutting blade of steel (P.E. XXIX.). Shovel-boards, to hold in right (93) or left hand for scraping up the grain in winnowing, are usual in the XVIIIth Dynasty, and are figured in use in the Old Kingdom.

Pruning knives with curved blades (94) are Italic, and were made of iron by the Romans. Corn grinders were flat oval stones, with a smaller one lying cross-ways (95), and slid from end to end. Such were used from the Old Kingdom down to late times. In the Roman period a larger stone was used, with a rectangular piece (90) sliding on it, in Roman times it was made larger, and let it slip out below for grinding. The quern with rotary motion is late Roman, and still used by Arabs. The large circular millstones of Roman age worked by horse-power are usually made from slices of granite columns.

Building Tools.—The adze described above was used for dressing blocks of limestone. The brick-mould was an open frame, with one side prolonged into a handle (97), exactly as the modern mould. The plasterers' floats (98) were entirely cut out of wood. The mud rake for mixing mortar is rather narrower than the modern form. The square (99) and plummet (100, 101) have remained unchanged since the XIXth Dynasty. For dressing flat surfaces three wooden pegs (102) of equal length were used; a string was stretched between the tops of two, and the third peg was set on the point to be tested and tried against the string.

Thread-Work.—Stone spindle whorls (103) are common in the prehistoric age; wooden ones were usual, of a cylindrical form (104) in the XIth, and conical (105) in the XVIIIth Dynasty. The thread was secured by a spiral notch in the stick. In Roman times an iron hook on the top held the thread (106) as in modern spindles. Needles of copper were made in the prehistoric, as early as S.D. 48, and very delicate ones by S.D. 71. Gold needles are found of the Ist Dynasty. Fine ones of bronze are common in the XVIIIth Dynasty, and some with two eyes at right angles, one above the other, to carry two different threads. The copper boddin is found in S.D. 70. Netters are common, of rib bones, pointed (107); the thread was wound round them. Long netting needles were probably brought in by the dynastic people as they figure in the hieroglyphs. Finely-made ones are found in the XVIIIth Dynasty and later. Reels were also commonly used for net making, of pottery (108) or even pebbles (109) with a groove chopped around. The flint vase-grinders were used in the early dynasties (110), and also sandstone grinders for hollowing larger vases (111).

Stone-Work.—In the prehistoric ages stone building was unknown, but many varieties of stones were used for carving into vases, amulets and ornaments. The stone vases were at first of cylindrical forms, with a foot, and ears for hanging. These are worked in brown basalt, syenite, porphyry, alabaster and limestone. In the second prehistoric civilization barrell-shaped vases became usual, and to the former materials were added slate, grey limestone and breccia. Serpentine appears later, and diorite towards the close of the prehistoric ages. Flat dishes were used in earlier times; gradually deeper forms appear, and lastly the deep bowl with turned-in edge belongs to the close of the prehistoric time and continued common in the earlier dynasties (P.D.F. 19). This stone-work was usually formed on the outside with rotary motion, but sometimes the vase was rotated upon the grinder (Q. H. 17). The interior was ground out by cutters (figs. 100, 111) fixed in the end of a stick and revolved with a weight on the top, as shown in scenes on the tombs of the Vth Dynasty. The cutters were sometimes flints of a crescent shape (P. Ab. ii. lili. 24), but more usually grinders blocks of quartzite sandstone (26-34), and occasionally of diorite (Q. H. xxi. 19., ii.). These blocks were fed with sand and water to give the bite on the stone (P. Ab. i. 26). The outside of the vases were entirely wrought by handwork, with the polishing lines crossing diagonally. Probably the first forming was done by chopping and hammer-dressing, as in later times; the final facing of the hard stones was doubtless by means of emery in block or powder, as emery grinding blocks are found.

In the early dynasties the hard stones were still worked, and the 1st dynasty was the most splendid age for vases, bowls, and dishes of the finest stones. The royal tombs have preserved an enormous quantity of fragments, from which five hundred
varied forms have been drawn (P.R.T. ii. xlii.-liii. 6). The materials are quartz crystal, basalt, porphyry, syenite, granite, volcanic ash, various metamorphics, serpentine, slate, dolomite marble, alabaster, many coloured marbles, sarrachine marble, grey and white limestone is not known at the present. The most splendid vase is one from Nebhepet (Hephesteropolis), of syenite, 2 ft. across and 16 in. high, hollowed so as to be marvellously light and highly polished (Q. H. xxxvii). Another branch of stone-work, surface carving, was early developed by the artistic dynastic race. The great palettes of slate covered with elaborate reliefs are probably all of the pre-Menite kings; the most advanced of them having the figure of Narmer, who preceded Menes. Other carving full of detail is on the great mace-heads of Narmer and the Scorpion king, where scenes of ceremonies are minutely engraved in relief. In the Ist Dynasty the large tombstones of the kings are of bold work, but the smaller stones of private graves vary much in the style, many being very coarse. All of this work was by hammer-dressing and scraping. The scrapers seem to have always been of copper.

The earliest use of stone in buildings is in the tomb of King Den (Ist Dynasty), where some large flat blocks of red granite seem to have been part of the decoration. The most famous chamber known is that of Kha-aahkhemenu (end of the IIId Dynasty). This is of blocks of limestone whose faces follow the natural cleavages, and only dressed where needed; part is hammer-dressed, but most of the surfaces are adze-dressed. The adze was of stone, probably flint, and had a short handle (P.R.T. ii. 13). The same kind also wrought granite with inscriptions in relief. In the close of the IIIId Dynasty a great impetus was given to stone-work, and the grandest period of refined masonry is at the beginning of the IVth Dynasty under Cheops. The tombs of Ménemumut and Snefru are built with immense blocks of limestone of 20 and 33 tons weight. The dressing of the face between the hieroglyphs was done partly with copper and partly with flint scrapers (P.M. 27). The most splendid masonry is that of the Great Pyramid of Cheops. The blocks of granite for the roofing are 56 in number, of an average weight of 54 tons each. These were cut from the water-worn rocks at the Catacar—the soundest source for large masses, as any incipient flaws are well exposed by wear. The blocks were quarried by cleavage; a groove was run along the line intended, and about 2 ft. apart holes about 4 in. wide were jumped downward from it in the intended plane; this prevented a skew fracture (P.T. 93). In shallower masses a groove was run, and then holes, apparently for wedges, were sunk deeper in the course of it; whether wetted wood was used for the force is not known, but it is probable, as no signs are visible of crushing the granite by hard wedges. The facing of the cloven surfaces was done by hammer-dressing, using rounded masses of quartzose hornstone, held in the hand without any handle. In order to get a hold for moving the blocks without bruising the edges, projecting lumps or bosses were left on the faces, about 6 or 8 in. across and 1 or 2 in. thick. After the block was in place the boss was struck off and the surface dressed and polished (P.T. 78, 83). In the pyramid of Cheops the blocks were all faced before building; but the later granite temple of Chephren and the pyramid of Mycerinus (Menkaura, Menkere) show a system of building with an excess of a few inches left rough on the outer surface, which was dressed away when in position (P.T. 110, 132).

The flatness of faces of stone or rock (both granite and limestone) was tested by placing a true-plane trial plate, smeared with red ochre, against the dressed surface, as in modern engineering. The door-case being thus rendered ready, were the edges of it had to be further dressed away; and this process was continued until the ochre touched points not more than an inch apart all over the joint faces, many square feet in area. On stones too large for facing-plates a diagonal draft was run, so as to avoid any wind in the plane (P.T. 83).

The cutting of granite was not only by cleavage and hammer dressing, but also by cutting with harder materials than quartz such as emery. Long saws of copper were fed with emery powder, and used to saw out blocks as much as 7½ ft. long (P.T. Plate XIV.). In other cases the very deep scores in the sides of the saw-cut suggest that fixed cutting points were inserted in the copper saws; and this would be parallel to the saw-cuts in the very hard limestone of the Palace of Tiryns, in which a piece of masonry was seen to have been cut with a copper saw. The saw has a broad slot, large chips of emery, too long and coarse to serve as a powder, but suited for fixed teeth. A similar method was common for circular holes, which were cut by a tube, either with powder or fixed teeth. These tubular drills were used from the IVth Dynasty down to late times, in all materials from alabaster up to human. The resulting cores are more regular than those of modern rock-drilling.

Limestones in the Great Pyramid, as elsewhere, was dressed by chopping it with an adze, a tool used from prehistoric to Roman times for all soft stones and wood. This method was carried on up to the point of getting contact with the facing-plate at every inch of the surface; the cuts cross in various directions. For removing rock in reducing a surface to a level, or in quarrying, cuts were made with a pick, forming straight trenches, and the blocks were then broken out between these. Finally, by tying a rope round the level 4...

Ancient Egyptian Tools.
lie in the plane thus defined by two traces at the ends (P.M. VIII.).

Metal-Work.— Copper was wrought into pins, a couple of inches long, with loop heads, as early as the oldest prehistoric graves, before the use of weaving, and while pottery was scarcely developed. The use of harpoons and small chisels of copper next arose, then broad flaying knives, needles and adzes, lastly the axe was the tool most common. On these prehistoric tools, when in fine condition, the original highly-polished surface remains. It shows no trace of grinding lines or attrition, nor yet of the blows of a hammer. Probably it was thus highly finished by beating between polished stone hammers which were almost flat on the face. Most likely the forms of the tools were cast to begin with, and then finished and polished by fine hammering. A series of moulds for casting in the Xth Dynasty show that the forms were carved out in thick pieces of pottery, and then lined with fine ashly clay. The mould was single, so that one side of the tool was the open face of metal. As early as the pyramid times solid casting by cire perdue was already used for figures: but the copper statues of Pepi and his son seem, by their thinness and the piecing together of the parts, to have been entirely hammered out. The portraiture in such hammer work is amazingly life-like. By the time of the XIIth Dynasty, and perhaps earlier, cire perdue casting over an ash core became usual. This was carried out most skilfully, the metal being often not \( \frac{1}{32} \) in. thick, and the core truly centred in the mould. Casting bronze over iron rods was also done, to gain more stiffness for thin parts.

In gold work the earliest jewelry, that of King Zer of the Ist Dynasty, shows a perfect mastery of working hollow balls with minute threading holes, and of soldering with no trace of excess nor difference of colour. Thin wire was hammered out, but there is no ancient instance of drawn wire. Castings were not trimmed by filing or grinding, but by small chisels and hammering (P.R.T. ii. 17). In the XIIth Dynasty the soldering of the thin cells for the cloisonne inlaid pectorals, on to the base plate, is a marvellous piece of delicacy; every cell has to be perfectly true in form, and yet all soldered, apparently simultaneously, as the heat could not be applied to successive portions (M.D. i. 1.). Such work was kept up in the XVIIIth and XXXVth Dynasties. There is nothing distinctive in later jewelry different from Greek and Roman work elsewhere.

Glaze and Glass.— From almost the beginning of the prehistoric age there are glazed pottery beads found in the graves: and glazing on amulets of quartz or other stones begins in the middle of the prehistoric. Apparently then glazing went together with the working of the copper ores, and probably accidental slags in the smelting gave the first idea of using glass intentionally. The development of glazing at the beginning of the dynasties was sudden and effective. Large tiles, a foot in length, were glazed completely all over, and used to line the walls of rooms; they were retained in place by deep dovetails and ties of copper wire. Figures of glazed ware became abundant: a kind of visiting card was made with the figure of a man and his titles to present in temples which he visited; and glazed ornaments and toggles for fastening dresses were common (P. Ab. ii.). Further, besides his funerary glaze on a large scale, differently coloured glasses were used, and even fused together. A piece of a large tile, and part of a glazed vase, have the royal titles and name of Menes, originally in violet inlay in green glaze. There was no further advance in the art until the great variety of colours came into use about 4000 years later. In the Xth Dynasty a very thin smooth glaze was used, which became rather thicker in the XVIIIth. The most brilliant age of glasses was under Amenophis III. His tomb at Thebes was the most famous in ancient Egypt. Various colours were used; beside the old green and blue, there were purple, violet, red, yellow and white. And a profusion of forms is shown by the moulds and actual examples, for necklaces, decorations, inlay in stone and applied reliefs on vases. Under Set II. cartouches of the king in violet and white glaze are common; and under Ramses III. there were vases with relief figures, with painted figures, and tiles with coloured reliefs of captives of many races. The latter development of glazing was in thin delicate apple-green ware with low relief designs, which seem to have originated under Greek influence at Naucratis. The Roman glaze is thick and coarse, but usually of a brilliant Prussian blue, with dark purple and apple-green; and high reliefs of wreaths, and sometimes figures, are common.

Though glaze begins so early, the use of the glassy matter by itself and not as a filler, does not occur till the late XVIIIth Dynasty. The first glass was black and white under Tethmosis (Tahutmes) III. It was not fused at a high point, but kept in a pasty state when working. The main use of it was for small vases; these were formed upon a core of sandy paste, which was modelled on a copper rod, the rod being the core for the neck. Round this core threads of glass were wound of various colours; the whole could be reset in the furnace to soften it for moulding the foot or neck, or attaching handles, or dragging the surface into various patterns. The colours under later kings were as varied as those of the glazes. Glass was also wheel-cut in patterns and shapes under Akhenaton. In later times the main work was in mosaics of extreme delicacy. Glass rods were pilled together to form a pattern in cross-section. The whole was then heated until it perfectly adhered, and the mass was drawn out lengthways so as to render the design far more minute, and to increase the total length for cutting up. The rods were then placed across, and the use of coloured glass was for cutting in the shapes of hieroglyphs for inlaying in wooden coffins to form inscriptions. Glass amulets were also commonly placed upon Ptolemaic mummies. Blown glass vessels are not known until late Greek and Roman times, when they were of much the same manufacture as glass elsewhere. The supposed figures of glass-blowers in early scenes are really those of smiths, blowing their fires by means of reeds tipped with clay. The vases for inlaying were made in Italy were greatly used in Egypt in Roman times, and are like those found elsewhere. A distinctively late Egyptian use of glass was for weights and vase-stamps, to receive an impress stating the amount of the weight or measure. The vase-stamps often state the name of the contents (always seeds or fruits), probably not to show what was in them, but to show for what kind of seed the vessel was a true measure. These measure stamps bear names dating them from A.D. 650 to about 950. The large weights of ounces and pounds are disks or cuboid blocks; they are dated from 720 to 785 for the lesser, and to A.D. 915 for larger weights. The greater number are, however, small weights for testing gold and silver coins of later caliphs from A.D. 952 to 1171. The system was not, however, Arab, as there are a few Roman vaser stamps and weights. Of other medieval glass may be noted the splendid glass vases for lamps, with Arab inscriptions fused in the neck. No enamelling was ever done by Egyptians, and the few rare examples are all of Roman age due to foreign work.

The manufacture of glass is shown by examples in the XVIIIth Dynasty. The blue or green colour was made by fritting together silica, lime, alkaline carbonate and copper carbonate; the latter varied from 3% in delicate blues to 30% in deep purple blues. The silica was needed quite pure from iron, in order to get the rich blues, and was obtained from calcined quartz pebbles; ordinary sand will only make a green frit. These materials were heated in pans in the furnace so as to combine in a pasty, half-fused condition. The coloured frit thus formed was used as paint in a wet state, and also used to dissolve in glass or to fuse over a surface in glazing. The brown tints often seen in glazed objects are almost always the result of the decomposition of green glasses containing iron. The blue glasses, on the other hand, fade into white. The essential colouring materials are, for blue, cupreous copper, cobalt; red, haematite; white, tin. An entirely clear colourless glass was made in the XVIIIth Dynasty, but coloured glass was mainly used. After fusing a panful of coloured glass, it was sampled by taking pinches out with tongs; when perfectly combined it was left to cool in the pan, with modern optical glass. When cold the pan was chipped away, and the cake of glass broken up into convenient pieces, free of sediment and of
scum. A broken lump would then be heated to softness in the furnace; rolled out under a bar of metal, held diagonally across the roll; and when reduced to a rod of a quarter of an inch thick, it was heated and pulled out into even rods about an eighth of an inch thick. These were used to wind round glass vases, to form lips, handles, &c.; and to twist together for spiral patterns. Glass tube was similarly drawn out. Beads were made by winding thin threads of glass on copper wires, and the great bands around vases; and the bead to be twisted to any shape. The coating of beads can always be detected by (1) the little tails left at the ends, (2) the streaks, (3) the bubbles, seen with a magnifier. Roman glass beads are always drawn out, and nicked off hot, with striation lengthways; except the large opaque variegated beads which are coiled. Modern Venetian beads are similarly coiled. In the XXIIIrd Dynasty beads of a rich transparent Prussian blue glass were made, until the XXVIth. About the same time the eye beads, with white and brown eyes in a blue mass, also came in (P.A. 25-27, Plate XIII.).

Pottery (see fig. 112).—The earliest style of pottery is entirely hand made, without any rotary motion; the form being built up with a flat stick inside and the hand outside, and finally scraped and burnished in a vertical direction. The necks of vases were the first part finished with rotation, at the middle and close of the prehistoric age. Fully turned forms occur in the Ist Dynasty; but as late as the XIIth Dynasty the lower part of small vases is usually trimmed with a knife. In the earlier part of the prehistoric age there was a soft brown ware with haematite face, highly burnished. This was burnt mouth-down in the oven, and the ashes on the ground reduced the red haematite to black magnetic oxide of iron; some traces of carbolyn in the ash helped to rearrange the magnetite as a brilliant mirror-like surface of intense black. The lower range of jars in the oven had then black tops, while the upper ranges were entirely red. A favourite decoration was by lines of white clay slip, in crossing patterns, figures of animals, and, rarely, men. This is exactly of the modern Kabyle style in Algeria, and entirely disappeared from Egypt very early in the prehistoric times. Being entirely hand made, various oval, doubled and even square forms were readily shaped.

The later prehistoric age is marked by entirely different pottery, of a hard pink-brown ware, often with white specks in it, without any applied facing beyond an occasional pink wash, and no polishing. It is pigmented with red, black, and green. The céramettes otherwise only contain grays, cut in gravel or brick lined, and formerly roofed with poles and brushwood. The Ist to IIIrd Dynasties have left at Abydos large forts of brickwork, remains of two successive temples, and the royal tombs (see Asylos). Elsewhere are but few other monuments; at Wadi Maghdara in Sinai is a rock sculpture of Seremket of the Ist Dynasty in perfect state, at Giza is a group of tombs of a prince and retinue of the Ist Dynasty, and at Giza and Bét Khalaf are two large brick mastabas with extensive passages closed by trap-doors, of kings of the IIIrd Dynasty. The main structure of this age is the step-pyramid of Sakkara, which is a mastaba tomb with eleven successive coats of masonry, enlarging it to about 350 by 350 ft. and 200 ft. high. In the interior is sunk in the rock a chamber 22 x 23 ft. and 77 ft. high, with a granite sepulchre built in the floor of it, and various passages and chambers branching from it. The doorway of one room (now in Bard's Museum) was decorated with polychrome glazed tiles with the name of King Neterkhet. The complex original work and various alterations of it need thorough study, but it is now closed and research is forbidden.

The IVth to VIth Dynasties are best known by the series of pyramids (see Pyramid) in the region of Memphis. Beyond these towns, and the temples attached to them, there are very few fixed monuments; of Cheops and Pepi I. there are temple foundations at Abydos (p.n.), and a few blocks on other sites; of Neuserre (Rauser) there is a sun temple at Abustr; and of several kings there were tablets in Sinai, now in the Cairo Museum. A few tablets of the IXth Dynasty have been found at Sakkarra, and a tomb of a prince at Aissiat. Of the XIth Dynasty is the
Fig. 112.—Principal Types of Pottery of Ancient Egypt. (Scale 1:20.)
terrace-temple of Menthoth III. recently excavated at Thebes; also foundations of this king and of Sankhkeré at Abydos. In the XIIth Dynasty there is the celebrated red granite obelisk of Heliopolis, one of a pair erected by Senwosri (Seneusert I) in front of his temple which has now vanished. Another large obelisk of red granite, 41 ft. high, remains in the Fayum. The most important pictorial tombs of Beni Hasan belong to this age; the great princes appear to have largely quarried stone for their palaces, and to have cut the quarry in the form of a regular chamber, which served for the tomb chapel. These great rock chambers were covered with paintings, which show a large range of the daily life and civilization. The pyramids and temples of Senwosri II. and III. and Amenemhét III. remain at Ilaubn, Dahshûr and Hawâra. The latter was the celebrated Labyrinth, which has been entirely quarried away, so that only banks of chips and a few blocks remain. At the first of these sites is the most perfect early town, of which hundreds of houses still remain. Of Senwosri III. there are the forts and temples above the second cataract at Semna and Kummâ. Of the Hyksos age there are the scanty remains of a great fortified camp at Tell el-Yehudia.

In the XVIIIth to XXth Dynasties we reach the great period of monuments. Of Amásis (Achmès) and Amenophis I. there are but fragments left in later buildings; and of the latter a great quantity of sculpture has been recovered. The temple of Karnak already existed since the XIIth Dynasty or earlier, but the existing structure was begun under Tethmosis (Tahutmes) I., and of the two great pylons and one obelisk of his remains in place. He also built the simple and dignified temple of Medinet Habû at Thebes, which was afterward overshadowed by the grandiose work of Rameses III. The next generation—Tethmosis II. and Hatas-through—added to their father’s work; they also built another pylon and some of the existing chambers at Karnak, set up the great obelisks there and carved some colossi. The obelisks are exquisitely cut in red granite, each sign being sawn in shape by copper tools fed with emery, and the whole finished with a perfection of proportion and delicacy not seen on other granite work. One obelisk being overthrown and broken we can examine the minute treatment of the upper part, which was nearly a hundred feet from the ground. The principal monument of this period is the temple of Deir el Bahri, the funeral temple of Hatas-through, on which she recorded the principal event of her reign, the expedition to Punt. The erasures of her name by Tethmosis III., and reinsertions of names under later kings, the military scenes, and the religious groups showing the sacred kine of Hathor, all add to the interest of the remarkable temple. It stands on three successive terraces, rising to the base of the high limestone cliffs below. The rock-cut shrines of the temples of Amenophis II. and Tethmosis IV. are the most important, as they are the only larger monuments of this queen yet remaining. Tethmosis III. was one of the great builders of Egypt, and much remains of his work, at about forty different sites. The great temple of Karnak was largely built by him; most of the remaining chambers are his, including the beautiful botanical walls showing foreign plants. Of his work at Heliopolis there remain the obelisks of London and New York; and from Elephantine is the obelisk at Sion House. On the Nubian sites his work may still be seen at Amûda, Ellesia, Ibrim, Semna and in Sîrat Khâdem. Of Amenophis II. and Tethmosis IV. there are no large monuments, they being mainly known by additions at Karnak. The well known stele of the sphinx was cut by the latter king, to commemorate his dream there and his clearing of the sphinx from sand. Amenophis III. has left several large buildings of his magnificent reign. At Karnak the temple has a new front of great pylon, which was later used as the back of the hall of columns by Seti I. But three new temples at Karnak, that of Month (Mentu), of Mut and a smaller one, all are due to this reign, as well as the long avenue of sphinxes before the temple of Khons; these indicate that the present Rameside temple of Khons has superseded an earlier one of this king. The great temple of Luxor was built to record the divine origin of the king as son of Ammon; and on the western side of Thebes the funerary temple of Amenophis was an immense pile, of which the two colossi of the Theban plain still stand before the front of the site, where yet lies a vast tablet of sandstone 30 ft. high. The other principal buildings are the temples of Sedenga and of Sûlib in Nubia. Akhenaten has been so consistently eclipsed by the later kings who destroyed his work, that the painted pavement and the rock tablets of Tel el Amarna are largely in a ruinous state. In the Thirty-first Dynasty there were few inscriptions. Harmahib (Horemheb) resumed the work at Karnak, erecting two great pylons and a long avenue of sphinxes. The rock temple at Sâsilâ and a shrine at Jebel Adda are also his.

In the XIXth Dynasty the great age of building continued, and the remains are less destroyed than the earlier temples, because there were subsequently fewer scrupulous rulers to quarry them away. Seti I. greatly extended the national temple of Karnak by his immense hall of columns added in front of the pylon of Amenophis III. His funerary temple at Kurna is also in a fairly complete condition. The temple of Abydos is celebrated owing to its completeness, and the perfect condition of its sculptures, which render it one of the most interesting buildings as an artistic monument; and the variety of religious subjects adds to its importance. The very long reign and vast wealth of Egypt ensured the recovery of some sixty sites, more widely spread than that of any other king. Yet very few great monuments were originated by him; even the Ramessseum, his funerary temple, was begun by his father. Additions, appropriations of earlier works and scattered inscriptions are what mark this reign. The principal remaining buildings are parts of a court at Memphis, the second temple at Abydos, the six Nubian temples of Bet el-Wali, Jerf Hussein, Wadi es-Sehû, Derr, and the grandest of all—the rock-cut temple of Abu Simbel, with its neighbouring temple of Hathor. Mineptah has left few original works; the Osireum at Abydos is the only one of which much remains, his funerary temple having been destroyed as completely as he destroyed that of Amenophis III. The celebrated Israel stèle from this temple in his principal inscription. The rock shrines at Siâla are of small importance. There is no noticeable monument of the dozen troubled years of the end of the dynasty.

The XXth Dynasty opened with the great builder Rameses III. Probably he did not really exceed other kings in his activity; but as being the last of the building kings at the western side of Thebes, his temple has never been devastated for stone by the claims of later work. The whole building of Medinet Habû is about 500 ft. long and 160 wide, entirely the work of one reign. The sculptures of it are mainly occupied in the campaign of the king against the Libyans, the Syrians and the negroes, and are of the greatest importance for the history of Egypt and of the Mediterranean lands. Another large work was the clearance and rebuilding of much of the city of Tel el Yehudia, the palace hall of which contained the celebrated coloured tiles with figures of captives. At Karnak three temples, to Ammon, Khonsu and Mut, all belong to this reign. The blighted reigns of the later Ramesides and the priest-kings did not leave a single great monument, and they are only known by usurpations of the work of others. The Tanite kings of the XXIst Dynasty rebuilt the temple of their capital, but did little else. The XXIIInd Dynasty returned to monumental work. Sheshonk I. added a large wall at Karnak, covered with the record of his Judaean war. Osorkon (Usarsorn) I. built largely at Bubastis, and Osorkon II. added the great granite pylon there, covered with scenes of his festival; but at Thebes these kings did not build any new monuments. The Ethiopians (XXVth) dynasty built mainly in their capital under Mount Barkal, and Shibak and Tirhaka (Tahrak) also left chapels and a pylon at Thebes; and the latter added a great colonnade leading up to the temple of Karnak, of which one column is still standing.

Of the Saite kings there are very few large monuments. Their work was mainly of limestone and built in the Delta, and
hence it has been entirely swept away. The square fort of brick-work at Daphnae (q.v.) was built by Psammietichus I. Of Apries (Haa-ab-ra, Hophra) an obelisk and two monolithic shrines are the principal remains. Of Amasis (Aahmes) II. five great shrines are known; but the other kings of this age have only left minor works. The Persians kept up Egyptian monuments.

Darius I. quarried largely, and left a series of great granite decrees along his Suez canal; he also built the great temple in the oasis of Kharga.

The XXXth Dynasty renewed the period of great temples. Nektharheb built the temple of Behbã, now a ruinous heap of immense blocks of granite. Beside other temples, now destroyed, he set up the great west pylon of Karnak, and the pylon at Kharga. Nekhtneb built the Hathor temple and great pylon at Philae, and the east pylon of Karnak, beside temples elsewhere, now vanished. Religious building was continued under the Ptolemies and Romans; and though the royal impulse may not have been strong, yet the wealth of the land under good government supplied means for many places to rebuild their old shrines magnificently. In the Fayum the capital was dedicated to Queen Arsinoe, and doubtless Ptolemy rebuilt the temple, now destroyed. At Sharouia are remains of a temple of Ptolemy II. Dendera is one of the most imposing temples, giving a noble idea of the appearance of such work anciently. The body of the temple is of Ptolemy XIII., and was carved as late as the VXIIth (Caesarian), and the great portico was in building from Augustus to Nero. At Coptos was a screen of the temple of Ptolemy I. (now at Oxford), and a chapel still remains of Ptolemy XIII. Karnak was largely decorated; a granite cella was built under Philip Arrhidæus, covered with elaborate carving; a great pylon was added to the temple of Khonsu by Ptolemy III.; the inner pylon of the Ammon-temple was carved by Ptolemy VI. and IX.; and granite doorways were added to the temples of Mont and Mut by Ptolemy II. At Luxor the entire cella was rebuilt by Alexander. At Medinet Habû the temple of Tethmosis III. had a doorway built by Ptolemy X., and a forecourt by Antoninus. The smaller temple was built under Ptolemy X. and the emperors. South of Medinet Habû a small temple was built by Hadrian and Antoninus. At Esna the great temple was rebuilt and inscribed during a couple of centuries from Titus to Decius. At El Kab the temple dates from Ptolemy IX. and X. The great temple of Edfu, which has its enclosure walls and pylon complete, and is the most perfect example remaining, was gradually built during a century and a half from Ptolemy III. to XI. The monuments of Philæ begin with the wall of Nekhtneb; then began the great temple and the temple of Arthesofer (Arseniphs) is due to Ptolemy IV., that of Asclepius to Ptolemy V., that of Hathor to Ptolemy VI., and the great colonnades belong to Ptolemy XIII. and Augustus. The beautiful little riverside temple, called the "kiosk," was built by Augustus and inscribed by Trajan; and the latest building was the arch of Diocletian.

Farther south, in Nubia, the temples of Dabûd and Dakka were built by the Ethiopian Ergamese, contemporary of Ptolemy IV.; and the temple of Dendur is of Augustus. The latest building of the temple style is the White Monastery near Suhag. The external form is that of a great temple, with windows added along the top; while internally it was a Christian church. The modern dwellings in it have now been cleared out, and the interior admirably preserved and cleaned by a native Syrian Architect.

Beside the great monuments, which we have now noticed, the historical material is found on several other classes of remains. These are: 1) The royal tombs, which in the Vth, VIth, XVIIIth, XIXth and XXth Dynasties are fully inscribed; but as the texts are always religious and not historical, they are less important than many other remains. 2) The royal coffins and wrappings, which give information by the added graffiti recording their removals; 3) Royal tablets, which are of the highest antiquity; they form a very important class of historical documents. 4) Private tombs and tablets, which are in many cases biographical. 5) Papyri concerning daily affairs which throw light on history; or which give historic detail, as the great papyrus of Ramesses III., and the trials under Ramesses X. (6) The added inscriptions on buildings by later restorers, and alterations of names for misappropriation. 7) The statues which give the royal portraits, and sometimes historical facts. 8) The croocks, or rough notes of work accounts, and plans drawn on pieces of limestone or pottery. 9) The scarabs bearing kings' names, which under the Hyksos and in some other dark periods, are our main source of information. 10) The miscellaneous small remains of toilet objects, ornaments, weapons, &c., many of which bear royal names.

Every object and monument with a royal name will be found catalogued under each reign in Petrie's History of Egypt, 3 vols., the last editions of each being the fullest. (W. M. F. Petrie)

F. Chronology.—1. Technical.—The standard year of the Ancient Egyptians consisted of twelve months of thirty days each, with five epagemonal days, in all 365 days. It was thus an effective compromise between the solar year and the lunar month, and contrasts very favourably with the intricate and clumsy years of other ancient systems. The leap-year of the Julian and Gregorian calendars confers the immense benefit of a fixed correspondence to the seasons which the Egyptian year did not possess, but the uniform length of the Egyptian months is enviable even now. The months were grouped under three seasons of four months each, and were known respectively as the first, second, third and fourth month of the year, "inundation" or "verdure," "pro" or "seeds," "winter," and "harvest," "summer," the "five (days) over the year" being outside these seasons and the year itself, according to the Egyptian expression, and counted either at the beginning or at the end of the year. Ultimately the Egyptians gave names to the months taken from festivals celebrated in them, in order as follows:—Thoth, Paophi, Athyr, Chioak, Tobi, Mechîr, Phamôneth, Pharmâthi, Pachons, Payni, Epiph, Mesore, the epagemonal days being then called "the short year." In Egypt the agricultural seasons depend more immediately on the Nile than on the solar movements; the first day of the first month of inundation, i.e., nominally the beginning of the solar year, was the beginning of the year, and as the Nile commences to rise very regularly at about the date of the annual heliacal rising of the conspicuous dog-star Sothis (Sirius) (which itself follows extremely closely the slow retrogression of the Julian year), the primitive astronomers found in the heliacal rising of Sothis as observed at Memphis (on July 10 Julian) a very correct and useful starting-point for the seasonal year. But the year of 365 days lost one day in four years of the Gotthic or Julian year, so that in 1321 Egyptian years New Year's day fell a whole month too early according to the seasons, and in 1461 years a whole year was lost. This "Gothic period" or era of 1460 years, during which the Egyptian New Year's day travelled all round the Solar year, is recorded by Greek and Roman writers at least as early as the 1st century B.C. The epagemonal days appear on a monument of the Fifth Dynasty and in the very ancient Pyramid texts. They were determined by luck, and was the beginning of another civil year, the fact that, although they are named in journals and in festival lists, &c., where precise dating was needed, no known monument or legal document is dated in them. It is, however, quite possible that by the side of the year of 365 days a shorter year of 360 was employed for some purposes. Lunar months

1 Ten-day-periods as subdivisions of the month can be traced as far back as the Middle Kingdom. The day consisted of twenty-four hours, twelve of day (counted from sunrise to sunset) and twelve of night, it began at sunrise.
were observed in the regulation of temples, and lunar years, etc., have been suspected. To find uniformity in any department in Egyptian practice would be exceptional. By the decree of Canopus, Ptolemys III Euergetes introduced through the assembly of priests an extra day every fourth year, but this reform had no acceptance until it was reimposed by Augustus with the Julian calendar. Whether any earlier attempt was made to adjust the civil to the solar or Sothic year in order to restore the festivals to their proper places in the seasons temporarily or otherwise is a question of great importance for chronology, but at present it remains unanswered. Probably neither the Sothic nor any other era was employed by the ancient Egyptians, who dated solely by regnal years (see below). An inscription of Rameses II at Tanis is dated in the 400th year of the reign of the god Seth of Ombos, probably with reference to some religious ordinance during the rule of the Seth-worshipping Hyksos; Rameses II may well have celebrated its quatercentenary, but it is wrong to argue from this piece of evidence alone that an era of Seth was ever observed.

From the Middle Kingdom onward to the Roman period, the dates upon Egyptian documents are given in regnal years. On the oldest monuments the years in a reign were not numbered consecutively but were named after events; thus in the 1st Dynasty we find "the year of smiting the Anti-people," in the beginning of the 3rd Dynasty "the year of fighting and smiting the people of Lower Egypt." But under the 11th Dynasty there was a reset of property designation every two years and the custom, continuing (with some irregularities) for a long time, offered a uniform mode of marking years, whether current or past. Thus such dates are met with as "the year of the third time of numbering of a particular king, the next being designated as "the year after the third time of numbering." Under the 5th Dynasty this method was so much the rule that the words "of numbering" were commonly omitted. It would seem that in the course of the next dynasty the census began normally on the 1st of November (first month of inundation, i.e., 1st Thoth in the later calendar). In the latter case there would be a further consideration: was the portion of a calendar year following the accession of the new king counted to the last year of the outgoing king, or to the first year of the new king? In Dynasties I, IV-VIII, there are instances of the first mode (i), in Dynasties II, VI, (II), XII, XXVII, and onwards they follow the second (ii). It may be that the practice was not uniform in all documents even of the same age. In Ptolemaic times not only were Macedonian dates sometimes given in Greek documents, but there were certainly two native modes of dating current; down to the reign of Euergetes there was a "fiscal" dating in papyri, according to which the year began in Paophi, besides a civil dating probably from Thoth; later, all the dates in papyri start from Thoth.

The Macedonian year is found in early Ptolemaic documents. The fixed year of the Canopic decree under Euergetes (with 1st Thoth on Oct. 22) was never adopted. Augustus established an "Alexandrian" era with the fixed Julian year, retaining the Egyptian months, with a sixth epagomenal day every fourth year. The capture of Alexandria having taken place on the 1st of August 30 B.C., the era began nominally in 30 B.C., but it was not actually introduced till some years later, from which time the 1st Thoth corresponded with the 29th of August in the Julian year. The vague "Egyptian" year, however, continued in use in native documents for some centuries along with the Alexandrian "Ionian" year. The era of Diocletian dates from the 29th of August 284, the year of his reforms; later, however, the Christians called it the era of the Martyrs (though the persecution was not until 303), and it survived the Arab conquest. The dating by indication, i.e., Roman tax-censuses, taking place every fifteenth year, probably originated in Egypt, in A.D. 312, the year of the defeat of Maxentius. The indications began in Payni of the fixed year, when the harvest had been secured.

See F. K. Ginzell, Handbuch der mathematischen und technischen Chronologie, Bd. I. (Leipzig, 1906), and the bibliography in the following section.

1. Historical—As to absolute chronology, the assigning of a regnal year to a definite date B.C. is clear enough (except in occasional detail) from the conquest by Alexander onwards. Before that time, in spite of successive efforts to establish a chronology, the problem is very obscure. The materials for reconstructing the absolute chronology are of several kinds: (1) Regnal dates as given on contemporary monuments may indicate the lengths of individual reigns, but not with accuracy, as they seldom reach to the end of a reign and do not allow for co-regencies. Records of the time that has elapsed between two regnal dates in the reigns of different kings are very helpful; thus stelae from the Serapeum recording the ages of the Apis bulls with the dates of their birth and death have fixed the chronology of the XXVith Dynasty. Traditional evidence for the lengths of reigns exists in the Turin Papyrus of kings and in Manetho's history; unfortunately the papyrus is very fragmentary and preserves few reign-lengths entire, and Manetho's statements seem very untrustworthy, being known only from late excerpts. (2) The duration of a period may be calculated by generations or the probable average lengths of reigns, but such calculations are of little value, and the succession of generations even when the evidence seems to be full is particularly difficult to ascertain in Egyptian, owing to adoptions and the repetition of the same name even in one family of brothers and sisters. (3) Synchronisms in the histories of other countries furnish reliable dates. Greek, Persian, Babylonian, and Biblical variously place the XXVith Dynasty. Assyrian for the XXVith; less precise are the Biblical date of Rehoobam, contemporary with the invasion of Shishak (Sheshonk) in the XXIIInd Dynasty, and the date of the Babylonian and Assyrian kings contemporary with Amenhotep IV. in the XVIIIth Dynasty. The last, about 1400 B.C., is the earliest point to which such coincidences reach. (4) Astronomical data, especially the heliacal risings of Sothis recorded by dates of their celebration in the vague year. These are easily calculated on the assumption first that the observations were correctly made, secondly that the calendrical dates are in the year of 365 days beginning on 1st Thoth, and thirdly that this year subsequently underwent no readjustment or other alteration before the reign of Euergetes. The assumption may be a reasonable one, and if the results agree with probabilities as deduced from the rest of the evidence it is wise to adopt it; if on the other hand the evidence seems in any serious degree contrary to those results it may be surmised that the assumption is faulty in some particular. The harvest date referred to below helps to show that the first part of the assumption is justified.

The duration of the reigns in several dynasties is fairly well known from the incontrovertible evidence of contemporary monuments. The XXVith Dynasty, which lasted 159 years, is particularly clear, and synchronisms fix its regnal dates to the years B.C. within an error of one or two years at most. The lengths of several reigns in the XIIth, XVIIth and XIXth Dynasties are known, and the sum total for the XIIth Dynasty is preserved better than any other in the Turin Papyrus, which was written under the XIXth Dynasty. The succession and number of the kings are also ascertained for other dynasties, together with many regnal dates, but very serious gaps exist in the records of the Egyptian monuments, the worst being between the XIIth and the XVIIth Dynasties, between the Xith and the Vth, and at Dynasties I-III. For the chronology before the time of the XXVith Dynasty Herodotus's history

1 For the "sequence" dating (S.D.) used by archaeologists for the prehistoric period see above (§ Art and Archaeology, ad init. note).
CHRONOLOGY

EGYPT

is quite worthless. Manetho alone of all authorities offers a complete chronology from the Ist Dynasty to the XXXth. In the case of the six kings of the XXVIth Dynasty, Africanus, the best of his exponents, gives correct figures for five reigns, but attributes six instead of sixteen years to Necho; the other exponents have wrong numbers throughout. For the XXIth

Dynasty Manetho's figures are wrong wherever we can check them; the names, too, are seriously faulty. In the XVIIIth Dynasty he has too many names and few are clearly identifiable, while the numbers are incommensurable. In the XXII Dynasty the number of the kings is correct and many of the names can be justified, but the reign-lengths are nearly, if not quite, all wrong. The summations of years for the Dynasties XII and XVIII are likewise wrong. It seems, therefore, that the known texts of Manetho, serviceable as they have been in the reconstruction of Egyptian history, cannot be employed as a serious guide to the early chronology, since they are faulty wherever we can check them, even in the XXVIth Dynasty whose kings were so celebrated among the Greeks. There remain the astronomical data. Of these, the Sothic date furnished by a calendar in the Ebers Papyrus of the 4th year of Amenophis I. (when interpreted on the assumption stated above), and another at Elephantine of an uncertain year of Teshthoes III., tally well with each other (1550-1546, 1474-1470 B.C.) and with the Babylonian synchronism (not yet accurately determined) under Amenhotep IV. (Akhenaton). Another Sothic date of the 7th year of Senwosret III. on a Berlin papyrus from Kahun, similarly interpreted (1888-1878 B.C.), gives the XXII Dynasty a range from 2000 to 1788 B.C. This (discovered by L. Bordet in 1889) seems to offer a welcome ray, piercing the obscurity of early Egyptian chronology; guided by it the historian Ed. Meyer, and K. Sethe have framed systems of chronology in close agreement with each other, reaching back to the Ist Dynasty at about 3400 B.C. To Meyer is further due a calculation that the Egyptian calendar was introduced in 4241-4238 B.C. 1 Their results in general have been adopted by the "Berlin school," including Erman, Steindorff (in Baederker's Egypt) and Breastved in America. Nevertheless many Egyptologists are unwilling to accept the new chronology, the chief obstacle being that it almost short an interval for the six dynasties between the XXII and the XXVIIth. If the XXII Dynasty ended about 1750 B.C. and the XXVIIth

began about 1570 B.C., taking what seems to be the utmost interval that it permits, 220 years have to contain a crowd of kings of whom nearly 100 are already known by name from monuments and papyri, while fresh names are being added annually to the long list; the shattered fragments of the last columns in the Turin Papyrus show space for 150 or perhaps 160 kings of this period, apparently without reaching the XXVIth Dynasty. An estimate of 160 to 400 kings would therefore not be excessive. The dates that have come down to us are very few; the only ones known from the Hyksos period are of a 12th and a 33rd year. In the Turin Papyrus two reign-lengths of less than a year, seven others of less than five years each, one of ten years and one of thirteen seem attributable to the XXIIth and XXIII Dynasties. Probably most of the reigns were short, as Manetho also decidedly indicates. It is possible that the compiler of the Turin Papyrus, who excluded contemporary reigns in the period between the VIth and the XXII Dynasties, here admitted such; nor is a correspondingly large number of kings in so short a period without an analysis in history. Professor Petrie, however, thinks it best, while accepting the evidence of the Sirius date, to suppose further that a whole Sothic period of 1460 years had passed in the interval, making a total of 1660 years for the six dynasties in place of 220 years. This, however, seems greatly in excess of probability, and several Egyptologists familiar with excavation are willing to accept Meyer's figures on archaeological grounds. To the present writer it seems that Meyer's chronology provides a convenient working theory, but involves such an improbability in regard to the interval between the XXII and the XXVII Dynasties that the interpretation of the Sothic date on which it is founded must be viewed with suspicion until clear facts are found to corroborate it. Corroboration has been sought by Mahler, Sethe and Petrie in the dates of new mummies, of warlike and other expeditions, and of high Nile, but their evidence so far is too vague and uncertain to affect the question seriously. It is remarkable that no records of eclipses are known from Egyptian documents. The interesting date of the harvest at El Bersha, quoted by Meyer in Breasted, Records, i. p. 48, confirms the Sothic date for the XXII Dynasty in some measure, but it belongs to the same age, and therefore its evidence would be equally vitiated with the other by any subsequent alteration in the Egyptian calendar. Before the discovery of the Kahun Sothic date, Professor Petrie

1 Meyer makes XIII. overlap XV. (Hyksos), and XIV. (Xoite), contemporary with XVI. (Hyksos) and XVII. (Theban)." 2 Kramer (Early Dynastic Cemetery, p. 126), from his work in the prehistoric cemeteries, believes that Egypt was yet uncivilized at that early date to have performed this scientific feat.

put the end of the XXII Dynasty at 2265 B.C.; in 1884 even Meyer had suggested 1930 B.C. as its minimum date, thus allowing 400 years at the least for the period from the XXII Dynasty to the XVIIIth.

Beyond the XXII Dynasty estimates must again be vague. The spacing of the years on the Palermo stone has given rise to some calculations for the early dynasties. Others are grounded on the dates of certain operations which are likely to have
EGYPT [HISTORY]

taken place at particular seasons of the year so that they can be roughly calculated on the Sothic basis, others on Manetho's figures, average lengths of reigns, evidence of the Turin Papyrus, &c.

Table I. page 79 shows the chronology of the first nineteen dynasties, according to recent authorities, before and after the discovery of the Kahun Sothic date.

The dates of the earlier dynasties in this table are always intended to be only approximate; for instance, Meyer in 1904 allowed an error of 100 years either of excess or deficiency in the dates he assigned to the dynasties from the Xth upwards.

The other dynasties are dated as in Table II. by different authorities.

III. HISTORY

1. From the Earliest Times to the Moslem Conquest.

In the absence of a strict chronology, the epochs of Pharaonic history are conveniently reckoned in dynasties according to Manetho's scheme, and these dynasties are grouped into longer periods—the Old Kingdom (Dynasties I. to VIII.), including the Earliest Dynasties (I. to IIII.) and the Pyramid Period (Dynasties IV. to VI.); the Middle Kingdom (Dynasties IX. to XVII.), including the Heracleopolitan Dynasties (IX. to X.); and the Hyksos Period (Dynasties XV. to XVII.); the New Empire (Dynasties XVIII. to XX.); the Deltaic Dynasties (Dynasties XXI. to XXXI.), including the Saitic and Persian Periods (Dynasties XXXII. to XXXI.). The conquest by Alexander the Great in the Hellenistic age, comprising the periods of Ptolemaic and Roman rule.

The Prehistoric Age.—One of the most striking features of recent Egyptology is the way in which the earliest ages of the civilization, before the conventional Egyptian style was formed, have been illustrated by the results of excavation. Until 1895 there seemed little hope of reaching the records of those remote times, although it was plain that the civilization had developed in the Nile valley for many centuries before the IVth Dynasty, beyond which the earliest known monuments scarcely reached. Since that year, however, there has been a steady flow of discoveries in prehistoric and early historic cemeteries, and, partly in consequence of this, monuments already known, such as the annals of the Palermo stone, have been made articulate for the beginnings of history in Egypt.

It is probable that certain rudely chipped flints, so-called cobblets, in the alluvial gravels (formed generally at the mouth of wadis opening on to the Nile) at Thebes and elsewhere, are the work of primitive man; but it has been shown that such are produced also by natural forces in the rush of torrents. On the surface of the desert, at the borders of the valley, palaeolithic implements of well-defined form are not uncommon, and bear the marks of a remote antiquity. In some cases they appear to lie where they were chipped on the sites of flint factories. Geologists and anthropologists are not yet agreed on the question of whether races and conditions in the country have undergone large changes since these implements were deposited. As yet none have been found in such association with animal remains as would help in deciding their age, nor have any implements been discovered in rock-shelters or in caves.

Of neolithic remains, arrowheads and other implements are found in some numbers in the deserts. In the Fayum region, about the borders of the ancient Lake of Moeris and beyond, they are particularly abundant and interesting in their forms. But their age is uncertain; some may be contemporary with the advanced culture of the XIth Dynasty in the Nile valley. Definite history on the other hand has been gained from the wonderful series of "prehistoric" cemeteries excavated by J. de Morgan, Petrie, Reisner and others on the desert edgings of the cultivated alluvium of a number of wadis. The tombs revealed in them has been tabulated by Petrie in his Diospolis Parva; and the detailed publication of Reisner's unusually careful researches is bringing much new light on the questions involved, amongst other things showing the exact point at which the "prehistoric" series merges into the Isth Dynasty, for, as might be surmised, in many cases the prehistoric cemeteries continued in use under the earliest dynasties. The finest pottery, often painted but all hand-made without the wheel, belongs to the prehistoric period; so also do the finest flint implements, which, in the delicacy and exactitude of their form and flaking, surpass all that is known from other countries. Metal seems to be entirely absent from the earliest type of graves, but immediately thereafter copper begins to appear (bronze is hardly to be found before the XIth Dynasty). The paintings on the vases show boats driven by oars and sails rather squared, and the parts bear the star-like hieroglyphs. The cemeteries are found throughout Upper and Middle Egypt, but as yet have not been met with in the Delta or on its borders. This might be accounted for by the inhabitants of Lower Egypt having practised a different mode of disposing of the dead, or by their cemeteries being differently placed.

Tradition, mythology and later customs make it possible to recover a scrap of the political history of that far-off time. Menes, the founder of the Ist Dynasty, united the two kingdoms of Upper and Lower Egypt. In the prehistoric period, therefore, these two realms were separate. The capital of Upper Egypt was Nekheb, now represented by the ruins of El Kab, with the royal residence across the river at Nekhen (Hieropolis); that of Lower Egypt was at Buto (Puti or Dep) in the marshes, with the royal residence in the quarter called Peh. Nekhêbi, goddess of El Kab, represented the Upper or Southern Kingdom, which was also under the tutelage of the god Seth, the goddess Buto and the god Horus similarly presiding over the Lower Kingdom. The royal god in the palace of each was a hawk or Horus. The spirits of the deceased kings were honoured respectively as the jackal-headed spirits of Nekhen and the hawk-headed spirits of Pe. As we hear also of the "spirits of On" it is probable that Helioopolis was at one time capital of a kingdom. In after days the prehistoric kings were known as "Worshippers of Horus" and in Manetho's list they are the wisest "Dead," and gave "Heroes," being looked upon as intermediate between the divine dynasties and those of human kings. It is impossible to estimate the duration of the period represented by the prehistoric cemeteries; that the two kingdoms existed throughout unchanged is hardly probable.

According to the somatologist Elliott Smith, the most important change in the physical character of the people of Upper Egypt, in the entire range of Egyptian archaeology, took place at the beginning of the dynastic period; and he accounts for this by the mingling of the Lower with the Upper Egyptian population, consequent on the uniting of the two countries under one rule. From remains of the age of the IVth Dynasty he is able to define to some extent the type of the population of Lower Egypt as having a better cranial and muscular development than that of Upper Egypt, probably through immigration from Syria. The advent of the dynasties, however, produced a quickening rate of transformation in the country.

It is doubtful whether we possess any writing of the prehistoric age. A few names of the kings of Lower Egypt are preserved in the first line of the Palermo stone, but no annals are attached to them. Petrie considers that one of the kings buried at Abydos, provisionally called Nar-mer and whose real name may be Mer or Beza, preceded Menes; of him there are several inscribed records, notably a magnificent carved and inscribed
slate palette found at Hieraconpolis, with figures of the king and his vizier, war-standard and prisoners. To identify him with BesaU (Boeothos) of the 11th Dynasty runs counter to much archaeological evidence. Sethe places him after Menes and some would identify him with that king. Another inscribed palette from the pre-dynastic; it perhaps mentions a king named "Scorpion." The Old Kingdom.—The names of a number of kings attributable to the 1st Dynasty are known from their tombs at Abydos. Unfortunately, they are almost exclusively Horus titles αδικχ, in place of the personal names by which they were recorded in the lists of Abydos and Manetho; some were left, of the latter were found, and prove that the scribes of the New Kingdom were unable to read them correctly. Important changes and improvements took place in the writing even during the 1st Dynasty. The personal name of Menes is given by one only of many relics of a king whose Horus-name was Aha, "the Fighter." Doubts have been expressed about the identification with Menes, but it is strongly corroborated by the very archaic style of the remains. The name of Aha (Menes) was found in two tombs, one at Naqada north of Thebes which lies opposite the road to the Red Sea, the other at Abydos. Manetho makes the 1st Dynasty Thinite, this being the capital of the nome in which Abydos lay. Upper Egypt had preceded over Lower Egypt, and it seems clear that Menes came from the former and conquered the latter. According to tradition he founded Memphis which lay on the frontier of his conquest; probably he resided there as well as at Abydos; at any rate relics of one of the later kings of the 1st Dynasty have already been recognized in its vast necropolis. Of the eight kings of the 1st Dynasty, three—the fifth, sixth and seventh in the Ramesseid list of Abydos—are positively identified by tomb-remains from Abydos, and others are scarcely less certain. Two of the kings have also left tablets at the copper and turquoise mines of Wadi Maghara in Sinai. The royal tombs are built of brick, but one of them, that of Usaphis, had its floor of granite from Elephantine. They must have been filled with magnificent furniture and provisions of every kind, including annual record-tablets of the reigns, carved in ivory and ebony. From a fragment on the Palermo stone it is clear that material existed as late as the IVth Dynasty for a brief note of the height of the Nile and other particulars in each year of the reign of these kings.

The 11th Dynasty of Manetho appears to have been separated from the 1st even on the Palermo stone; it also was Thinite, and the tombs of several of its nine (2) kings were found at Abydos. The IIIr Dynasty is given as Memphis by Manetho. Two of the kings built huge mastaba-tombs at Bét Khallaf near Abydos, but the architect and learned scribe Imhotep designed for one of these two kings, named Zoser, a second and mightier monument at Memphis, the great step-pyramid of Sakkara. In Ptolemaic times Imhotep was deified, and the traditional importance of Zoser is shown by a forged grant of the Dodecachoenus to the eponym god Khnum, purporting to be from his reign, but in reality dating from the Ptolemaic age. With Snerfu, at the end of this dynasty, we reach the beginning of Egyptian history as it was known before the recent discoveries. Monuments and written records are henceforth more numerous and important, and the Palermo annals show a fuller scale of record. The events in the three years that are preserved include a successful raid upon the negroes, and the construction of ships and gates of cedar-wood which must have been brought from the forest of the Lebanon. Snerfu also set up a tablet at Wadi Maghara in Sinai. He built two pyramids, one of them at Médum in steps, the other, probably in the perfected form, at Dahahûr, both lying between Memphis and the Fayûm. Pyramids did not cease to be built in Egypt till the New Kingdom; but from the end of the IIIr to the Vth Dynasty is pre-eminently the time when the royal pyramid in stone was the chief monument left by each successive king. Zoser and Snerfu have already been noticed. The personal name enclosed in a cartouche is henceforth the commonest title of the king. We now reach the IVth Dynasty containing the famous names of Cheops (q.v.), Chephren (Khâfrîr) and Mycerinus (Memkœnû), builders respectively of the Great, the Second and the Third Pyramids of Giza. In the best art of this time there was a grandeur which was never again attained. Perhaps the noblest example of Egyptian sculpture in the round is a diodite statue of Chephren, one of several found by Mariette in the so-called Temple of the Sphinx. This "temple" proves to be a monumental gate at the lower end of the great causeway leading to the plateau on which the pyramids were built. A king Dedêbréf, between Cheops and Chephren, built a pyramid at Abu-Rosik. Shespeteskaf is one of the last in the dynasty. Tablets of most of these kings have been found at the mines of Wadi Maghara. In the neighbourhood of the pyramids there are numerous mastabas of the court officials with fine sculpture in the chapels, and a few decorated tombs from the end of this centralized dynasty of absolute monarchs are known in Upper Egypt. A tablet which describes Cheops as the builder of various shrines about the Great Sphinx has been shown to be a priestly forgery, but the Sphinx itself may have been carved out of the rock under the splendid rule of the IVth Dynasty.

The Vth Dynasty is said to be of Elephantine, but this must be a mistake. Its kings worshipped Rê, the sun, rather than Horus, as their ancestor, and the title Оа "son of the Sun" began to be written by them before the cartouche containing the personal name, while another "solar" cartouche, containing a name compounded with Rê, followed the title Εδ "king of Upper and Lower Egypt." Sahûr and the other kings of the dynasty built magnificent temples with obelisks dedicated to Rê, one of which, that of Neuserre at Abûsir, has been thoroughly explored. The marvellous tales of the Westcar Papyrus, dating from the Middle Kingdom, narrate how three of the kings were born of a priestess of Rê. The pyramids of several of the kings are known. The early ones are at Abûsir, and the best preserved of the pyramid temples, that of Sahûr, excavated by the German Orient-Gesellschaft, in its architecture and sculptured scenes has revealed an astonishingly complete development of art and architecture as well as of warlike enterprise by sea and land at this remote period; the latest pyramid belonging to the Vth Dynasty, that of Unas at Sakkâra, is inscribed with long ritual and magical texts. Exquisitely sculptured tombs of this time are very numerous at Memphis and are found throughout Upper Egypt. Of work in the traditional temples of the country no trace remains, probably because, being in limestone, it has all perished. The annals of the Palermo stone were engraved and added to during this dynasty; the chief events recorded for the time are gifts and endowments for the temples. Evidently priestly influence was strong at the court. Expeditions to Sinai and Puoni (Punt) are commemorated on tablets. The Vth Dynasty if not more vigorous was more articulate; inscribed tombs are spread throughout the country. The most active of its kings was the third, named Pepi or Phipus, from whose pyramid at Sakkara the capital, hitherto known as "White Walls," derived its later name of Memphis (Mïn-frt, Memph); a tombstone from Abydos celebrates the activity of a certain Una during the reigns of Pepi and his successor in organizing expeditions to the Sinai peninsula and south Palestine, and in transporting granite from Elephantine and other quarries. Herkhûf, prince of Elephantine and an enterprising leader of caravans to the south countries both in Nubia and the Libyan oases, flourished under Menaref and Pepi II. called Neferkêr. On one occasion he brought home a dwarf dancer from the Sudan, described as being like one brought from Puoni in the time of the fifth-dynasty king Ass; this drew from the youthful Pepi II. an enthusiastic letter which was engraved in full upon the façade of Herkhûf's temple. The reign of the fifth-dynasty king, begun early, lasted well over thirty years, a fact so long
remembered that even Manetho attributes to him ninety-four years; its length probably caused the ruin of the dynasty. The local princelings and monarchs had been growing in culture, wealth and power, and after Pepi II. an ominous gap in the monuments, pointing to civil war, leads to the end of the Old Kingdom. The VIIIth and IXth Dynasties are said to have been Memphite, but of them no record survives beyond some names of kings in the lists.

The Middle Kingdom.—The long Memphite rule was broken by the IXth and Xth Dynasties, of Heracleopolis Magna (Hnès) in Middle Egypt. Khethi or Achnhoeos was apparently a favourite name with the kings, but they are very obscure. They may have spread their rule by conquest over Upper Egypt and then overthrown the Memphite dynasty. The chief monuments of the period are certain inscribed tombs at Assiût; it appears that one of the kings, whose praenomen was Mikerê, supported by a fleet and army from Upper Egypt, and especially by the prince of Assiût, was restored to his paternal city of Heracleopolis, from which he had probably been driven out; his pyramid, however, was built in the old royal necropolis at Memphis. Later the princes of Thebes asserted their independence and founded the XIth Dynasty, which pushed its frontiers northwards until finally it occupied the whole country. Its kings were named Menthotpe, from Mont, one of the gods of Thebes; others, perhaps sub-kings, were named Enyot (Antef). They were buried at Thebes, whence the coffins of several were obtained by the early collectors of the 19th century. Nibhët Menthotpe I. probably established his rule over all Egypt. The funerary temple of Nebhepet Menthotpe III., the last but one of these kings, has been excavated by the Egypt Exploration Fund at Deir el Bahri, and must have been a magnificent monument. His successor Sankhkerë Menthotpe IV. is known to have sent an expedition by the Red Sea to Puoni.

The XIIth Dynasty is the central point of the Middle Kingdom, to which the decline of the Memphite and the rise of the Heracleopolite dynasty mark the transition, while the growth of Thebes under the XIIth Dynasty is its true starting-point. Monuments of the XIIth Dynasty are abundant and often of splendid design and workmanship, whereas previously there had been little produced since the VIth Dynasty that was not half barbarous. Although not much of the history of the XIIth Dynasty is ascertained, the Turin Papyrus and many dated inscriptions fix the succession and length of reign of the eight kings very accurately. The troubled times that the kingdom had passed through taught the long-lived monarchs the precaution of associating a competent successor on the throne. The nomarchs and the other feudal chiefs were inclined to strengthen themselves at the expense of their neighbours; a firm hand was required to hold them in check and distribute the honours as they were earned by faithful service. The tombs of the most favoured and wealthy princes are magnificent, particularly those of certain families in Middle Egypt at Beni Hassan, El Bersha, Assiût and Deir el Bahri, and it is probable that each had a court and organization within his nome like that of the royal palace in miniature. Eventually, in the reigns of Senwosri III. and Amenemhê III., the succession of strong kings appears to have centralized all authority very completely. The names in the dynasty are Amenemhê (Ammenemes) and Senwosri (formerly read Usertesen or Senusert). The latter seems to be the origin of the Sesostris (q.v.) and Sesois of the legends. Amenemhê I., the first king, whose connection with the previous dynasty is not known, reigned for thirty years, ten of them being in partnership with his son Senwosri I. He had to fight for his throne and then reorganize the country, removing his capital or residence from Thebes to a central situation near Lægh about 25 m. south of Memphis. His monuments are widespread in Egypt, the quarries and mines in the desert as far as Sinai bear witness to his great activity, and we know of an expedition which he made against the Nubians. The "Instructio of Ammenemhê to his son Senwosri," whether really his own or a later composition, refer to these things, to his care for his subjects, and to the ingratitude with which he was rewarded, an attempt on his life having been made by the trusted servants in his own camp.

The story of Sinhue is the true or realistic history of a soldier who, having overheard the secret intelligence of Amenemhê's death, fled to Palestine, and there became rich in the favour of the prince of the land; growing old, however, he successfully sued for pardon from Sesostris and permission to return and die in Egypt.

Senwosri I. was already the executive partner in the time of the co-regency, warring with the Libyans and probably in the Sudan. After Amenemhê's death he fully upheld the greatness of the dynasty in his long reign of forty-five years. The obelisk of Heliopolis is amongst his best-known monuments, and the burning of the Lake of Moeris (q.v.) must have been in progress in his reign. He built a temple far up the Nile at Wadi Halfâ and there set up a stela commemorating his victories over the tribes of Nubia. The fine tombs of Amen at Beni Hasan and of Hep zeset at Assiût belong to his reign. The pyramids of both father and son are at Lægh.

Amenemhê II. was buried at Dahshûr; he was followed by Senwosri II., whose pyramid is at Illahun at the mouth of the Fayyum. In his reign were executed the fine paintings in the tomb of Khennhotep at Beni Hasan, which include a remarkable scene of Semitic Bedouins bringing eye-paint to Egypt from the eastern deserts. In Manetho he is identified with Sesostris (see above), but Senwosri I., and still more Senwosri III., have a better claim to this distinction. The latter warred in Palestine and in Nubia, and marked the south frontier of his kingdom by a statue and stela at Semna beyond the Second Cataract. Near his pyramid was discovered the splendid jewelry of some princesses of his family (see JEWELRY AD INITI.). The tomb of Thothef at El Bersa, celebrated for the scene of the transport of a colossus amongst its paintings, was finished in this reign.

Amenemhê III. completed the work of Lake Moeris and began a series of observations of the height of the inundation at Semna which was continued by his successors. In his long reign of forty-six years he built a pyramid at Dahshûr, and at Hawârû near the Lake of Moeris another pyramid together with the Labyrinth which seems to have been an enormous funerary temple attached to the pyramid. His name was remembered in the Fayyum during the Graeco-Roman period and his effigy worshipped there as Perâ-marres, i.e. Pharaoh Marres (Marres being his praenomen graecized). Amenemhê IV.'s reign was short, and the dynasty ended with a queen Sekhefnrû (Scenomphâsis), whose name is found in the scantly remains of the Labyrinth. The tombs of the XIIth Dynasty numbered eight rulers and lasted for 213 years. Great as it was, it created no empire outside the Nile valley, and its most imposing monument, which according to the testimony of the ancients railed the pyramids, is now represented by a vast stratum of chips.

The history of the following period down to the rise of the New Empire is very obscure. Manetho gives us the XIIth (Diospolite) Dynasty, the XIVth (Xoite from Xois in Lower Egypt), the XVth and XVIth (Hykos) and the XVIIth (Diospolite), but his names are lost except for the Hykos kings. The Abydos tablet ignores all between the XIIth and XVIIIth Dynasties. The Turin Papyrus preserves many names on its shattered fragments, and the monuments are for ever adding to the list, but it is difficult to assign them accurately to their places. The Hykos names can in some cases be recognized by their foreign aspect, the peculiar style of the scarabs on which they are engraved or by resemblances to those recorded in Manetho. The kings of the XVIIth Dynasty too are generally recognizable by the form of their name and other circumstances. Manetho indicates marvellous crowding for the XIIth and XIVth Dynasties, but it seems better to suggest a total duration of 300 or 400 years for the whole period than to adopt Meyer's estimate of about 210 years (see above, CHRONOLOGY).

Amongst the kings of the XIIIth Dynasty (including perhaps the XIVth), not a few are represented by granite statues of colossal size and fine workmanship, especially at Thebes and Tanis, some by architectural fragments, some by graffiti on the
rocks about the First Cataract. Some few certainly reigned over all Egypt. Sekhhotep (Sekhotep, Σωκήπτος) is a favourite name, no doubt to be connected with the god of the Fayum. Several of the Theban kings named Antef (Enyot) must be placed here rather than in the XIXth Dynasty. The monuments of his wife degrading a monarch who had sided with his enemies was found at Coptos engraved on a doorway of Senwosri I.

In its divided state Egypt would fall an easy prey to the foreigner. Manetho says that the Hyksos (γεχος) gained Egypt without a blow. Their domination must have lasted a considerable time, the Rhind mathematical papyrus having been copied in the thirty-third year of a king of the Nineteenth Dynasty. The monuments of this later king, which gives scars of the Hyksos kings are found throughout Upper and Lower Egypt; those of Khian somehow spread as far as Crete and Bagdad. The Hyksos, in whom Josephus recognized the children of Israel, worshipped their own Syrian deity, identifying him with the Egyptian god Seth, and endeavoured to establish his cult throughout Egypt to the detriment of the native gods. It is to be hoped that definite light may one day be forthcoming on the whole of this critical episode which had such a profound effect on the character and history of the Egyptian people. The spirited overthrow of the Hyksos ushered in the glorious ages in arts and arms which marked the New Empire. The XVIIth Dynasty probably began the struggle, at first as semi-independent kings at Thebes. Seqenenre is here a leading name; the mummy of the third Seqenenre, the earliest in the great find of royal mummies at Deir el Bahri, shows the head frightfully hacked and split, perhaps in a battle with the Hyksos.

The New Empire. The period new 1 is generally attached to this period, and "empire" instead of "kingdom" marks its wider power. The glorious XVIIIth Dynasty seems to have been closely related to the XVIIth. Its first task was to crush the Hyksos power in the north-east of the Delta; this was fully accomplished by its founder Ahmosi (dailgectically Ahmâsi, Amās or Amās I) capturing their great stronghold of Avaris. Amasis next attacked them in S.W. Palestine, where he captured Sharhenu after a siege of three years. He fought also in Syria and in Nubia, besides overcoming furious opposition in his own land. The principal source for the history of this time is the biographical inscription at El Kab of a namesake of the king, Ahmosi son of Abarra, a sailor and warrior whose exploits extend to the reign of Tuthmosis I. Amenophis I. (Amenhotep), succeeding Amasis, fought in Libya and Ethiopia. Tuthmosis I. (c. 1540 B.C.) was perhaps of another family, but obtained his title to the throne through his wife Ahmosis. After some thirty years of settled rule uninterrupted by revolt, Egypt was now strong and rich enough to indulge to the full its new taste for war and lust of conquest. It had become essentially a military state. The whole of the administration was in the hands of the king with his vizier and other court officials; no trace of the feudalism of the Middle Kingdom survived. Tuthmosis thoroughly subdued Cush, which had already been placed under the government of a viceroy. This province of Cush extended from Napata just below the Fourth Cataract on the south to El Kab in the north, so that it included the first three nomes of Upper Egypt, which agriculturally were not greatly superior to Nubia. Turning next to Syria, Tuthmosis carried his arms as far as the Euphrates. It is possible that his predecessor had also reached this point, but no record survives to prove it. These successful campaigns were probably not very costly, and prisoners, plunder and tribute poured in from them to enrich Egypt. Tuthmosis I. made the first of those great additions to the temple of the Theban Ammon at Karnak by which the Pharaohs of the Empire rendered it by far the greatest of the existing temples in the world. The temple of Deir el Bahri also was designed by him. Towards the end of his reign, his elder sons being dead, Tuthmosis associated Hatshepsut, his daughter by Ahmosi, with himself upon the throne. Tuthmosis I. was the first of the long line of kings to be buried in the Valley of the Tombs of the Kings of Thebes. At his death another son Tuthmosis II. succeeded as the husband of his half-sister, but reigned only two or three years, during which he warred in Nubia and placed Tuthmosis III, his son by a concubine Esi, upon the throne beside him (c. 1500 B.C.). After her husband's death the ambitious Hatshepsut assumed the title of queen regnant. Upon her monuments she wears the masculine garb and aspect of a king though the feminine gender is retained for her in the inscriptions. On some monuments of this period her name appears alone, on others in conjunction with that of Tuthmosis III., while the latter again may appear without the queen's; but this extraordinary woman must have had a great influence over her stepson and was the acknowledged ruler of Egypt. Tuthmosis, to judge by the size of his mummy and the chronology of his reign, was already a grown man, yet no sign of the immense powers which he displayed later has come down to us from the joint reign. Hatshepsut cultivated the arts of peace. She restored the worship in those temples of Upper and Lower Egypt which had not yet recovered from the religious oppression and neglect of the Hyksos. She completed and decorated the temple of Deir el Bahri, embellishing its walls with scenes calculated to establish her claims, representing her divine origin and upbringing under the protection of Ammon, and her association on the throne by her human father. The famous sculptures of the great expedition by water to Puimin, the land of incense on the Somali coast, are also here, with many others. At Karnak Hatshepsut laboured chiefly to complete the works projected in the reigns of Tuthmosis I. and II., and set up two obelisks in front of the entrance as it then was. One of these, still standing, is the most brilliant ornament of that wonderful temple. A date of the twenty-second year of the reign has been found at Sinai, and counted from the beginning of the co-regency with Tuthmosis I. Not much later, in his twenty-second year, Tuthmosis III. is reigning alone in full vigour. While she lived, the personality of the queen secured the devotion of her servants and held all ambitions in check. Not long after her death there was a violent reaction. Prejudice against the rule of a woman, particularly one who had made her name and figure so conspicuous, was probably the cause of this outbreak, and perhaps sought justification in the fact that, however complete was her right, she had in some degree usurped a place to which her stepson (who was also her nephew) had been appointed. Her cartouches began to be defaced or her monuments hidden up by other buildings, and the same rage pursued some of her most faithful servants in their tombs. But the beauty of the work seems to have restrained the hand of the destroyer. Then came the religious fanaticism of Akhenaten, mutilating all figures of Ammon and all inscriptions containing his name; this peacefully left the exquisite monuments of Hatshepsut; and the restorers of the XIXth Dynasty, refusing to recognize the legitimacy of the queen, had no scruples in replacing her names by those of the associate kings Tuthmosis I., II. or III. These acts of vandalism took place throughout Egypt, but in the distant mines of Sinai the cartouches of Hatshepsut are untouched. In the royal lists of Seti I. and Rameses II. Hatshepsut has no place, nor is her reign referred to on any later monument.

The immense energy of Tuthmosis III. now found its outlet in war. Syria had revolted, perhaps on Hatshepsut's death, but by his twenty-second year the monarch was ready to lead his army against the rebels. The revolt, headed by the city of Kadesh on the Orontes, embraced the whole of western Syria. The movements of Tuthmosis in this first campaign, including a battle with the Syrian chariots and infantry at Megido and the capture of that city, were chronicled from day to day, and an extract from this chronicle is engraved on the walls of the sanctuary of Karnak, together with a brief record of the subsequent expeditions. In a series of Wars of Tuthmosis III. 1 The history of Hatshepsut has been very obscure, and the mutilations of her cartouches have been variously accounted for. Recent discoveries by M. Legrain at Karnak and Prof. Petrie at Thebes has limited the fulfilment of the cartouches. The text has followed M. Naville's guidance in his biography of the queen (in T. M. Davis, The Tomb of Hatshepsut, London, 1906, pp. 1 et seq.), made with very full knowledge of the complicated data.
of five carefully planned campaigns he consolidated his conquests in southern Syria and secured the ports of Phoenicia (q.v.). Kadesh fell in the sixth campaign. In the next year Tethmosis revisited the Phoenician ports, chastised the rebellious and received the tribute of Syria, all the while preparing for further advance, which did not take place until another year had gone by. Then, in the thirty-third year of his reign, he marched through Kadesh, fought his way to Carchemish, defeated the forces that opposed him there and crossed over the Euphrates into the territory of the king of Mitanni. He set up a tablet by the side of that of Tethmosis I. and turned southward, following the river as far as Niy. Here he stayed to hunt a herd of 120 elephants, and then, marching westwards, received the tribute of Naharina and gifts from the Hittites in Asia Minor and from the king of Babylon. In all he fought seventeen campaigns in Syria until the spirit of revolt was entirely crushed in a second capture of Kadesh. The wars in Libya and Ethiopia were of less moment. In the intervals of war Tethmosis III. proved to be a wonderfully efficient administrator, with his eye on every corner of his dominions. The Syrian expeditions occupied six months in most of his best years, but the remaining time was spent in activity at home, repressing robbery and injustice, rebuilding and adorning temples with the labour of his captives and the plunder and tribute of conquered chiefs, or designing with his own hand the gorgeous sacred vessels of the sanctuary of Ammon. In his later years some expeditions took place into Nubia. Tethmosis died in the fifty-fourth year of his reign. His mummy, found in the cachette at Deir el Bahri, is said to be that of a very old man. He was the greatest Pharaoh in the New Empire, if not in all Egyptian history.

Tethmosis III. was succeeded by his son Amenophis II., whom he had associated on the throne, at the end of his reign. One of the first acts of the new king was to lead an army into Syria, where revolt was again rife; he reached and perhaps crossed the Euphrates and returned home to Thebes with seven captive kings of Tikhi and much spoil. The kings he sacrificed to Ammon and hanged six bodies on the walls, while the seventh was carried south to Napata and there exposed as a terror to the Ethiopians. Amenophis reigned twenty-six years and left his throne to his son Tethmosis IV., who is best remembered by a granite tablet recording his clearance of the Great Sphinx. He also warred in northern Syria and in Cush. His son Amenophis III., c. 1400 B.C., was a mighty builder, especially at Thebes, where his reign marks a new epoch in the history of the great temples, Luxor being his creation, while avenues of rams, pylons, &c., were added on a vast scale to Karnak. He married a certain Taia, who, though apparently of humble parentage, was held in great repute by her husband, as afterwards by her son. Amenophis III. warred in Ethiopia, but his sway was long unquestioned from Napata to the Euphrates. Small objects with his name and that of Taia are found on the mainland and in the islands of Greece. Through the fortunate discovery of cuneiform tablets deposited by his successor in the archives at Tell el-Amarna, we can see how the rulers of the great kingdoms beyond the river, Mitanni, Assyria and even Babylonia, corresponded with Amenophis, gave their daughters to Amenophis in marriage, and congratulated themselves on being in his friendship. The king of Cyprus too courted him; while within the empire the descendants of the Syrian dynasts conquered by his father, having been educated in Egypt, ruled their paternal possessions as the abject slaves of Pharaoh. A constant stream of tribute poured into Egypt, sufficient to defray the cost of all the splendid works that were executed. Amenophis caused a series of large scarabs inscribed with his name and parentage of his queen Taia, found in the varying texts commemorating like medals the boundaries of his kingdom, his secondary marriage with Gilukhipa, daughter of the king of Mitanni, the formation of a sacred lake at Thebes, a great hunt of wild cattle, and the number of lions the king slew in the first ten years of his reign. The colossi known to the Greeks by the name of the Homeric hero Memnon, which look over the western plain of Thebes, represent this king and were placed before the entrance of his funerary temple, the rest of which has disappeared. His palace lay farther south on the west bank, built of crude brick covered with painted stucco. Towards the end of his reign of thirty-six years, Syria was invaded by the Hittites from the north and the people called the Khubir from the eastern desert; some of the kinglets conspired with the invaders to overthrow the Egyptian power, while those who remained loyal sent appeals to the Hittites to intercede with the Persians.

Amenophis IV., son of Amenophis III. and Taia, was perhaps the most remarkable character in the long line of the Pharaohs. He was a religious fanatic, who had probably been high priest of the sun-god at Heliopolis, and had come to view the sun as the visible source of life, creation, growth and activity, whose power was demonstrated in foreign lands almost as clearly as in Egypt. Thrusting aside all the multitudinous deities of Egypt and all the mythology even of Heliopolis, he devoted himself to the cult of the visible sun-disk, applying to it as its chief name the hitherto rare word Aton, meaning "sun"; the traditional divine name Harakht (Horus of the horizon), given to the hawk-headed sun-god of Heliopolis, was however allowed to subsist and a temple was built at Karnak to this god. The worship of the other gods was officially recognized until his fifth year, but then a sweeping reform was initiated by which apparently the new cult alone was permitted. Of the old deities Amenophis represented by far the weakest and most powerful interests, and against this long favoured deity the Pharaoh hurled himself with fury. He changed his own name from Amenhotep, "Amon is satisfied," to Akhenaton, "pious to Aton," erased the name and figure of Ammon from the monuments, even where it occurred as part of his own father's name, abandoned Thebes, the magnificent city of Ammon, and built a new capital at El Amarna in the plain of Hesperopolis, on a virgin site upon the edge of the desert. This was a large area around he dedicated to Aton in the sixth year, while splendid temples, palaces, houses and tombs for his god, for himself and for his courtiers were rising around him; apparently also this "son of Aton" swore an oath never to pass beyond the boundaries of Aton's special domain. There are signs also that the polytheistic word "gods" was obliterated on many of the monuments, but other divine names, though almost entirely excluded from Akhenaton's work, were left untouched where they already existed. In all local temples the worship of Aton was instituted. The confiscated revenues of Ammon and the tribute from Syria and Cush provided ample means for adorning Akhetaton, "the horizon of Aton," the new capital, and for richly rewarding those who adopted the Aton teaching fervently. But meanwhile the political needs of the empire were neglected; the dangers which threatened it at the end of the reign of Amenophis III. were never properly met; the dynasty in Syria were at war amongst themselves, intriguing with the great Hittite advance and with the Khubir invaders. Those who relied on Pharaoh and remained loyal as their fathers had done sent letter after letter appealing for aid against their foes. But though a general was despatched with some troops, he seems to have done more harm than good in misjudging the quarrels. At length the tone of the letters becomes one of despair, in which Pharaoh of Egypt is the only resource left for the ailing empire of the Egyptian cause. Before the end of the reign Egyptian rule in Syria had probably ceased altogether. Akhenaton died in or about the seventeenth year of his reign, c. 1350 B.C. He had a family of daughters, who appeared constantly with him in all ceremonies, but no son. Two sons-in-law followed him with brief reigns; but the second, Tutankhaton, soon changed his name to Tutenkhmard, and, without abandoning Ekhaton entirely, began to rebuild Karnak its former ampleness. The statues dedicated to Ammon. Akhenaton's reform had not reached deep amongst the masses of the population; they probably retained all their old religious customs and superstitions, while the priesthoods throughout the country must have been fiercely opposed to the heretic's work, even if silenced during his lifetime by force and bribes. One more adherent of his named Ay, a priest, ruled for a short time, but now Aton was only one of many
god. At length a general named Harmhab, who had served
under Akhenaton, came to the throne as a whole-hearted supporter
of the old religion; soon Aton and his royal following suffered the
fate that they had imposed upon Ammon; their monuments
were destroyed and their names and figures erased, while those
of Ammon were restored. From the time of Rameses II. onwards
the years of the reigns of the heretics were counted to Harmhab,
and Akhenaton was described as "that criminal of Akhetaton.""
Harmhab had to bring order as a principal man into the long-
neglected administration of the country and to suppress the
extractions of the official classes by severe measures. His laws to
this end were engraved on a great stela in the temple of Karnak,
of which sufficient remains to be without my hand, while the prosperity of the succeeding reigns shows how well he realized the necessities of the state. He probably began also to
re-establish the prestige of Egypt by military expeditions in the
surrounding countries.

Harmhab appears to have legitimated his rule by marriage
to a royal princess, but it is probable that Rameses I., who suc-
cceeded as founder of the XIXth Dynasty, was not closely
related to him. Rameses in his brief reign of two years
planned and began the great colonnaded hall of Karnak, proving that he was a man of great ideas, though
probably too old to carry them out; this task he left to his son
Seti I., who reigned one year with his father and on the latter's
death was ready at once to subdue the Bedouin Shasu, who had
invaded Palestine and withheld all tribute. This task was quickly
accomplished and Seti pushed onward to the Lebanon. Here
cedars were felled for him by the Syrian princes, and the Phoe-
nicians paid homage before he returned home in triumph. The
Libyans also had to be dealt with, and afterwards Seti advanced
again through Palestine, ravaged the land of the Amorites
and came into conflict with the Hittites. The latter, however, were now
firmly established in the Orontes valley, and a treaty with Muta-
allu, the king of Kheta, reigning far away in Cappadocia, probably
ended the wars of Seti. In his ninth year he turned his attention
to the gold mines in the eastern desert of Nubia and improved the
road thither. Meanwhile the great work at Karnak projected
by his father was going forward, and throughout Egypt the
injuries done to the monuments by Akhenaton were thoroughly
repaired; the erased inscriptions and figures were restored, not
without many blunders. Seti's temple at Abydos and his
galleried tomb in the Valley of the Tombs of the Kings stand out
as the most splendid examples of their kind in design and in
Rameses II. succeeded Rameses I at an early age
and reigned sixty-six years, during which time
Rameses II. paid much attention to the Delta, which had been
neglected until the days of Seti I., and resided there constantly;
the temple of Tanis must have been greatly enlarged and adorned
in his reign. He also added much to the height of the Theban colonnade
which he had erected in his mortuary temple of the Ramesseum.
Towards the end of the long reign the vigilance and energy of
the old king diminished. The military spirit awakened in the
struggle with the Hyksos had again departed from the Egyptian
nation; mercenaries from the Sudan, from Libya and from the
northern nations supplied the armies, while foreigners settled in
the rich lands of the Delta and harried the coasts. It was
not too soon when the movements of the nations that so frequently
occurred in the ancient world were about to be particularly active.
Meinephtah, c. 1225 B.C., succeeding his father Rameses II., had
to fight many battles for the preservation of his kingdom
and empire. Apparently most of the fighting was finished by
the fifth year of his reign; in his mortuary temple at Thebes he set
up a stela of that date recording a great victory over the Libyan
immigrants and invaders, which rendered the much harried
land of Egypt safe. The last lines picture this condition with
the crushing of the surrounding tribes. Libya was wasted, the
Hittites pacified, Canaan, Ashkelon (Ascalon), Gezer, Yenoam
sacked and plundered: "Israel is desolate, his seed is not,
Khur (Palestine) has become a widow (without protector) for Egypt."
The Libyans are accompanied by allies whose names,
Sherden, Shekelesh, Ekwesh, Lukku, Teresh, suggest identifica-
tions with Sardinians, Sicels, Achaeans, Lydians and Tyrenell
or Etruscans. The Sherden were princes, and the Shekelesh,
were Phoenicians, and are distinguished by their remarkable helmets
and apparently body armour of metal. The Lukku are certainly
the same as the Lydians. Probably they were also sea-rovers
from the shores and islands of the Mediterranean, who were
willing to leave their ships and join the Libyans in raids on the
rich lands of Egypt. Meinephtah was one of the most unconscion-
able usurpers of the monuments of his predecessors, including
those of his own father, who, it must be admitted, had set him
the example. The coarse cutting of his cartouches contrasts with
the splendid finish of the Middle Kingdom work which they
disfigure. It may be questioned whether it was due to a wave
of enthusiasm amongst the priests and people, leading them to
redegrade the monuments in the name of their deliverer, or a
somewhat insane desire of the king to perpetuate his own memory
in a singularly unfortunate manner. Meinephtah, the thirteenth
son in the huge family of Rameses, must have been old when he
ascended to the throne; and after the first year of his reign he
gave way, and he was followed by a quick succession of inglorious
rulers, Seti II., the queen Tuoser, Amememese, Siptah; the names
of the last two were erased from their monuments.

A great papyrus written after the death of Rameses III. and
recording his gifts to the temples briefly reviews the conditions
of these troublous times. "The land of Egypt was
in the hands of chiefs and rulers of towns, great and
small slaying each other; afterwards a certain Syrian
made himself chief; he made the whole land tributary before him;
he united his companions and plundered their property
(i.e. of the other chiefs). They made the gods like men, and no
offerings were presented in the temples. But when the gods
inclined themselves to peace...they established their son
Setenekhot (Setnekht) to be ruler of every land." Of the Syrian
occupation we know nothing further. Setenekhot, c. 1200 B.C.,
had a very short reign and was not counted as legitimate, but
he established a lasting dynasty (probably by conciliating the
priesthood). He was father of Rameses III., who revived the
glories of the empire. The dangers that menaced Egypt now
were similar to those which Meinephtah had to meet at his accession.
Again the Libyans and the "peoples of the sea" were acting
in concert. The latter now comprised Paleset (the Cretans,
ancestors of the Philistines), Thelkel, Shekelesh, Denyen
(Dananii) and Wesheh; they had invaded Syria from the
Minor, reaching the Euphrates, destroying the Hittite cities
and progressing southwards, while their ships gathered plunder

___
from the coasts of the Delta. This fleet joined the Libyan invaders, but was overthrown with heavy loss by the Egyptians, in whose ranks there actually served many Sardanaphal and kings of the Sardinian school. The Egyptian itself was clear of enemies; but the chariots and warriors of the Philistines and their associates were advancing through Syria, their families and goods following in ox-carts, and their ships accompanying them along the shore. Rameses led out his army and fleet against them and struck them so decisive a blow that the migrating swarm submitted to his rule and paid him tribute. In his eleventh year another Libyan invasion had to be met, and his success in Palestine forcibly asserted. His vigour was equal to all these emergencies and the later years of his reign were spent in peace. Rameses III., however, was not a great ruler. He was possessed by the spirit of decadence, imitative rather than originating. It is evident that Rameses II. was the model to which he endeavoured to conform, and he did not attempt to preserve himself from the weakening influences of priestcraft. To the temples he not only restored the property which had been given to them by former kings, but he also added greatly to their wealth; the Theban Ammon naturally received by far the greatest share, more than those of all the other gods together. The land held in the name of different deities is estimated at about 15% of the whole of Egypt; various temples of Ammon owned two-thirds of this, Re of Heliopolis and Ptah of Memphis being the next in wealth. His palace was at Medinet Habu on the west bank of Thebes in the south quarter; and here he built a great temple to Ammon, adorned with scenes of victories and richly provided with divine offerings. Although Egypt probably was prosperous on the whole, there was undoubtedly great distress amongst certain portions of the population. We read in a papyrus of a strike of starving labourers in the Theban necropolis who would not work until corn was given to them, and apparently the government storehouse was empty at the time, perhaps in consequence of a bad Nile. Shortly before the death of the old king a plot in the harem to assassinate him, and apparently to place one of his sons on the throne, was discovered and its investigation ordered, leading after his death to the condemnation of many high-placed men and women. Nine kings of the name of Rameses now followed each other ingloriously in the space of about eighty years to the end of the XXth Dynasty, the power of the high priests of Ammon ever growing at their expense. At this time the Theban necropolis was being more systematically robbed than ever before. Under Rameses IX. an investigation took place which revealed all the royal tombs before the western cliffs had been completely ransacked and the mummies burnt. Three years later the Valley of the Tombs of the Kings was attacked and the sepulchres of Seti I. and Rameses II. were robbed.

The authority of the last king of the XXth Dynasty, Rameses XII., was shadowy. Hirmor, the high priest in his reign, gradually gathered into his own hands all real power, and succeeded him at Thebes, c. 1100 B.C., while a prince at Tanis named Smendes (Esbutenti) founded a separate dynasty in the Delta (Dynasty XXII). From this period dates a remarkable papyrus containing the report of an envoy named Unamun, sent to Syria by Hirmor to obtain cedar timber from Byblus. He took with him an image of Ammon to bestow life and health on the prince of Byblus, but apparently no other provision for the journey or for the negotiations beyond a letter of recommendation to Smendes and a little gold and silver. Smendes had trading ships in the Phoenician ports, but even his influence was not greater than that of other commercial or pirate centres, while Hirmor was of no account except in so far as he might pay well for the cedar wood he required. Unamun was robbed on the voyage, the prince of Byblus rebuffed him, and when at last the latter agreed to provide the timber it was only in exchange for substantial gifts hastily sent for from Egypt (including rolls of papyrus) and the prince of Byblus could not refuse. This, however, seems to have acknowledged to some extent the divinity of Ammon and the debt owed by Phoenicia to Egyptian culture, and pitted the many misfortunes of Unamun. The narrative shows the feehlessness of Egypt abroad. The Tanite line of kings had generally had the overwhelming of the high princes of Thebes and the descendants of Hirmor, however, sometimes by marriage with princesses of the other line, could assume cartouches and royal titles, and in some cases perhaps ruled the whole of Egypt. Ethiopia may have been ruled with the Thebais, but the records of the time are very scanty. Syria was wholly lost to Egypt. The mummies from the despoiled tombs of the kings were the object of much anxious care to the kings of this dynasty; after being removed from one tomb to another, they were finally deposited in a shaft near the Temple of Deir el Bahri, where they remained for nearly three thousand years, until the demand for antiquities at last brought the plunderer once more to their hiding-place; eventually they were all secured for the Cairo museum, where they may now be seen.

Libyan soldiers had long been employed in the army, and their military chiefs settled in the large towns and acquired wealth and power, while the native rulers grew weaker and weaker. The Tanite dynasty may have risen from a Libyan stock, though there is nothing to prove it; the XXIIInd Dynasty are clearly from their names of foreign extraction, and their genealogy indicates distinctly a Libyan military origin in a family of rulers of Heracleopolis Magna, in Middle Egypt. Sheshonk (Shishak) I., the founder of the dynasty, c. 950 B.C., seems to have fixed his residence at Bubastis in the Delta, and his son married the daughter of the last king of the Tanite dynasty. Heracleopolis Magna was then a great and wealthy city, with a scene of the festival of Isis, with the Nebet, the celebration of the year of the New Year. Sheshonk secured Thebes, making one of his sons high priest of Ammon, and whereas Solomon appears to have dealt with a king of Egypt on something like an equal footing, Sheshonk re-established Egyptian rule in Palestine and Nubia, and his expedition in the fifth year of Rehoboam subdued Israel as well as Judah, to judge by the list of city names which he inscribed on the wall of the temple of Karnak. Osorkon I. inherited a prosperous kingdom from his father, but no further progress was made. It required a strong hand to curb the Libyan chieftains, and divisions soon began to show themselves in the kingdom. The XXIIInd Dynasty lasted through many generations; but there were rival kings, and M. Leigrain thinks that he has proof that the XXIIIrd Dynasty was contemporaneous with the end of the XXIIInd. The kings of the XXIIIrd Dynasty had little hold upon the subject princes, who spent the money raised in the country on adventures amongst themselves. A native kingdom had meanwhile been established in Ethiopia. Our first knowledge of it is at this moment, when the Ethiopian king Pankhi already held the Thebais. The energetic prince of Sais, Tefnakht, followed by most of the princes of the Delta, subdued most of Middle Egypt, and by uniting these forces threatened the Ethiopian border. Heracleopolis Magna, however, with its petty king Peltuauabasti, held out against Tefnakht, and Pankhi coming to its aid not only drove Tefnakht out of Middle Egypt, but also captured Memphis and received the submission of the princes and chiefs; in all these included four "kings" and fourteen other chiefs. According to Diodorus the Ethiopian state was theocratic, ruled through the king by the priests of Ammon. The account is probably exaggerated; but even in Pankhi's record the piety of the king, especially towards Ammon, is very marked.

The XXVth Dynasty consisted of a single Saite king named Bocchoris (Bekerrini), son of Tefnakhtus, apparently the above Tefnakht. Another Ethiopian invader, Shabako (Sabacoon), is said to have burnt Bocchoris alive. The Ethiopian rule of the XXVth Dynasty was now firmly established, and the resources of the two countries together might have been employed in conquest in Syria and Phoenicia; but at this very time the Assyrian empire, risen to the highest pitch of military greatness, began to menace Egypt. The pharaohs could not afford to support the Syriacs in their fight for freedom against Sargon and Sennacherib. Shabako was followed by Shebitku and Shebitu by Tirhaka.
EGYPT

(Tahra, Taracos). Tirhaka was energetic in opposing the Assyrian advance, but in 670 B.C. Esarhaddon defeated his army on the border of Egypt, captured Memphis with the royal harem and took great spoil. The Egyptian resistance to the Assyrian advance and perhaps because the country politically at least there must have been a strong party against the Ethiopian rule. Tirhaka laboured to propitiate the north country, and probably rendered the Ethiopian rule acceptable throughout Egypt. Notwithstanding, the Assyrian king entrusted the government and collection of tribute to the native chiefs; twenty princes in all are enumerated in the records, including one Assyrian to hold the key of Egypt at Pelusium. Scarcely had Esarhaddon withdrawn before Tirhaka returned from his refuge in the south and the Assyrian garrisons were massacred. Esarhaddon promptly prepared a second expedition, but died on the way to Egypt in 668 B.C.; his son Assur-bani-pal sent it forward, routed Tirhaka and reinstated the governors. At the head of these was Necho (Niku), king of Sais and Memphis, father of Psammetichus, the founder of the XXVIth Dynasty. We next hear that correspondence with Tirhaka was intercepted, and that Necho, together with Pekrud of Psamtik (at the entrance to the Wadi Tumilat), and the Assyrian governor of Pelusium, was taken to Nineveh in chains to answer the charge of treason. Whatever may have occurred, it was deemed politic to send Necho back loaded with honours and surrounded by a retinue of Assyrian officials. Upper Egypt, however, was loyal to Tirhaka, and even at Memphis the burial of an Apis bull was dated by the priests as in his reign. Immediately afterwards he died. His nephew Tandameia, received by the Upper country with acclamations, besieged and captured Memphis, Necho being probably slain in the encounter. But in 661 (?) Assur-bani-pal drove the Egyptian out of Lower Egypt, pursued him up the Nile and sacked Thebes. This was the last and most tremendous visitation of the Assyrian scourge. Psammetichus (Psammetik), 664–610 B.C., the son of Necho, succeeded his father as a vassal of Assyria in his possessions of Memphis and Sais, allied himself with Gyges, king of Lydia, and aided by Ionian and Carian mercenaries, extended and consolidated his power. By the ninth year of his reign he was in full possession of Thebes. Assurbanipal's energy throughout this crisis were entirely occupied with revolts nearer home, in Babylon, Elam and Arabia. The Assyrian armies again triumphed everywhere, but at the cost of complete extermination. Under the firm and wise rule of Psammetichus, Egypt recovered its prosperity after the terrible losses inflicted by internal wars and the decade of Assyrian invasion. The revenue went up by leaps and bounds. Psammetichus guarded the frontiers of Egypt with three strong garrisons, placing the Ionian and Carian mercenaries especially at the Pelusiac Daphnai in the N.E., from which quarter the most formidable enemy was likely to appear. The Assyrians did not move against him, but a great Scythian horde, destroying all before it in its southward advance, is said by Herodotus to have been turned back by presents and entreaties. Diplomacy backed up by vigorous preparations may have deterred the Scythians from the dangerous enterprise of crossing the desert to Egypt. Before his death Psammetichus had advanced into southern Palestine and captured Azotus.

When Psammetichus began to reign the situation of Egypt was very different from what it had been under the Empire. The development of trade in the Mediterranean and contact with new peoples and new civilizations in peace and war had given birth to new ideas among the Egyptians and at the same time to a loss of confidence in their own powers. The Theban supremacy was gone and the Delta was now the wealthy and progressive part of Egypt; piety increased amongst the masses, unenterprising and unwarlike, but proud of their illustrious antiquity. Thebes and Ammon and the traditions of the Empire favoured too much now of the Egyptian; the priests of the Memphite and Deltaic dynasty thereupon turned deliberately for their models to the times of the ancient supremacy of Memphis, and the sculptures and texts on tomb and temple had to conform as closely as possible to those of the Old Kingdom. In other than religious matters, however, the Egyptians were not unprogressive; and perhaps because the new dynasty was undoubtedly strenuous as it was a self-appointed one. To enumerate a few examples of this are already definitively known: we find that the forms of legal and business documents became more precise; the mechanical arts of casting in bronze on a core and of moulding figures and pottery were brought to the highest pitch of excellence; and portraiture in the round on its highest plane was better than ever before and admirably lifelike, revealing careful study of the external anatomy of the individual. Psammetichus died in the thirty-fifth year of his reign and was succeeded by his son Necho, 610–594 B.C. Taking advantage of the helpless state of the Assyrians, whose capital was assailed by the Medes and the Babylonians, the new Pharaoh prepared an expedition to recover the ancient possessions of the Empire in Syria. Josiah alone, faithful to the king of Assyria, opposed him with a feeble force at Megiddo and was easily overcome and slain. Necho went forward to the Euphrates, put the land to tribute, and, in the case of Judah at any rate, filled the throne with his own nominee (see JERUSALEM). The fall of Nineveh and the division of the spoil gave to Nabopolassar, king of Babylon, the inheritance of the Assyrians in the west, and he at once despatched his son Nebuchadrezzar to fight Necho. The Babylonian and Egyptian forces met at Carchemish (605), and the rout of the latter was so complete that Necho relinquished Syria and might have lost Egypt as well had not the death of Nabopolassar recalled the victor to Babylon. Herodotus relates that in Necho's reign a Phoenician ship despatched from Egypt actually circumnavigated Africa, and the attempt was made to complete a canal through the Wadi Tumilat, which connected the Mediterranean and Red Seas by way of the Lower Egyptian Nile. (See EGYPT.) The next king, Psammetichus II, 504–489 B.C., according to one account made an expedition to Syria or Phoenicia, and apparently sent a mercenary force into Ethiopia as far as Abu Simbel. Pharaoh Hophran (Apries), 585–570 B.C., fomented rebellion against the Babylonian suzerainty in Judah, but accomplished little there. Herodotus, however, describes his reign as exceedingly prosperous. The mercenary troops at Elephanta mutinied and attempted to desert to Egypt, but were brought back and punished. Later, however, a disastrous expedition sent to aid the Libyans against the Greek colony of Cyrene roused the suspicion and anger of the native nsophy at favours shown to the mercenaries, who consequently took part in it. Amasis (Ahmose) II. was chosen king by the former (570–525 B.C.), and his swarm of adherents overcame the Greek troops in Apries' pay (see AMASIS). None the less Amasis employed Greeks in numbers, and cultivated the friendship of their tyrants. His rule was confined to Egypt (and perhaps Cyprus), but Egypt itself was very prosperous. At the beginning of his long reign of forty-four years he was threatened by Nebuchadrezzar; later he joined the league against Cyrus and saw with alarm the fall of his old enemy. A few months after his death, 525 B.C., the invading host of the Persians led by Cambyses reached Egypt and deposed his son Psammetichus III.

Cambyses at first conciliated the Egyptians and respected their religion; but, perhaps after the failure of his expedition into Ethiopia, he entirely changed his policy, and his memory was generally execrated. He left Egypt so completely crushed that the subsequent usurpation of the Persian throne was marked by no revolt in that quarter. Darius, 521–486 B.C., proved himself a beneficent ruler, and in a visit to Egypt displayed his consideration for the religion of the country. In the Great Oasis he built a temple to Ammon. The annual tribute imposed on the satrapy of Egypt and Cyrene was heavy, but it was probably raised with ease. The canal from the Nile to the Red Sea was completed or repaired, and commerce flourished. Documents dated in the thirty-fourth and thirty-fifth years of Darius are not uncommon, but apparently at the very end of his reign,
some years after the disaster of Marathon, Egypt was induced to rebel. Xerxes, 486–467 B.C., who put down the revolt with severity, and his successor Artaxerxes, 465–425 B.C. like Cambyses, were hateful to the Egyptians. The disorders which marked the accession of Artaxerxes gave Egypt another opportunity to rebel. Their leaders were Inaros the Libyan of Marea and the Egyptian Amyrtaeus. Aided by an Athenian force, Inaros slew the satrap Achaemenes at the battle of Paeprim and destroyed his army; but the garrison of Memphis held out, and a fresh host from Persia raised the siege and in turn besieged the Greek and Egyptian forces on the island of Paeprim. At last, after two years, having diverted the river from its channel, they captured and burnt the Athenian ships and quickly ended the rebellion. The reigns of Xerxes II. and Darius II. are marked by no recorded incident in Egypt until a successful revolt about 405 B.C. interrupted the Persian domination.

Monuments of the Persian rule in Egypt are exceedingly scanty. The inscriptions of Pteleuaneit, priest of Neith at Sais, and from his position the native authority who was most likely to be consulted by Cambyses and Darius, tells of his relations with these two kings. For the following reigns Egyptian documents hardly exist, but some papyri written in Aramaic have been found at Elephantine and at Memphis. Those from the former locality show that a colony of Jews with a temple dedicated to Yahweh (Jehovah) had established themselves at that garrison and trading post (see Assuan). Herodotus visited Egypt, and his account of Artaxerxes the Great, 465–425 B.C. This king, the first of the line of Smerdis, founded at Memphis, partly founded on Hecataeus, who had been there about fifty years earlier, is the chief source of information for the history of the Saite kings and for the manners of the times, but his statements prove to be far from correct when they can be checked by the scanty native evidence.

Amyrtaeus (Amnertaeis) of Sais, perhaps a son of Pausiris and grandson of the earlier Amyrtaeus, revolted from Darius II. c. 405 B.C. Egypt regained its independence about sixty years. The next king Neferefre (Nepherites I.) was a Mendesian and founded the XXIXth Dynasty. After Hakor and Neferefre II. the sovereignty passed to Dynasty XXX., the last native Egyptian line. Monuments of all these kings are known, and art flourished particularly under the Mendesian kings Nektahtherek (Nectanebes or Nectanebo I.) and Nektnebek (Nectanebo II.). The former came to the throne when a Persian invasion was imminent, 378 B.C. Hakor had already formed a powerful army, largely composed of Greek mercenaries. This army Nektahtherek entrusted to the Athenian Chabrias. The Persians, however, succeeded in causing his recall and in gaining the services of his fellow-countryman Iphikrates. The invading army consisted of 200,000 barbarians under Pharnabazus and 20,000 Greeks under Iphikrates. After the Egyptians had experienced a reverse, Iphikrates counselled an immediate advance on Memphis. His advice was not followed by Pharnabazus; the Egyptian king collected his forces and won a pitched battle near Mendes. Pharnabazus retreated and Egypt was free.

Nektahtherek was succeeded by Tachos or Teos, whose short reign was occupied by a war with Persia, in which the king of Egypt secured the services of a body of Greek mercenaries under the Spartan king Agesilaus and a fleet under the Athenian general Chabrias. He entered Phoenicia with every prospect of success, but having offended Agesilaus he was dethroned in a military revolt which gave the crown to Nektnebek or Nectanebo II., the last native king of Egypt. At this moment a revolt broke out. The prince of Mendes almost succeeded in overthrowing the new king. Agesilaus defeated the rival pretender and left Nektnebek established on the throne. But the opportunity of a decisive blow against Persia was lost. The new king, Artaxerxes III. Ochus, determined to reduce Egypt. A first expedition was defeated by the Greek mercenaries of Nektnebek, but a second, commanded by Ochus himself, subdued Egypt with no further resistance than that of the Greek garrison of Pelusium. Nektnebek, instead of endeavouring to relieve them, retreated to Memphis and fled thence to Ethiopia, 340 (? B.C.)

Thus miserably fell the monarchy of the Pharaohs, after an unexampled duration of 3000 years, or as some think far longer. More than 2000 years have since passed, and though Egypt has from time to time been independent, not one native prince has sat on the throne of the Pharaohs. "There shall be no more a prince of the land of Egypt" (Ezek. xxvi. 13) was prophesied in the days of Apries as the final state of the land.

Ochus treated his conquest barbarously. From this brief re-establishment of Persian dominion (counted by Manetho as Dynasty XXXX.), no document survives except one papyrus that appears to be dated in the reign of Darius III.

The Conquest by Alexander.—When, in 332 B.C., after the battle of Issus, Alexander entered Egypt, he was welcomed as a liberator. The Persian conqueror did not trouble to oppose him, and he nowhere experienced even the show of resistance. He visited Memphis, founded Alexandria, and went on pilgrimage to the oracle of Ammon (Oasis of Siwa). The god declared him to be his son, renewing thus an old Egyptian con vention or belief; Olympias was supposed to have been in converse with Ammon, even as the mothers of Hateshepsut and Amenophis III. are represented in the inscriptions of the Theban temples as having received the divine essence. At this council of his career the treasure and tribute of Egypt were of great importance to the Macedonian conqueror. He conciliated the inhabitants by the respect which he showed for their religion; he organized the government of the natives under two officers, who must have been already known to them (of these Petris, an Egyptian, soon resigned his share into the charge of his colleague Doloasip, who bears a Persian name.). But Alexander designed his Greek foundation of Alexandria to be the capital, and entrusted the taxation of Egypt and the control of its army and navy to Greeks. Early in 332 B.C. he was ready to depart, and led his forces away to Phoenicia. A granite gateway to the temple of Khnum at Elephantine bears his name in hieroglyphic and demotic documents are found dated in his reign.

The Ptolemaic Period.—On the division of Alexander's dominions in 323 B.C., Egypt fell to Ptolemy the son of Lagus, the founder of the Ptolemaic dynasty (see PTOLEMAES). Under these rulers the rich kingdom was heavily taxed to supply the sinews of war and to support every kind of lavish expenditure. Officials, and the higher ones were nearly all Greeks, were legion, but the whole system was so judiciously worked that there was little discontent amongst the patient peasantry. During the reign of Philadephus the land gained from the bed of the lake of Moeris was assigned to veteran soldiers; the great armies of the Ptolemies were rewarded or supported by grants of farm lands, and men of Macedonian, Greek and Hellenistic extraction were planted in colonies and garrisons or settled themselves in the villages throughout the country. Upper Egypt, farthest from the centre of government, was probably least affected by the new influences, though the first Ptolemy established the Greek colony of Ptolemia to be its capital. Intermarriages, however, gradually had their effect; after the revolt of the natives in the reign of Ptolemy V., we find the Greek and Egyptian elements Chilean government. Ptolemy I. had established the cult of the Memphite Serapis in a Greco Egyptian form, affording a common ground for native and Hellenistic worshippers. The greater number of the temples to the native deities in Upper Egypt and in Nubia (to 50 m. south
of the Cataarct, within the Dodecachosnoites) were built under the Ptolemies. No serious effort was made to extend the Ptolemaic rule into Ethiopia, and Ergamein, the Hellenizing king of Ethiopia, was evidently in alliance with Philopator; in the next reign two native kings, probably supported by Ethiopia, reigned in succession at Thebes. That famous city lost all except its religious importance under the Ptolemies; after the "destruction" or dismantling by Lathyros it formed only a series of villages. The population of Egypt in the time of Ptolemy I. is compared by Diodorus, who makes it that it was greater than it ever was before; at the end of the dynasty, in his own day, it was not much less though somewhat diminished. Civil wars and revolts must have greatly injured both Upper and Lower Egypt. It is remarkable that, while the building and decoration of temples continued in the reigns of Ptolemy Auletes and the later Ptolemies and Cleopatra, papyri of those times whether Greek or Egyptian are scarcely to be found.

Pescennius Niger, who commanded the forces in Egypt, was proclaimed emperor on the death of Pertinax (A.D. 193). Severus overthrew his rival (A.D. 194) and, the revolt having been a military one, did not punish the province; in 202 he gave a constitution to Alexandria and the nome capitals. In his reign the Christians of Egypt suffered the first of their many persecutions. When Christianity was planted in the country we do not know, but it must very early have gained adherents among the settled Jews of Alexandria, whose school of thought was in some respects ready to receive it. From them it rapidly passed to the Greeks. Ultimately the new religion spread to the Egyptians; their own creed was worn out, and they found in Christianity a doctrine of the future life for which their old belief had made them not unready; while the social teaching of Christianity came with special fitness to a subject race. The history of the Coptic Version has yet to be written. It presents some features of great antiquity, and, unlike all others, has the truly popular character of being written in the three dialects of the language. Side by side there grew up an Alexandrian church, philosophic, disputative, ambitious, the very centre of Christian learning, and an Egyptian church, ascetic, contemplative, mystical. The two at length influenced one another; still we can generally trace the philosophic teachers to a Greek origin, the mystics to an Egyptian.

Caracalla, in revenge for an affront, massacred all the men carrying the title of Alexander in Alexandria. This was granting 6,000 Roman citizenship to all Egyptians in common with the other provincials was only to exhort more taxes. Under Decius, A.D. 250, the Christians again suffered from persecution. When the empire broke up in the weak reign of Gallienus, the prefect Aurelianus, who took the surname Alexander or Alexandrinus, was made emperor by the troops at Alexandria, but was conquered by the forces of Gallienus. In his brief reign of only a few months he had driven back an invasion of the Blemmyes. This eastern tribe, issuing from the Blemmyes, was long to be the terror of Upper Egypt. Zenobia, queen of Palmyra, after an unsuccessful invasion, on a second attempt conquered Egypt, which she added to her empire, but lost it when Aurelian made war upon her (A.D. 272). The province was, however, unsettled, and the conquest of Palmyra was followed in the same year by the suppression of a revolt in Egypt (A.D. 273). Probus, who had governed Egypt for Aurelian and Tacitus, was subsequently chosen by the troops to succeed Tacitus, and was the first governor of this province who obtained the whole of the empire. He expelled the Blemmyes, who were dominating the whole of the Thebaid. Diocletian invited the Nobatae to settle in the Dodecaschoenus as a barrier against their incursions, and subsidized both Blemmyes and Nobatae. The country, however, was still disturbed, and in A.D. 290 a formidable revolt broke out, led by Achilles, who as emperor took the name Domitianus. Diocletian, finding his troops unable to determine the struggle, came to Egypt, captured Alexandria and put his rival to death (296). He then reorganized the whole province, and the well known "Pompey's Pillar" was set up by the grateful and repentant Alexandrians to commemorate his gift to them as part of the corn tribute.

The Coptic era of Diocletian or of the Martyrs dates from the accession of Diocletian (A.D. 284). The edict of A.D. 303 against the Christians, and those which succeeded it, were rigorously carried out in Egypt, where Paganism was still strong and face to face with a strong and united church. Galerius, who succeeded Diocletian in the government of the East, implacably pursued his policy, and this great persecution did not end until the persecutor, perishing, it is said, of the dire malady of Herod and Philip II. of Spain, sent out an edict of toleration (A.D. 311).

By the edict of Milan (A.D. 313), Constantine, with the agreement of his colleague Licinius, acknowledged Christianity as having at least equal rights with the religions, and when he gained sole power he wrote to all his subjects advising them, like him, to become Christians (A.D. 324). The Egyptian Church, hitherto free from schism, was now divided by a fierce controversy,
in which we see two Greek parties, rather than a Greek and an Egyptian, in conflict. The council of Nicaea was called together (A.D. 325) to determine between the Orthodox and the party of the Alexandrian presbyter Arius. At that council the native Egyptian bishops were chiefly remarkable for their manly protest against enforcing celibacy on the clergy. The most conspicuous controversialist on the Orthodox side was the young Alexandrian deacon Athanasius, who returned home to be made archbishop of Alexandria (A.D. 346). After being four times exiled by the Arians, and once by the emperor Julian, he died, A.D. 373, at the moment when an Arian persecution began. So large a proportion of the population had taken religious vows that under Valens it became necessary to abolish the privilege of monks which exempted them from military service. The reign of Theodosius I. witnessed the overthrow of Arianism, and this was followed by the suppression of Paganism, against which a final edict was promulgated A.D. 390. In Egypt, the year before, the temple of Serapis at Alexandria had been captured after much bloodshed by the Christian mob and turned into a church. Generally the Coptic Christians were content to build their churches within the ancient temples, plastering over or effacing the sculptures which were nearest to the ground and in the way of the worshippers. They do not seem to have been very zealous in the work of destruction; the native religion was already dead and they had no fear of it. The prosperity of the church was the sign of its decay, and before long the final exodus and retirement were in evidence. Cyril, the patriarch of Alexandria (A.D. 415), expelled the Jews from the capital with the aid of the mob, and by the murder of the beautiful philosopher Hypatia marked the lowest depth to which ignorant fanaticism could descend. A schism now produced lengthened civil war and alienated Egypt from the empire. The distinction between religion and politics seemed to be lost, and the government grew weaker and weaker. The system of local government by citizens that had now entirely disappeared. Offices, with new Byzantine names, were now almost hereditary in the wealthy land-owning families. The Greek rulers of the Orthodox faith were unable to protect the tillers of the soil, and these, being of the Monophysite persuasion and having their own church and patriarchate, hated the Orthodox patriarch (who from the time of Justinian onwards was identical with the prefect) and all his following. Towards the middle of the 5th century, the Blemmyes, quiet since the reign of Diocletian, recommenced their incursions, and were even joined in them by the Nubatae. These tribes were twice brought to account severely for their misdoings, but not effectually checked. It was in these circumstances that Egypt fell without a conflict when attacked by Chosroes (A.D. 616). After ten years of Persian dominion the success of Heraclius restored Egypt to the empire, and for a time it again received a Greek governor. The Monophysites, who had taken advantage of the Persian occupation, were persecuted and their patriarch expelled. The Arab conquest was welcomed by the native Christians, but with it they ceased to be the Egyptian nation. Their language is still used in their churches, but it is no longer spoken, and its literature, which is wholly ecclesiastical, has been long unproductive. The decline of Egypt was due to the purely military government of the Romans, and their subsequent alliance with the Greek party of Alexandria, which never represented the country. Under weak emperors, the rest of Egypt was exposed to the inroads of savages, and left to fall into a condition of barbarism. Ecclesiastical disputes tended to alienate both the native population and the Alexandrians. Thus at last the country was merely held by armed force, and the authority of the governor was little recognized beyond the capital, except where garrisons were stationed. There was no military spirit in a population unused to arms, nor any disinclination to be relieved from an arbitrary and persecuting rule. Thus the Moslem conquest was easy.

2. **Mohammedan Period.**

(1) Moslem Conquest of Egypt.—In accordance with the scheme of universal conquest conceived by the founder of Islam, an army of some 4000 men was towards the end of the year A.D. 639 sent against Egypt under the command of ‘Amr (see ‘AMR-IBN-EL-ASS), by the second caliph, Oman I., who had some doubt as to the expediency of the enterprise. The commander marched from Syria through El-Arish, easily took Farama or Pelusium, and thence proceeded to Bilbeis, where he was delayed for a month; having captured this place, he proceeded to a point on the Nile called Umm Dunain, the siege of which also occasioned him some difficulty. After taking it, he crossed the Nile to the Fayum. On the 6th of June of the following year (640) a second army of about 10,000 men, under the command of Abu ‘Amir and Abu ‘Ubaidah (On). ‘Amr recrossed the river and joined it, but presently was confronted by a Roman army, which he defeated at the battle of Helilopolis (July 640); this victory was followed by the siege of Babylon, which after some futile attempts at negotiation was taken partly by storm and partly by capitulation on Good Friday, the 6th of April 641. ‘Amr next proceeded in the direction of Alexandria, which was surrendered to him by a treaty signed on the 8th of November 641, under which it was to be occupied by the Moslems on the 29th of September of the following year. The interval was spent by him in founding the city Fustat (Fustát), near the modern Cairo, and called after the camp (Fossatum) occupied by him while besieging Babylon; and in reducing those coast towns that still offered resistance. The Thebaid seems to have surrendered with scarcely any opposition. The ease with which this valuable province was wrested from the Roman emperors appears to have been due to the treachery of the governor of Egypt, Cyrus, patriarch of Alexandria, and the incompetence of the generals of the Roman forces. The former, called by the Arabs Mukauks (Muququa) from his Coptic name Pkauchios, had for ten years before the arrival of ‘Amr maintained a fierce persecution of the Jacobite sect, to which the bulk of the Copts belonged. During the siege of Babylon he had been recalled and exiled, but after the death of Heraclius he had been reinstated as patriarch by Heraclonas, and had been welcomed back to Alexandria with general rejoicing in September 641. Since Alexandria could neither have been stormed nor starved out by the Arabs, his motives for surrendering it, and with it the whole of Egypt, have been variously interpreted, some supposing him to have been secretly a convert to Islam. The notion that the Arab invaders were welcomed and assisted by the Copts, driven to desperation by the persecution of Cyrus, appears to be refuted by the fact that the invaders treated both Copts and Romans with the same ruthlessness; but the dissensions which prevailed in the Christian communities, leading to riots and even civil war in Alexandria and elsewhere, probably weakened resistance to the common enemy. An attempt was made in the year 645 with a force under Manuel, commander of the Imperial forces, to regain Alexandria for the Byzantine empire; the city was surprised, and held till the summer of 646, when it was again stormed by ‘Amr. In 645 a fleet was equipped by Constans with a view to an invasion, but it was repulsed, and partly destroyed by storm. From that time no serious effort was made by the Eastern Empire to regain possession of the country. And it would appear that at the time of the attempt by Manuel the Arabs were actually assisted by the
Copts, who at the first had found the Moslem lighter than the Roman yoke.

A question often debated by Arabic authors is whether Egypt was taken by storm or capitulation, but, so far as the transfer-ence of the country was accomplished by the first taking of Alexandria, there seems no doubt that the latter. The terms in correct were those on which conquered communities were ordinarily taken under Moslem protection. In return for a tribute of money (jizya) and food for the troops of occupation (darbati-al-fa‘am), the Christian inhabitants of Egypt were to be excused military service, and to be left free in the observance of their religion and the administration of their affairs.

From 639 to 668 Egypt was a province of the Eastern Caliphate, and was ruled by governors sent from the cities which at different times ranked as capitals. Like other provinces of the later Abbasid Caliphate its rulers were, during this period, able to establish quasi-independent dynasties, such being those of the Tulunids who ruled from 868 to 905, and the Ikhshids from 935-969. In 969 the country was conquered by Jauhar for the Fatimite caliph Mo‘izz, who transferred his capital from Madīdī (g.r.) in the Maghrib to Cairo. This dynasty lasted till 1062. During its reign Egypt was again embodied in the Abbasid empire by Salādīn, who, however, was himself the founder of a quasi-independent dynasty called the Ayyubites or Ayyubids, which lasted till 1260. The Ayyubites were followed by the Mameluke dynasties, usually classified as Bahris from 1253-1328, and Burjis from 1383-1517; these sovereigns were nominally under the suzerainty of Abbasid caliphs, who were in reality instruments of the Mameluke sultans, and resided at Cairo. In 1517 Egypt became part of the empire and was governed by pashas sent from Constantinople, whose influence about 1707 gave way to that of officials chosen from the Mamelukes who bore the title Sheik al-balad. After the episode of the French occupation, government by pashas was restored; Mehemet Ali (appointed pasha in 1805) obtained from the Porte in 1841 the right to bequeath the sovereignty to his descendants, one of whom, Ismail Paşa, received the title Khedive, which is still held by Mehemet Ali's descendants.

(a) The following is a list of the governors of Egypt in these successive periods:

**Twelvew House**

Ahmad b. Tūlūn, 254-270 (868-884).
Khomūrda b. Ahmad, 270-282 (884-906).
Shahāb b. Ahmad, 292 (905).
Mahmūd b. ‘Abbād al-Khalajī, 292-293 (905-906).
Dhah b. Rāmi, 303-307 (915-920).
Takī b. Ahmad, 307-309 (919-921).
Abd ʿAbbās Mahmūd b. ʿAbd al-Malik, 309 (921).
Zahir [Saf of al-din Khoshkadami], 865-872 (1416-1457).
Zahir [Saf al-din Yelbait or Bilbait], 872 (1467).
Zahir [Timurbeghali], 872-873 (1467-1468).
Ashraf [Saf al-din Kair Bey], 873-901 (1468-1495).
Nasir [Mahmoud], 901-903 (1495-1498).
Zahir [Kanshu], 904-905 (1498-1499).
Ashraf [Janjali or Jan Bela], 905-906 (1499-1500).
Adil [Tumanbey], 901-903 (1500-1501).
Ashraf [Kanshu Ghiuri], 906-922 (1501-1516).
Ashraf [Tumanbey], 922 (1516-1517).

(f) Turkish Governors after the Ottoman Conquest.
Khair Bey, 923 (1517).
Mustafa Pasha, 926 (1520).
Ibrahim, 929 (1524).
Qasim, 930 (1524).
Ibrahim, 931 (1525).
Suleiman, 937 (1527).
Dawud, 943 (1538).
Ali, 950 (1549).
Ahmed, 953 (1554).

previously restricted to Lower Egypt; Upper Egypt, which was
divided into three provinces, being assigned to Abdallah b. Sa'd,
on condition that he pay as much as 100,000 dinars to the government of
Egypt also, 'Amr being recalled, owing to his unwillingness to
extend from his subjects as much money as would satisfy the
caliph. In the troubles which overshadowed the Islamic empire with
the accession of Othman, Egypt was greatly involved, and it
had to be reconquered from the adherents of Ali for Moawiya
(Moawiya) by 'Amr, who in a.D. 38 was rewarded for his ser-
vice by being reinstated as governor, with the right to appro-
priate the revenues instead of sending it as tribute to the
metropolis. In the confusion which followed on the death of
the Omayyad caliph Yazid the Egyptian Moslems declared
themselves for Abdallah b. Zobair, but their leader was defeated
in a battle near Ain Shams (December 684) by Merwan b. Hakam
(Merwan II), who had assumed the Caliphate, and the conqueror's
son Abd al-'Aziz was appointed governor. They also declared
themselves against the usurper Merwan II. In 743, whose lie-
utenant al-Hatharah had to enter Fostat at the head of an army.
In 750 Merwan II himself came to Egypt as a fugitive from
the Abbasids, but found that the bulk of the Moslem population
had already joined with his enemies, and was defeated and slain
in the neighbourhood of Giza in July of the same year. The
Abbasid general, Salih b. Ali, who had won the victory, was then
appointed governor.

During the period that elapsed between the Moslem conquest
and the end of the Omayyad dynasty the nature of the Arab
occupation had changed from what had originally been intended,
the establishment of garrisons, to systematic colonization.
Conversions of Copts to Islam were at first rare, and the old
system of taxation was maintained for the greater part of the first
Islamic century. This was at the rate of a dinar per feddan, of
which the proceeds were used in the first place for the pay of the
troops and their families, with about half the amount in kind
for the rations of the army. The process by which the first of
these contributions was turned into coin is still obscure; it is
clear that the corn when threshed was taken over by certain public
officials who deducted the amount due to the state.

In general the system is well illustrated by the papryri forming
the Schott-Reinhardt collection at Heidelberg (edited by C.H. Becker,
1906), which contain a number of letters on the subject from
Qurrab b. Saiar, governor from a.D. 90 to 96. The old division
of the country into districts (nomoi) is maintained, and to the
inside of these districts demand was made by the governor of Egypt,
while the head of the community, ordinarily a Copt, but in some cases a Moslem, is responsible for compliance with the demand. An official called "receiver
(gabbad)" is chosen by the inhabitants of each district to take
charge of the produce till it is delivered into the public magazines,
and receives 5% for his trouble. Some further details are
to be found in documents preserved by the archaeologist
Maqrizi, from which it appears that the sum for which each
district was responsible was distributed over the unit in such
a way that artisans and tradesmen paid at a rate similar to that
which was enforced on those employed in agriculture. It is not
known at what time the practice of having the amount due
settled by the community was altered into that according to
which it was settled by the governor, or at what time the practice of
deducting from the total certain expenses necessary for the
maintenance of the community was abandoned. The researches
of Wellhausen and Becker have made it clear that the difference
which is marked in later Islam between a poll-tax (jizya) and a
land-tax (kharaj) did not at first exist: the papryri of the 1st
century know only of the jizya, which, however, is not a poll-tax
but a land-tax (in the main). The development of the poll-tax
imposed on members of tolerated sects seems to be due to various
causes, chief of them the acquisition of land by Moslems, who
were not at first allowed to possess any; the conversion of Coptic
landowners to Islam, and the enforced sale of the lands of the
1st century of Islam) of the poll-tax on monks. The monarchy
could not afford to lose the land-tax, which it would naturally
thereby lose by the first two of the above occurrences. and we read of
various expedients being tried to avoid this loss. Such were
the Christian community to which the precypte had
an annual land-tax, or they called the government to their
understanding, making prostrate pay as before their conversion, or
compelling them to abandon their lands on conversion. Eventually
the theory spread that all land paid land-tax, whereas members of
terminated sects paid a personal tax also; but during the
evolution of this doctrine the relations between conquerors and
conquered became more and more strained, and from the time
when the control of the finance was separated from the admin-
istration of the country (as it had been in the Sassanid period) the
system of oppression became serious; under the predecessor of Qurrab, 'Abdallah b. 'Abd
al-Malik, the country suffered from famine, and under this ruler it
was unable to recover. Under the finance minister Obaidallah
b. Habbab (720–734) the first government survey by Moslems
was made, followed by a census; but before this time the higher
administrative posts had been largely taken out of the hands of
Copts and filled with Arabs. The resentment of the Copts
finally expressed itself in a revolt, which broke out in the year
725, and was suppressed with difficulty. Two years
after, in order that the Arab element in Egypt might
be strengthened, a colony of North Africans (Qaisites) was sent
for and planted near Bilbeis, reaching the number of 3,000
persons; this immigration also restored the balance between
the two branches of the Arab race, as the first immigrants had
been few and were taken exclusively to the South Arabian stock.
Meanwhile the Arabic language had been steadily gaining ground, and in 706 it was made the official language of the bureaux, though the occasional use of Greek for this purpose is
attested by documents as late as the year 780. Other revolts of
the Copts are recorded for the year 739 and 750, the last
year of Omayyad domination. The outbreaks in all cases are
attributed to increased taxation.

The Abbasid period was marked at its commencement by the
enjoyment of a new capital to the north of Fostat, bearing the
name 'Askur or "camp." Apparently at this time the practice
of farming the taxes began, which naturally led to even greater
extortion than before; and a fresh rising of the Copts is recorded
for the fourth year of Abbasid rule. Governors, as will be
seen from the list, were frequently changed. The three officials
of importance whose nomination is mentioned by the historians
in addition to that of the governor were the commander of the
bodyguard, the minister of finance and the judge. Towards
the beginning of the century there were directed towards Egypt in
fey to a governor was resumed by the caliphal Mamun,
who bestowed this privilege on 'Abdallah b. Tahir, who in 827
was sent to recover Alexandria, which for some ten years had
been held by exiles from Spain. 'Abdallah b. Tahir decided to
reside at Bagdad, sending a deputy to Egypt to govern for him;
and this example was afterwards followed. In 828, when
Mamun's brother Motashim was feudal lord, a violent insurrection
broke out in the south, occasioned, as usual, by excessive taxa-
tion; it was partly quelled in the next year by Motashim,
who marched against the rebels with an army of 4,000 Turks.
The rebellion broke out repeatedly in the following years, and in 831
the Copts joined with the Arabs against the government;
the state of affairs became so serious that the caliphal Mamun himself
visited Egypt, arriving at Fostat in February 834; his general
Afshin fought a decisive battle with the rebels at Bakhartid
in the Haif region, at which the Copts were compelled to
surrender; the males were massacred and the women and children
sold as slaves.

This event finally crushed the Coptic nation, which never
again made head against the Moslems. In the following year
the caliphs Motaishim, who surrounded himself with a foreign body-

guard, withdrew the stipends of the Arab soldiers in Egypt;
this measure caused some of the Arab tribes who had been long
settled in Egypt to revolt, but their resistance was crushed, and
the control of the Ayyubids was thus extended (towards the end
of the 10th century) to that of foreign mercenaries, who, belonging
to one nation or another, held it for most of its subsequent
history. Egypt was given in fief to a Turkish general Ashnás
(Ashnas), who never visited the country, and the rule of individuals of Turkish origin prevailed till the rise of the Fātimid, who for a time interrupted it. The presence of Turks in Egypt is attested.

While the governor was appointed by the feudal lord, the finance minister continued to be appointed by the caliph. On the death of Ashnas in 844 Egypt was given in fief to another Turkish general Itakh, but in 850 this person fell out of favour, and the fief was transferred to Montagir, son of the caliph Motawakkil. In 856 it was transferred from him to the vizier Faţīb b. Khāqān, who for the first time appointed a Turk to be governor. The chief places in the state were soon filled with Turks. The period between the rise of the Abbasids and the quasi-independent dynasties of Egypt was marked by many religious persecution, occasioned by the fanaticism of some of the caliphs, the victims being generally Moslem sectarians. (For Egypt under Motawakkil see Caliphate, § c. par. 10.)

The policy of these caliphs also led to severe measures being taken against any members of the Alid family or adherents of their cause who were to be found in Egypt.

In the year 868 Egypt was given in fief to a Turkish general Bayikbėg, who sent thither as his representative his stepson Abūm b. Tūlūn, the first founder of a quasi-independent dynasty. This personage was himself the son of a Turk who, originally sent as a slave to Bagdad, had risen to high rank in the service of the caliphs. Abūm b. Tūlūn spent some of his early life in Tarus, and on his return distinguished himself by rescuing his caravan, which conveyed a treasure belonging to the caliph, from brigands who attacked it; he afterwards accompanied the caliph Mosta‘in into exile, and displayed some honourable qualities in his treatment of the fallen sovereign. He found a rival in Egypt in the person of Ibn al-Modabbir, the finance minister, who occupied an independent position, and who started the practice of surrounding himself with an army of his own slaves or freedmen; of these Ibn Tūlūn succeeded in depriving the finance minister, and they formed the nucleus of an army by which he eventually secured his own independence. Insurrections by adherents of the Alids gave him the opportunity to display his military skill; and when in 870 his stepfather died, by a stroke of luck the fief was given to his father-in-law, who retained Abūm in the lieutenantcy, and indeed extended his authority to Alexandria, which had till that time been outside it. The enterprise of a usurper in Syria in the year 872 caused the caliph to require the services of Abūm in that country at the head of an army to quell it; and although this army was not actually employed for the purpose, it was not disbanded by Abūm, who on his return founded a fresh city called Kaţā‘ī, “the fiefs,” S.E. of modern Cairo, to house it. On the death of Abūm’s father-in-law in the same year, when Egypt was given in fief to the caliph’s brother Mowaffaq (famous for his defeat of the Zanj), Abūm secured himself in his post by extensive bribery at headquarters; and in the following year the administration of the Syrian frontier was conferred on him as well. By 875 he found himself strong enough to refuse to send tribute to Bagdad, preferring to spend the revenues of Egypt on the maintenance of his army and the erection of great buildings, such as his famous mosque; and though Mowaffaq advanced against him with an army, the project of reducing Abūm to submission had to be abandoned for want of means. In 877 and 878 Abūm advanced into Syria and obtained the submission of the chief revolts, and at Tarus entered into friendly relations with the representatives of the Byzantine emperor. During his absence his son ‘Abdās revolted in Egypt; on the news of his father’s return he fled to Bagdad, whence he endeavoured to conquer the Aghlabite dominions in the Magrib; he was, however, defeated by the Aghlabite ruler, and returned to Bagdad, where he was again defeated by his father’s forces and taken prisoner.

In the relations between Abūm and Mowaffaq again became strained, and the former conceived the bold plan of getting the caliph Mo’tamid into his power, which, however, was frustrated by Mowaffaq’s vigilance; but an open rupture was the result, as Mowaffaq formally deprived Abūm of his lieutenantcy, while Abūm equally formally declared that Mowaffaq had forfeited his succession. A revolt that broke out at Tarsus caused Abūm to traverse Syria once more in 883, but illness compelled him to return, and on the 10th of May 884 he died at his residence in Kaţā‘ī. He was the first to establish the claim of Egypt to govern Syria, and from this time Egypt grew more and more independent of the Eastern caliphate. He appears to have invented the fiction which afterwards was repeatedly employed, by which the money spent on mosque-building was supposed to have been furnished by the caliph, and the buildings were consequently described as “Arab-Moslem.”

He was succeeded by his son Khomārīya, then twenty years of age, who immediately after his accession had to deal with an attempt on the part of the caliph to recover Syria; this attempt failed chiefly through dissensions between the caliph’s officers, but partly through the ability of Khomārīya’s general, who succeeded in winning a battle after his master had run away from the field.

By 886 Mowaffaq found it expedient to grant Khomārīya the possession of Egypt, Syria, and the frontier towns for a period of thirty years, and ere long, owing to the disputes of the provincial governors, Khomārīya found it possible to extend his domain to the Euphrates and even the Tigris. On the death of Mowaffaq in 891 the Egyptian governor was able to renew peaceful relations with the caliphs, and receive fresh confirmation in his possessions for thirty years. The security which he thereby gained gave him the opportunity to indulge in a taste for costly buildings, parks and other luxuries, of which the chroniclers give accounts being on the fabulous. After the marriage of his daughter to the caliph, which was celebrated at enormous expense, an arrangement was made giving the Tūlūnid sovereign the vicereignty of a region extending from Barca on the west to Hit on the east; but tribute, ordinarily to the amount of 300,000 dinars, was to be sent to the metropolis. His realm enjoyed peace till his death in 896, when he fell a victim to some palace intrigue at Damascus.

His son and successor Abū‘l‘Askār Ja‘īsh was fourteen years old at his accession, and being without adequate guidance soon revealed his incompetence, which led to his being murdered after a reign of six months by his troops, who gave his place to his brother Hārūn, who was of about the same age. In the eight years of his government the Tūlūnid empire contracted, owing to the revolts of the deputies which Hārūn was unable to quell, though in 898 he endeavoured to secure a new lease of the sovereignty in Egypt by employing a false caliph and setting up the caliph, involving an increase of tribute. The following years witnessed serious troubles in Syria caused by the Carmathians, which called for the intervention of the caliph, who at last succeeded in defeating these fanatics; the officer Mahommēd b. Solaimān, to whom the victory was due, was then commissioned by the caliph to reconquer Egypt from the Tūlūnids, and after securing the allegiance of the Syrian prefects he invaded Egypt by sea and land at once. Before the arrival of these troops Hārūn had met his death at the hands of an assassin, or else in an affair, and his uncle Shaibān, who was placed on the throne, found himself without the means to collect an army fit to grapple with the invaders.

Fostat was taken by Mahommēd b. Solaimān after very slight resistance, at the beginning of 905, and after the infliction of severe punishment on the inhabitants Egypt was once more put under a deputy, ‘Īsā al-Naushārī, appointed directly by the caliph.

The old régime was not restored without an attempt made by an adherent of the Tūlūnids to reconquer Egypt ostensibly for their benefit, and for a time the caliph’s viceroy had to quit the capital. The vigorous measures of the authorities at Bagdad speedily quelled this rebellion, and the Tūlūnid palace at Kaţā‘ī was then destroyed in order that there might be nothing to remind the Egyptians of the dynasty. In the middle of the year 914 Egypt was invaded for the first time by a Fātimite force from the north, but the caliph al-Mustā‘in was brought off by his Kairawān. The Mahdī’s son succeeded in taking Alexandria, and advancing as far as the Fayūm; but once more the Abbasid
caliph sent a powerful army to assist his viceroy, and the invaders were driven out of the country and pursued as far as Basra; the Fāṭimite caliph, however, continued to maintain active propaganda in Egypt. In 910 Alexandria was again seized by the Māhdi’s son, afterwards the caliph al-Qā’im, and while his forces advanced northward as far as Usnhumun (Eshmunain) he was reinforced by a fleet which arrived at Alexandria. This fleet was destroyed by a far smaller one sent by the Bagdad caliph to Rosetta; but Egypt was not freed from the invaders till the year 921, when reinforcements had been repeatedly sent in to deal with them. The caliph was thus able to turn his forces by these wars for the maintenance of armies and the incompetence of the viceroy brought Egypt at this time into a miserable condition; and the numerous political crises at Bagdad prevented for a time any serious measures being taken to improve it. After a struggle between various pretenders to the vice- royalty, in which some pitched battles were fought, Mohammed b. Ṭughj, son of a Tūlūnid prefect of Damascus, was sent by the caliph to restore order; he had to force his entrance into the country by an engagement with one of the pretenders, Ibn Kaiglugh, in which he was victorious, and entered Fostat in August 935.

Mohammed b. Ṭughj was the founder of the Ikhshīdī dynasty, so called from the title Ikhshīd, conferred on him at his request by the caliph shortly after his appointment to the government of Egypt; it is said to have had the sense of “king” in Fergana, whence this person’s ancestors were said to have come to enter the service of the caliph. He had himself served under the governor of Egypt, Taktim, whose son he displaced, in various capacities, and had afterwards held various governorships in Syria. One of the historians represents his appointment to Egypt as effected by bribery and even forgery. He united in his person the offices of governor and minister of finance, which had been separate since the time of the Tūlūnids. He endeavoured to replenish the treasury not only by extreme economy, but by inflicting fines on a vast scale on persons who had held office under his predecessor and others who had rendered themselves suspect. The disaffected in Egypt kept up communications with the Fāṭimītes, against whom the Ikhshīd collected a vast army, which, however, had first to be employed in resisting an invasion of Egypt threatened by Ibn Rāiq, an adventurer who had seized Syria; after an indecisive engagement at Laqin the Ikhshīd decided to make peace with Ibn Rāiq, undertaking to pay him tribute. The favour afterwards shown to Rāiq at Bagdad shortly threw the Ikhshīd into the arms of the Fāṭimīte caliph, with whom he carried on a friendly correspondence, one letter of which is preserved. He is even said to have given orders to substitute the name of the Fāṭimīte caliph for that of the Abbasid in public prayer, but to have been warned of the unwisdom of this course. In 941, after the death of Ibn Rāiq, the Ikhshīd took the opportunity of invading Syria, which the caliph permitted him to hold with the addition of the sacred cities of Mecca and Medina, which the Tūlūnids had aspired to possess. He is said at this time to have started (in imitation of ʿĀṭīm Ibn Tūlūn) a variety of vexatious enactments similar to those afterwards associated with the name of Hākim, e.g. compelling his soldiers to dye their hair, and adding to their pay for the purpose.

In the year 944 he was summoned to Mesopotamia to assist the caliph, who had been driven from Bagdad by Tūlūn and was in the power of the ʿAbdāl; and he proposed, though unsuccessfully, to take the caliph with him to Egypt. At this time he obtained hereditary rights for his family in the government of that country and Syria. The ʿAbdālīs Saif addaula shortly after this assumed the governorship of Aleppo, and became involved in a struggle with the Ikhshīd, whose general, Kāfūr, he defeated in an engagement between Homs and Hamah (Hamath). In a later battle he was himself defeated by the Ikhshīd, when an arrangement was made permitting Saif addaula to retain most of Syria, while a prefect appointed by the Ikhshīd was put over the remnant. Ibn Tufan, who was now supreme at Bagdad, permitted the Ikhshīd to remain in possession of his vicecy royalty, but shortly after receiving this confirmation he died at Damascus in 946.

The second of this dynasty was the Ikhshīd’s son ʿUnjūr, who had been proclaimed in his father’s time, and began his government under the tutelage of the negro Kāfūr. Syria was immediately overrun by Saif addaula, but he was defeated by Kāfūr in two engagements, and was compelled to recognize the overlordship of the Egyptian viceroy. At the death of ʿUnjūr in 961 his brother Abūl-Ḥasan Ḍalī was made viceroy with the caliph’s consent by Kāfūr, who continued to govern for his predecessor. The land was during this period threatened at once by the Fāṭimītes from the west; the Nubians from the south, and the Carmathians from the east; when the second Ikhshīd died in 965, Kāfūr at first made a pretence of appointing his young son ʿĀṭīm as his successor, but deemed it safer to assume the viceroyalty himself, setting an example which in Mameluke times was often followed. He occupied the post little more than three years, and on his death in 968 the afore-mentioned ʿĀṭīm, called Abūl-Fawwāris, was appointed successor, under the tutelage of a vizier named Ibn Furāt, who had long served under the Ikhshīdīs. The accession of this prince was followed by an incursion of the Carmathians into Syria, before whom the Ikhshīd governor fled into Egypt, where he had for a time to undertake the management of affairs, and arrested Ibn Furāt, who had proved himself incompetent.

The administration of Ibn Furāt was fatal to the Ikhshīdīs and momentous for Egypt, since a Jewish convert, Jacob, son of ʿAbūl-Fawwāris, called from the caliph Moʿizz, was appointed by Ibn Furāt, fled to the Fāṭimīte sovereign, and persuaded him that the time for invading Egypt with a prospect of success had arrived, since there was no one in Fostat capable of organizing a plan of defence, and the dissensions between the Buyyids at Bagdad rendered it improbable that any succour would arrive from that quarter. The Fāṭimīte caliph Moʿizz li-dīn allāh was also in correspondence with other residents in Egypt, where the Ahdī party from the beginning of Abbasid times had always had many supporters; and the danger from the Carmathians rendered the presence of a strong government necessary. The Fāṭimīte general Jauhar (variously represented as of Greek, Slav and Sicilian origin), who enjoyed the complete confidence of the Fāṭimīte sovereign, was placed at the head of an army of 100,000 men—if Oriental numbers are to be trusted—and started from Rakkādah at the beginning of March 969 with the view of seizing Egypt.

Before his arrival the administration of affairs had again been committed to Ibn Furāt, who, on hearing of the threatened invasion, at first proposed to treat with Jauhar for the peaceful surrender of the country; but though at first there was a prospect of this being carried out, the majority of the troops at Fostat preferred to make some resistance, and an advance was made to meet Jauhar in the neighbourhood of Giza. He had little difficulty in defeating the Egyptian army, and on the 6th of July 969 entered Fostat at the head of his forces. The name of Moʿizz was immediately introduced into public prayer, and coins were struck in his name. The Ikhshīdī governor of Damascus, a cousin of Abūl-Fawwāris ʿĀṭīm, endeavoured to save Syria, but was defeated at Ramleh by a general sent by Jauhar and taken prisoner. Thus the Ikhshīdī Dynasty came to an end, and Egypt was transferred from the Eastern to the Western caliphate, of which it furnished the metropolis.

(4) The Fāṭimīte period begins with the taking of Fostat by Jauhar, who immediately began the building of a new city, al-Kāhira or Cairo, to furnish quarters for the army which he had brought. A palace for the caliph and a mosque for the army were immediately constructed, the latter still famous as al-Azhar, and for many centuries the centre of Moslem learning. Almost immediately after the conquest of Egypt, Jauhar found himself engaged in a struggle with the Carmathians (g.r.), whom the Ikhshīdī prefect of Damascus had pacified by a promise of the caliph’s. This promise was not kept by him, and the Fāṭimīte general (Jauhar b. Falāḥ) by whom Damascus was taken, and the Carmathian leader al-Ḥasan b. ʿĀṭīm received
Egypt

In the reign of the second Egyptian Fatimid 'Aziz billah, Jawahir, who appears to have been cashiered by Mo'izz, was again employed at the instance of Jacob b. Killis, who had been raised to the rank of vizier, to deal with the situation in Syria, where a Turkish general Alftakin had gained possession of Damascus, and was raiding the whole country; on the arrival of Jawahir in Syria the Turks called the Carmathians to their aid, and after a campaign of many vicissitudes Jawahir had to return to Egypt to implore the caliph himself to take the field. In August 977 'Aziz met the united forces of Alftakin and his Carmathian ally outside Ramleh in Palestine and inflicted a crushing defeat on them, which was followed by the capture of both the city and the fortress of Lydda and Syria; and the infant, after having been honourably treated by the caliph, thereby incurring the jealousy of Jacob b. Killis, who caused him, it is said, to be poisoned. This vizier had the astuteness to see the necessity of codifying the doctrines of the Fatimites, and himself undertook this task; in the newly-established mosque of el-Azhar he got his master to make provision for a perpetual series of teachers and students of his manual. It would appear, however, that a large amount of toleration was conceded by the first two Egyptian Fatimites to the other sects of Islam, and to other communities. Indeed at one time in 'Aziz's reign the vizierate of Egypt was held by a Christian, Jesus, son of Nestorius, who appointed as his deputy in Syria a Jew, Manasseh b. Abraham. These persons were charged by the Moslems with unduly favouring their co-religionists, and the belief that the Christians of Egypt were in league with the Byzantine emperor, and even burned a fleet which was being built for the Byzantine war, led to some persecution. Aziz attempted without success to enter into friendly relations with the Buyid ruler of Bagdad, 'Adod addaula, who was disposed to favour the 'Alids, but caused the claim of the Fatimites to descend from 'Ali to be publicly refuted. He then tried to gain possession of Aleppo, as the key to Irak, but this was prevented by the intervention of the Byzantines. His North African possessions were maintained and extended by 'Ali, son of Bulukkin, whom Mo'izz had left as his deputy; but the recognition of the Fatimites caliph in this region was little more than nominal.

His successor 'Abd al-Mansur, who reigned under the title al-Hakim bi'amir allah, came to the throne at the age of eleven, being the son of 'Aziz by a Christian mother. He was at first under the tutelage of the Slav Burjwuan, whose policy it was to favour the Turkish element in the army as against the Maghribine, on which the strength of the Fatimites had till then rested; his conduct of affairs was vigorous and successful, and he concluded a peace with the Greek emperor. After a few years' regency he was assassinated at the instance of the young sovereign, who at an early age developed a dislike for control and jealousy of his rights as caliph. He is branded by historians as the Caligula of the East, who took a delight in tormenting his subjects a variety of senseless and capricious regulations, and persecuting different sections of them by cruel and arbitrary measures. It is observable that some of those with which Hakim is credited are also ascribed to Ibn Tulun and the Ikhshid (Mahommed b. Tughj). He is perhaps best remembered by his destruction of the church of the Holy Sepulchre at Jerusalem (1010), a measure which helped to provoke the Crusades, but was only part of a general scheme for converting all Christians and Jews in his dominions to his own opinions by force. A more reputable expedient with the same end in view was the construction of a great library in Cairo, with ample provision for students; this was modelled on a similar institution at Bagdad. It formed part of the great palace of the Fatimites, and was intended to be the centre of their propaganda. At times, however, he ordered the destruction of all Christian churches in Egypt, and the banishment of all who did not adopt Islam. But it is strange that in the midst of these persecutions he continued to employ Christians in high official positions. His system of persecution was not abandoned till in the year of his reign (1020) he thought fit to claim divinity, a doctrine which is perpetuated by the Druses (q.f.), called after one Daraz, who preached the divinity of Hakim at the time; the violent opposition which this aroused among the Moslems probably led him to adopt milder measures towards his other subjects, and those who had been forcibly converted were permitted to return to their former religion and rebuild their places of worship. Whether his disappearance at the beginning of the year 1021 was due to the resentment of his outraged subjects, or, as the historians say, to his sister's fear that he would bequeath the caliphate to a distant relative to the exclusion of his own son, will never be known. In spite of his caprices he appears to have shown competence in the management of external affairs; enterprises of pretenders both at Bagdad and Syria were crushed with promptitude; and his name was at times mentioned in public worship in Aleppo and Mosul.

His son Abul-Hasan 'Ali, who succeeded him with the title al-Zahir li'visa din allah, was sixteen years of age at the time, and for four years his aunt Sitt al-Mulk acted as regent; she appears to have been an astute but utterly unscrupulous woman. After her death the caliph was in the power of various ministers, under whose management of affairs Syria was for a time lost to the Egyptian caliphate, and Egypt itself raided by the Syrian usurpers, of whom one, Sâlih b. Mirâdâ, succeeded in establishing a dynasty at Aleppo, which maintained itself after Syria and Palestine had been recovered for the Fatimites by Anushatkin al-Dizbari at the battle of Ukhwânâ in 1029. His career is said to have been marked by some horrible caprices similar to those of his father. After a reign of nearly sixteen years he died of the plague.

His successor, Abu Tamim Maar'ith, who reigned with the title al-Mostansir, was also an infant at the time of his accession, being little more than seven years of age. The power was largely in the hands of his mother, a negress, who promoted the interests of her kinsmen at court, where indeed in Hakim's time they had been used as a counterpoise to the Maghribine and Turkish elements in the army. In the first years of this reign affairs were administered by the vizier al-Jarjarâ, by whose mismanage ment Aleppo was lost to the Fatimites. At his death in 1044 the chief influence passed into the hands of Abu Sa'd, a Jew, and the former master of the queen-mother, and at the end of
four years he was assassinated at the instance of another Jew (Ṣadāqah, perhaps Zedekiya, b. Joseph al-Falaki), whom he had appointed vizier. During his reign Mo'izz el-Basidi, the 4th ruler of the independent Zahirid dynasty which had ruled in the Maghrib since the migration of the Fātimide Mo'izz to Egypt, definitely abjured his allegiance (1049) and returned to Sunnite principles and submission to the Bagdad caliphate. The Zahirids maintained Mahdia (see Algeria), while other cities of the Maghrib were colonized by Arab tribes sent thereto by the Cairene vizier. This loss was more than compensated by the enrolment of Yemen among the countries which recognized the Fātimide caliphate there. Even the Isfahān, who took the title of 'Alī on leaving Egypt, and proclaimed himself 'Alī-Sulayḥ, while owing to the disputes between the Turkish generals who claimed supremacy at Bagdad, Mostānṣir's name was mentioned in public prayer at that metropolis on the 17th of January 1058, when a Turkish adventurer Basārṣī was for a time in power. The Egyptian court, chiefly owing to the jealousy of the vizier, sent no efficient aid to Basārṣī. After a year Bagdad was retaken by the Seljuk Toghrul Beg, and the Abbasid caliph restored to his rights. In the following years the troubles in Egypt caused by the struggles between the Turkish and negro elements in Mostānṣir's army nearly brought the country into the dominion of the Abbasids. After several battles of various issue the Turkish commander Nāṣir ad-dawla b. Hamdān got possession of Cairo, and at the end of 1058 plundered the caliph's palace; the valuable library which had been begun by Hākim was pillaged, and an accidental fire caused great destruction. The caliph and his family were reduced to destitution, and Nāṣir ad-dawla began negotiations for the caliph's recognition of him as co-caliph in public prayer; he was, however, assassinated before he could carry this out, and his assassin, also a Turk, appointed vizier. Mostānṣir then summoned to his aid Badr al-Jamālī, an Armenian who had displayed competence in various posts which he had held in Syria, and this person early in 1074 arrived in Cairo accompanied by a bodyguard of Armenians; he contrived to massacre the chiefs of the party at the time in possession of power, and with the title Āmir al-Ḫiyara ("the power of the armies") was given by Mostānṣir complete control of affairs. The period of internal disturbances, which had been accompanied by famine and pestilence, had caused usurers to spring up in all parts of Egypt, and Badr was compelled practically to reconquer the country. During this time, however, Syria was over-run by an invader in league with the Seljuk Malik Shah, and Damascus was permanently lost to the Fātimides; other cities were lost to the Arabs. He rebuilt the walls of Cairo, of more durable material than that which he had employed in his own time. He was of medium height, with a short beard, with piercing eyes. He was the first true vizier of Fātimid times; his is the reign which marked the turning point in the Fātimide history. The reign of Mostānṣir is otherwise memorable for the rise of the Assassins (q.v.), who at the first supported the claims of his eldest son Nāṣir to the succession against the youngest Āḥmad, who was favoured by the family of Badr. When Badr died in 1094 his influence was inherited by his son al-Āṣf al-Shāhī and this, at the death of Mostānṣir in the same year, was thrown in favour of Āḥmad, who succeeded to the caliphate with the title al-Musta'sī bīlāh. Mosta'sī's succession was not carried through without an attempt on the part of Nāṣir to obtain his rights, the title which he chose being al-Musta'sī bīlān al-lāhū. For this title he maintained himself in Alexandria, but the energetic measures of his brother soon brought the civil war to an end. The beginning of this reign coincided with the beginning of the Crusades, and al-Āṣf made the fatal mistake of helping the Franks by rescuing Jerusalem from the Otokids, thereby facilitating its conquest by the Franks in 1099. He endeavoured to retrieve his error by himself advancing into Palestine, but he was defeated in the neighbourhood of Ascalon, and compelled to retire to Egypt. Many of the Palestinian possessions of the Fātimides swiftly fell into the hands of the Franks. After a reign of seven years Mosta'sī died and the caliphate was given by al-Āṣf to an infant son, aged five years at the time, who was placed on the throne with the title al-Āmir bi-ikhwām al-lāh, and for twenty years was under the tutelage of al-Āṣf. He made repeated attempts to recover the Syrian and Palestinian cities from the Franks, but with poor success. In 1128 Egypt was invaded by Baldwin L., who burned the gates and the mosques of Farara, and advanced to Tinnis, whence illness compelled him to retreat. In August 1128 al-Āṣf was assassinated in a street of Cairo, it is said, with the connivance of the caliph, who immediately began the plunder of his house, where fabulous treasures were said to be amassed. The vizier's offices were given to one of the caliph's creatures, Mahommed b. Fārik, who took the title of Āmīr al-Musta'sī bīlān al-lāh. He was not more fortunate than that of his predecessor, as he lost Tyre to the Franks, and a fleet equipped by him was defeated by the Venetians. On the 4th of October 1125 he with his followers was seized and imprisoned by order of the Caliph Āḥmad, who was now resolved to govern by himself, with the assistance of only subordinate officials, of whom two were drawn from the Samaritan and Christian communities. The vizier was afterwards crucified with his five brothers. The caliph's personal government appears to have been incompetent, and to have been marked by extortions and other arbitrary measures. He was assassinated in October 1129 by some members of the sect who believed in the claims of Nāṣir, son of Mostānṣir. The succeeding caliph, Abūl-Ma'mūn Abd al-Malik, who took the title al-Ḫāja bīlān al-lāhū, was not the son but the cousin of the deceased caliph, and of ripe age, being about fifty-eight years of age at the time; for fourteen months he was kept in seclusion by the new vizier a son of the Āṣf, whose name and title had been chosen, but the vizier'suates by the factious soldiery, among which several battles took place, ending in the subjection of the caliph for a time to various usurpers, one of these being his own son Ḥasan, who had been provoked to rebel by the caliph nominating a younger brother as his successor. For some months the caliph was under this son's control; but the latter, who aimed at conciliating the people, speedily lost his popularity with the troops, and his father was able to get possession of his person and cause him to be poisoned (beginning of 1135). His son Abūl-Munṣīr Ismā'īl, who was seventeen years old at the time of his father's death, succeeded him with the title al-Ḫāja bīlān al-lāhū. From this reign to the end of the Fātimide period we have the journals of two eminent men, Ụṣmān b. Muniqţī and 'Alī b. Ṣafī. The first is important for the light it casts on the religious characters of the times. The civil divisions of Egypt were notorious at the time. The new regime began by an armed struggle between two commanders for the post of vizier, which in January 1150 was decided in favour of the Amir Ibn Sallār. This vizier was presently assassinated by the direction of his stepson 'Abbās, who was raised to the vizierate in his place. This event was shortly followed by the loss to the Fātimids of Ascalon, the last place in Syria which they held; its loss was attributed to divisions between the parties of which the garrison consisted. Four years later (April 1154) the caliph was murdered by his vizier 'Abbās, according to Ụṣmān, because the caliph had suggested to his favourite, the vizier's son, to murder his father; and this was followed by a massacre of the brothers of Ụṣmān, followed by the raising of his infant son Abūl-Qāsim 'Īsā to the throne. The new caliph, who was not five years old, received the title al-Pīdī bīlān al-lāhū, and was at first in the power of 'Abbās. The women of the palace, however, summoned to their aid Talī 'b. Ruzzik, prefect of Usmanunais, at whose arrival in Cairo the troops deserted 'Abbās, who was compelled to flee into Syria, taking his son and Ụṣmān with him. 'Abbās was killed by the Franks near Ascalon, his son sent in a cage to Cairo where he was executed, while Ụṣmān escaped to Damascus. The infant Talī, who had been permanently incapacitated by the scenes of violence which accompanied his accession, died in 1160. 'Īsā' b. Ruzzik chose to succeed him a grandson of Āmīr, the same year of age, and received the title Āḍād bīlān al-lāhū. 'Īsā', who had complete control of affairs, introduced the
practice of farming the taxes for periods of six months instead of a year, which led to great misery, as the taxes were demanded twice. His death was brought about by the rigour with which the caliph, with the concurrence of the followers of the caliph, organized a plot for his assassination, and he died in September 1160. His son Ruzzik inherited his post and maintained himself in it for more than a year, when another prefect of Upper Egypt, Shāwār b. Mu'ājr, brought a force to Cairo, before which Ruzzik fled, to be shortly afterwards captured and beheaded. Shāwār's entry into Cairo was at the beginning of 1163; after nine months he was compelled to flee before another adventurer, an officer in the army named Dirghām; Shāwār's flight was directed to Damascus, where he was favourably received by the prince Nureddin, who sent with him to Cairo a force of Kurds under Asad al-dīn Shīrgāt. At the same time Egypt was invaded by the Franks, who raised and did much damage on the coast. Dirghām was defeated and killed, but a dispute arose between Shāwār and his Syrian allies for the possession of Egypt. Shāwār, being unable to cope with the Syrians, demanded help of the Frankish king of Jerusalem Amalric (Amurri) Šarāz, who hastened to his aid with a large force, which united with Shāwār's and besieged Shīrgāt in Bilbeis for three months; at the end of this time, owing to the successes of Nureddin in Syria, the Franks granted Shīrgāt a free passage with his troops back to Syria, on condition of Egypt being evacuated (October 1164). Rather more than two years later Shīrgāt persuaded Nureddin to attack the head of his ally in Egypt, which left Syria in January 1167, and, entering Egypt by the land route, crossed the Nile at Iltīb (Atbāh), and encamped at Giza; a Frankish army hastened to Shīrgāt's aid. At the battle of Bābāin (April 11th, 1167) the allies were defeated by the forces commanded by Shīrgāt and his nephew Saladin, who was presently made prefect of Alexandria, which surrendered to Shīrgāt without a struggle. Saladin was soon besieged by the allies in Alexandria; but after seventy-five days the siege was raised, Shīrgāt having made a threatening movement on Cairo, where a Frankish garrison had been admitted by Shāwār. Terms were then made by which both Syrians and Franks were to quit Egypt, though the garrison of Cairo remained; the hostile attitude of the Moslem population to this garrison led to another invasion at the beginning of 1168 by King Amalric, who after taking Bilbeis advanced to Cairo. The caliph appointed the Franks to hold his place in Cairo, while he left to his nephew the regency, for which after a few months he substituted the sovereignty, causing his nephew to be deposed. He reigned under the title Malik al-'Adil Sayf al-dīn. His name was Abū Bakr.

Though the early years of his reign were marked by numerous disasters, famine, pestilence and earthquake, of which the second seems to have been exceedingly serious, he reunited under his sway the whole of the empire which had belonged to his brother, and his generals conquered for him parts of Mesopotamia and Armenia, and in 1215 he possessed Sweden. He followed the plan of dividing his empire between his sons, the eldest Mahommed, called Malik al-Kāmil, being his viceroy in Egypt, while al-Mu'azzam 'Īsā governed Syria, al-Eshraf Mūsā his eastern and al-Malik al-Ashraf Ayyūb his northern possessions. His attitude towards the Franks was at the first peaceful, but later in his reign he was compelled to adopt more strenuous measures. His death occurred at Alkīn (1218), a village near Damascus, while the Franks were besieging Damietta—the first operation of the Fifth Crusade—which was defended by al-Kāmil, to whom his father kept sending reinforcements. The efforts of al-Kāmil after his accession to the independent sovereignty were seriously hindered by the endeavours of an amir named Abū al-Mu'azzam al-Mu'izzī, who came to Egypt to aid his brother in February 1219, and compelled al-Fā'īs to depart for Mosul. After a siege of sixteen and a half months Damietta was taken by the Franks on Tuesday the 6th of November 1219; al-Kāmil thereupon proclaimed the
Jihād, and was joined at his fortified camp, afterwards the site of Manṣūra, by troops from various parts of Egypt, Syria and Mesopotamia, including the forces of his brothers Isā and Muṣṣa. With these allies, and availing himself of the advantages offered by the disaffection of the Ayyūbīs, Salāḥ al-Dīn was able to strike off both the advance and the retreat of the invaders, and on the 31st of August 1221 a peace was concluded, by which the Franks evacuated Egypt.

For some years the dominions of al-ʿAdīl remained divided between his sons: when the affairs of Egypt were settled, al-Kāmil determined to reunite them as before, and to that end brought on the Sixth Crusade. Various cities in Palestine and Syria were yielded to Frederick II., as the price of his help against the son of Muʿazzam isā, who reigned at Damascus with the title of Malik al-Nāṣir. About 1231–32 Kāmil led a confederacy of Ayyūbī princes against the Seljuk Kaikobad into Asia Minor, but his allies mistrusted him and victory rested with Kaikobad (see SALJUGS). Before Kāmil's death he was mentioned in public prayer at Mecca as lord of Mecca (Hejaz), Yemen, Zabīd, Upper and Lower Egypt, Syria and Mesopotamia.

At his death (May 9th, 1238) at Damascus, his son Abū Bakr was the first to succeed with the title Malik al-ʿAdīl Sayf al-dīn; but his elder brother Malik al-Sāliḥ Najm al-dīn Ayyūbī, having got possession of Damascus, immediately started for Egypt, with the view of adding that country to his dominions: meantime his uncle Isāmālī, prince of Hamath, with the prince of Homs, seized Damascus, upon hearing which the troops of Najm al-dīn deserted him at Nablus, when he fell into the hands of Malik al-Nāṣir, prince of Karak, who carried him off to that city and kept him a prisoner there for a time; after which he was released and allowed to return to Nablus. On the 31st of May 1240 the new sultan was arrested at Bibeis by his own amirs, who sent for Najm al-dīn to succeed him; and on the 19th of June of the same year Najm al-dīn entered Cairo as sultan, and imprisoned his brother in the citadel, where he died in 1245. Meanwhile in 1244 Jerusalem had been finally wrested from the Franks. The administration of Najm al-dīn is highly praised by Ibn Khalikān, who lived under it. He made large purchases of slaves (Mamelukes) for his army, and when the inhabitants of Cairo complained of their lawlessness, he built barracks for them on the island of Roda (Raudja), whence they were called Bahri or Nile Mamelukes, which became the name of the first dynasty that originated from them. Much of his time was spent in campaigns in Syria, where the other Ayyūbīs allied themselves against him with the Crusaders, whereas he accepted the services of the Ayyūbīs, eventually succeeding in recovering most of the Syrian cities. His name is commemorated by the town of Sāliḥia, which he built in the year 1246 as a resting-place for his armies on their marches through the desert from Egypt to Palestine. In 1249 he was recalled from the siege of Homs by the news of the invasion of Egypt by Louis IX. (the Seventh Crusade), and in spite of illness he hastened to Usūmum Tāni, in the neighbourhood of Damietta, which he provisioned for a siege. Damietta was taken on the 6th of June 1249, owing to the desertion of his post by the commander Fakhr ud-dīn, and the Bāฏtūr Kīnānāḥ, to whom the defence of the place had been entrusted: fifty-four of their chieftains were afterwards executed by the sultan for this proceeding. On the 22nd of November the sultan died of disease at Manṣūra, but his death was carefully concealed by the amirs Lājin and Aktaī, acting in concert with the Queen Shajar al-durr, till the arrival from Syria of the heir to the throne, Tūrāshād, who was proclaimed some four months later. At the battle of Fārīskūr, 6th of April 1250, the invaders were utterly routed and the French king fell into the hands of the Egyptian sultan. The Egyptian authorities now resolved to rage Damietta, which, however, was rebuilt shortly after. The sultan, who himself had had no share in the victory, advanced after it from Manṣūra to Fārīskūr, where his conduct became menacing to the amirs who had raised him to the throne, and Shajar al-durr; she in revenge organized an attack upon him which was successful, fire, water, and steel contributing to his end.

(6) Period of Bahri Mamelukes.—The dynasties that succeeded the Ayyūbīs till the conquest of Egypt by the Ottomans bore the title Dynasties of the Turks, but are more often called Mameluke dynasties, because the sultans were drawn from the Turco-Mongol tribes of the empire who formed the guard of the caliphate. The first to rule after the fall of Cairo was the son of Salāḥ al-Dīn, the last of the Ayyūbīs, al-Muṣṭafā, who reigned for 118 years, and was succeeded by his son. But the rule of a queen caused scandal to the Moslem world, and Shajar al-durr gave way to this sentiment by marrying Aibek and allowing the title sultan to be conferred on him instead of herself. For policy's sake, however, Aibek nominally associated with himself on the throne a scion of the Ayyūbī house, Malik al-ʿAshraf Muṣṭafā, who died in prison (1252 or 1254). Aibek meanwhile immediately became involved in war with the Ayyūbīs Malik al-Nāṣir, who was in possession of Syria, with whom the caliph induced him after some indecision to make peace: he then successfully quelled a mutiny of Mamelukes, whom he compelled to take refuge with the last Abbasid caliph Mostasim in Bagdad and elsewhere. On the 10th of April 1257 Aibek was murdered by his wife Shajar al-durr, who was indignant at his asking for the hand of another queen: but Aibek's followers immediately avenged his death, placing on the throne his infant son Malik al-ʿAzmūrī, who, however, was almost immediately displaced by his guard Mār Kūṭūz, on the plea that the Mongol danger necessitated the presence of a grown man at the head of affairs. In 1260 the Syrian kingdom of al-Nāṣir was destroyed by Hulaku (Hulagu), the great Mongol chief, founder of the Ilkhān Dynasty (see MONGOLS), who, having finally overthrown the caliph of Bagdad (see CALIPHATE, sect. c. § 37), also despatched a threatening letter to Kūṭūz; but later in the same year Syria was invaded by Kūṭūz, who defeated Hulagu's lieutenant at the battle of 'Ain Jalut (3rd of September 1260), in consequence of which the event the Syrian cities all rose against the Mongols, and the Egyptian sultan became master of the country with the exception of such places as were still held by the Crusaders.

Before Kūṭūz had reigned a year he was murdered at Sāliḥia by his lieutenant Bībars (October 23rd, 1260), who was piqued, it is said, at the governorship of Aleppo being withheld from him. The sultan was succeeded by a person with the title Malik al-Qāhirī, presently altered to al-Zāhirī. He had originally been a slave of Malik al-Sāliḥ, had distinguished himself at the battle after which Louis IX. was captured, and had helped to murder Tūrāshāh. Sultan Bībars, who proved to be one of the most competent of the Bahri Mamelukes, made Egypt the centre of the Moslem world by re-establishing in theory the Abbasid caliphate, which had lapsed through the taking of Bagdad by Hulagu, followed by the execution of the caliph. Bībars recognized the claim of a certain Abūl-Qāsim ʿAḥmed to be the son of Zāhirī, the 33rd Abbasid caliph, and installed him as Commander of the Faithful at Cairo with the title al-Mostasīrī billāh. Mostasīrī then proceeded to confer on Bībars the title sultan, and to address him a homily, explaining his duties. This document is preserved in the MS. life of Bībars, and translated by G. Well. The sultan appears to have contemplated restoring the new caliph to the throne of Bagdad: the force, however, which he sent with him for the purpose of reconquering Irak was quite insufficient for the purpose, and Mostasīrī was defeated and slain. This did not prevent Bībars from maintaining his policy of appointing an Abbasid for the purpose of conferring legitimacy on himself; but he encouraged no further attempts at re-establishing the Abbasid caliphate, and his principle, adopted by successive Abbasid caliphs, was that the Abbasid caliph should not leave Cairo except when accompanying the sultan on an expedition.
The reign of Bibars was spent largely in successful wars against the Crusaders, from whom he took many cities, notably Safad, Caesarea and Antioch; the Armenians, whose territory he repeatedly invaded, burning their capital Sis; and the Seljuks of Asia Minor. He further reduced the I mam's of Assassins, who for the most part were only to a limited extent in Syria as a result of his successes which he nearly came to an end in Persia. He made Nubia tributary, therein extending Moslem arms farther south than they had been extended by any previous sultan. His authority was before his death recognized all over Syria (with the exception of the few cities still in the power of the Franks), over Arabia, with the exception of Yemen, on the Euphrates from Birah to Kerkesia (Circulars) on the Chaboras (Khabur), whilst the amirs of Manzikert, as far as the third of other amirs who had driven off the franks, were tributary to him. His successes were won not only by military and political ability, but also by the most absolute unscrupulousness, neither flagrant perjury nor the basest treachery being disdained. He was the first sultan who acknowledged the equal authority of the four schools of law, and appointed judges belonging to each in Egypt and Syria; he was thus able to get his measures approved by one school when condemned by another.

On the 1st of July 1277 Bibars died, and the events that followed set an example repeatedly followed during the period of the Mamelukes. The sultan's son Malik al-Sa' id ascended the throne; but within little more than two years he was compelled to abdicate in favour of his father-in-law Kalâtn, a Mameluke who had risen high in the former sovereign's service. The accession of Kalâtn was also marked by an attempt on the part of the governor of Damascus to form Syria into an independent kingdom, an attempt frequently imitated on similar occasions. The Syrian forces were defeated at the battle of Jazirah (April 26th, 1280) and Kalâtn resumed possession of the country; but the disaffected Syrians entered into relations with the Mongols, who proceeded to invade Syria, but were finally defeated by Kalâtn on the 30th of October 1281 under the walls of Homs (Emesa).

The conversion to Islam of Nikudar Ahmad, the third of the Ilkhan rulers of Persia, and the consequent troubles in the western Mongol empire, led to a suspension of hostilities between Egypt and the Ilkhans (see PERSIA: History, § B), though the latter did not cease to agitate in Europe for a renewal of the Crusades, with little result. Kalâtn, without pursuing any career of active conquest, did much to consolidate his dominions, and especially to extend Egyptian commerce, for which purpose he started passports enabling merchants to travel with safety through Egypt and Syria as far as Jindia. After the danger from the Mongols had passed, however, Kalâtn directed his energies towards capturing the last places that remained in the hands of the Franks, and proceeded to take Markab, Latakia, and Tripoli (April 26th, 1289). In 1290 he planned an attack on Acre, but died (November 10th) in the middle of all his preparations. Under Kalâtn we first hear of the Burjite Mamelukes, who owe their name to the citadel (Burj) of Cairo, where 37000 of the whole number of 12,000 Mamelukes maintained by this sovereign were quartered. He also set an example frequently followed, of the practice of dismissing all non-Moslems from government posts: this was often done by his successors with the view of conciliating the Moslems, but it was speedily found that the services of the Jewish and Christian clerks were again required. He further founded a hospital for clinical research on a scale formerly unknown.

Kalâtn was followed by his son Khalil (Malik al-Asbrof Salah al-din), who carried out his father's policy of driving the Franks out of Syria and Palestine, and proceeded with the siege of Acre, which he took (May 18th, 1291) after a siege of forty-three days. The capture and destruction of this important place were followed by the capture of Tyre, Sidon, Haifa, Aithit and Beirut, and thus Syria was cleared of the Crusaders. He also planned an expedition against the prince of Lesser Armenia, which was averted by the surrender of Berehes, Marash and Tell Hamdon. The disputes between his favourite, the vizier Ibn al-Sa' ids, and his viceroy Baida, led to his being murdered by the latter (December 12th, 1293), who was proclaimed sultan, but almost immediately fell a victim to the vengeance of the deceased sultan's party, who placed a younger son of Kalâtn, Mehemmed Malik al-Nasir, on the throne. This prince had the singular fortune of reigning three times, twice being dethroned and three times in throne, once in Syria (1294), once in Palestine (1299), and once in Egypt (1307). He was nine years old, and the affairs of the kingdom were undertaken by a cabinet, consisting of a vizier (Alam al-din Sinjar), a viceroy (Kitboga), a war minister (Husam al-din Lajin al-Rum), a prefect of the palace (Rokneddin Bibars Jashengir) and a secretary of state (Rokneddin Bibars Mansuri). This cabinet naturally split into rival camps, in consequence of which Kitboga, himself a Mongol, and the amirs who had done most harm to the sultan, in the battle of Homs, succeeded in ousting his rivals, and presently, with the aid of the surviving assassins of the former sultan, compelling Malik al-Nasir to abdicate in his favour (December 1st, 1294). The usurper was, however, able to maintain himself for two years only, famine and pestilence which prevailed in Egypt and Syria during his reign rendering him unpopular, while his arbitrary treatment of the amirs also gave offence. He was dethroned in 1296, and one of his murderers of the Kalâtn, Husam al-din Lajin, son-in-law of the sultan Bibars and formerly governor of Damascus, installed in his palace (November 26th, 1296). It had become the practice of the Egyptian sultans to bestow all offices of importance on their own freedmen (Mamelukes) to the exclusion of the older amirs, whom they could not trust so well, but who in turn became still more disaffected. Husam al-din fell a victim to the jealousy of the older amirs whom he had incensed by bestowing arbitrary power on his own Mameluke Meniuinmur, and was murdered in the 16th of January 1297. His short reign was marked by some fairly successful incursions into Armenia, and the recovery of the fortresses Marash and Tell Hamdon, which had been retaken by the Armenians. He also instituted a fresh survey and division of land in Egypt and Syria, which occasioned much discontent. After his murder the deposed sultan Malik al-Nasir, who had been living in retirement at Kerak, was recalled by the army and reinstated as sultan in Cairo (February 7th, 1299), though still only fourteen years of age, so that public affairs were administered not by him, but by Salar the vizier, and Bibars Jashengir, prefect of the palace. The 7th Ilkhan, Ghazan Mahmud, took advantage of the disorder in the Mameluke empire to invade Syria in the latter half of 1290, when his forces inflicted a severe defeat on those of the new sultan, and seized several cities, including the capital Damascus, of which he afterwards made his chief centre of operations. In 1292, when a fresh army was collected in Egypt, the Mongols evacuated Damascus and made no attempt to secure their other conquests. The fear of further Mongolian invasion led to the imposition of fresh taxes in both Egypt and Syria, including one of 33% on rents, which occasioned many complaints. The invasion did not take place till 1303, when the battle of Mar al-Saffar (April 20th) the Mongols were defeated. This was the last time that the Ilkhans gave the Egyptian sultans serious trouble; and in the letter written in the sultan's name to the Ilkhan announcing the victory, the former suggested that the caliphate of Bagdad should be restored to the titular Abbasid caliph who had accompanied the Egyptian expedition, a suggestion which does not appear to have led to any actual steps being taken. The fact that the Mongols were in ostensible alliance with Christian princes led to a renewal by the sultan of the ordinances against Jews and Christians which had often been abrogated; in 1302, it was renewed and again fallen into disuse; and some renewal led to missions from various Christian princes requesting milder terms for their co-religionists. The amirs Salar and Bibars having usurped the whole of the sultan's authority, he, after some futile attempts to free himself of them, under the pretext of pilgrimage to Mecca, retired in March 1309 to Kerak, whence he sent his abdication to Cairo; in consequence of which, on the 5th of April 1309, Bibars Jashengir was proclaimed sultan, with the title Malik al-Maqaffar. This prince was originally a freedman.
of Kalûn, and was the first Circassian who ascended the throne of Egypt. Before the year was out the new sultan had been rendered unpopular by the occurrence of a famine, and Malik al-Nâṣir was easily able to induce the Syrian amirs to return to his allegiance, in consequence of which Bihars in his turn abdicated, and Malik al-Nâṣir re-entered Cairo as sovereign on the 5th of March, 1340. He soon found the means to execute both Bihars and Sard, while other amirs who had taken refuge under the former régime fled to the Mongols. The relations between their Ikhnân and the Egyptian sultan continued strained, and the 8th Ikhnân Oeljeitu (1304-1316) addressed letters to Philip the Fair and the English king Edward I. (answered by Edward II. in 1307), desiring aid against Malik al-Nâṣir; and for many years the courts of the sultans and the Ikhnân continued to be the refuge of malcontents from the other kingdom. Finally in 1342 terms of peace and alliance were agreed on between the sultan and Adbâ Salîm the 9th Ikhnân. The sultan also entered into relations with the Mongols of the Golden Horde and in 1339 married a daughter of the reigning prince Uzbeg Khan (see MONGOLS: Golden Horde). Much of Malik al-Nâṣir's third administration was spent in raids into Nubia, where he endeavoured to set up a creature of his own as sovereign, in attempts at bringing the Bedouins of south-eastern Egypt into subordination to himself in persecuting the Nossiris, whose heresy became formidable about this time. Like other Egyptian sultans he made considerable use of the Assassins, 124 of whom were sent by him into Persia to execute Kara Sonkor, at one time governor of Damascus, and one of the murderers of Malik al-Ashraf; but they were all outwitted by the exile, who was finally poisoned by the Ikhnân in recompense for a similar service rendered by the Egyptian sultan. For a time Malik al-Nâṣir was recognized as suzerain in north Africa, the Arabian Trak and Asia Minor, but he was unable to make any permanent conquests in any of these countries. He brought Mîdina, which had previously been governed by independent sherifs, to acknowledge his authority. His diplomatic relations were more extensive than those of any previous sultan, and included Bulgarian, Indian, and Abyssinian potestats, as well as the pope, the king of Aragon and the king of France. He appears to have done his utmost to protect his Christian subjects, incurring thereby the reproaches of the more fanatical Moslems, especially in the year 1320 when owing to incendiaries in Cairo there was danger of a general massacre of the Christian population. His internal administration was marked by gross extravagance, which led to his viziers being forced to practise violent extortion for which they afterwards suffered. He paid considerable attention to sheep-breeding and agriculture, and by a canal which he had dug from Fuhâ to Alexandria not only assisted commerce but benefited the fodder lands under cultivation. His tax for building and street improvements was one Idris, and his example was followed by the governors of other great cities in the empire, notably Aleppo and Damascus. He paid exceptionally high prices for Mamelukes, many of whom were sold by their Mongol parents to his agents, and accustomed them to greater luxury than was usual under his predecessors. In 1315 he instituted a survey of Egypt, and of the twenty-four parts into which it was divided ten were assigned to the sultan and his family, and the ten remaining being a large majority which he wished to abolish a variety of vexatious imposts, and the new budget fell less heavily on the Christians than the old. Among the literary ornaments of his reign was the historian and geographer Ismâ'îl Abûlfezâ (q.v.), to whom Malik al-Nâṣir restored the government of Hamath, which had belonged to his ancestors, and even gave the title sultan. He died on the 7th of June, 1341. The son, Abu Bakr, to whom he had left the throne, was able to maintain himself only a few months on it, being compelled to abdicate on the 4th of August, 1341 in favour of his infant brother Kuchuk; the revolution was brought about by Kausûn, a powerful Mame- luke of the preceding monarch. This person's authority was, however, soon overthrown by a party formed by the Syrian prefects, and on the 11th of January Malik al-Nâṣir Ahmad, an elder son of the former sultan of the same title, was installed in his place, though he did not actually arrive in Cairo till the 6th of November, being unwilling to leave Kerak, where he had been living in retirement. After a brief sojourn in Cairo he speedily returned thither, thereby forfeiting his throne, which was conferred by the amirs on his brother Ismâ'îl al-Mâlik al-Sâlih (June 27th, 1344). This sultan was mainly occupied during his short reign with besieging and taking Kerak, whither Ahmad had withdrawn the latter part of 1342 and himself died on the 3rd of August, 1345, when another son of Malik al-Nâṣir, named Sha'bân, was placed on the throne. The constant changes of sultan led to great disorder in the provinces, and many of the subject principalities endeavoured to shake off the Egyptian yoke. Sha'bân proved no more competent than his predecessors, being given to open debauchery and profligacy, an example followed by his amirs; and fresh discontent led to his being deposed by the Syrian amirs, when his brother Hâjî was proclaimed sultan in his place (September 18th, 1346). Hâjî was deposed and killed on the 10th of December, 1347, and another infant son of Malik al-Nâṣir, Hâsan, who took his father's title, was proclaimed, the real power being shared by three amirs, Sheikhun,Menjek and Yelbogha Arus. During this reign (1348-1349) Egypt was visited by the "Black Death," which is said to have carried off 900,000 of the inhabitants. Hâjî and two of his nephews also died in the beginning of 1351 and the sultan got rid of his guardians and attempted to rule by himself; but though successful in war, his arbitrary measures led to his being dethroned on the 21st of August, 1351 by the amirs, who proclaimed his brother Sâlih with the title Malik al-Sâlih. He too was only fourteen years of age. The power was contested for by various groups of amirs, whose struggles ended with the deposition of the sultan Sâlih on the 20th of October, 1354, and the reinstatement of his brother Hâsân, who was again dethroned on the 16th of March, 1356 by an amir Yelbogha, whom he had offended, and who, having got possession of the sultan's person, murdered him. The next day a son of the dethroned sultan Hâjî was proclaimed sultan with the title Malik al-Manşûr. On the 29th of May, 1363 this sultan was also dethroned on the ground of incompetence, and his place was given to another grandson of Malik al-Nâṣir, Sha'bân, son of Hâsân, then ten years old. The amir Yelbogha at first held all real power and is said to have acquired a degree of authority which no other subject ever held. During this reign, on the 8th of October, 1365, a landing was effected at Alexandria by a Frankish fleet under Peter I. of Cyprus, which presently took possession of the city; the Franks were speedily compelled to embark again after plundering the city, for which compensation was afterwards demand by Yelbogha from the Christian population of Egypt and Syria. Alexandria was further made the object of a viceregal, being proceeded on by hand of arms. On the 21st of December, 1365 Yelbogha was himself attacked by the sultan, captured and slain. His successor in the office of first minister was a mere tool in the hands of his Mamelukes, who compelled him to institute and depose governors, &c., at their pleasure. In 1374 the Egyptians raided Cilicia and captured Leo VI., prince of Lesser Armenia, which now became an Egyptian province with a Moslem governor. On the 15th of March, 1377 the sultan was murdered by the Mamelukes, owing to a dispute among them which had been going on for some time. He too was an infant, the son of the late sultan 'Ali, a lad of eight years, was proclaimed with the title Malik al-Manşûr; the power was in the hands of the ministers Kartai and Ibek, the latter of whom overthrew the former and with the aid of his own Mamelukes, Bereke and Barkîk. An insurrection in Syria which spread to Egypt presently caused the fall of Ibek, and led to the occupation of the highest posts by the Circassian freedmen Berekeh and Barkîk, of whom the latter invested Ascur, the former and usurping the sultan's place; on the 19th of May, 1381, when the sultan 'Ali died, his place was given to an infant brother Hâjî, but on the 26th of November, 1382, Barkîk set this child aside and had himself proclaimed sultan (with the title Malik al-Zahir), thereby ending the Bahri dynasty and commencing that of the Circassians. For a short period, however, Hâjî
was restored, when on the 1st of June 1389 Cairo was taken by Yelbgoha, governor of Damascus, and Barkuk expelled; Haji reigned at first under the guardianship of Yelbgoha, who was then overthrown by Mintash; Barkuk, who had been relegated to Kerak, succeeded in again forming a party, and in a battle fought at Shakhb, January 1396, succeeded in gaining possession of the person of the sultan Haji, and on the 21st of January he was again proclaimed sultan in Cairo. The sultan (1421) had Mameluk Barkuk presently entered into relations with the Ottoman sultan Bayezid I., and by slaying an envoy of Timur incurred the displeasure of the world-conqueror; and in 1394 led an army into Syria with the view of restoring the Jelairid Ilkhan Ahmad to Bagdad (as Barkuk's vassal), and meeting the Mongol invasion. Barkuk, however, died (June 20th, 1399) before Timur had time to invade Syria. According to the custom that had so often proved disastrous, a young son of Barkuk, Paraj, then aged thirteen, was appointed sultan under the guardianship of two amirs. Incursions were immediately made by the Ottoman sultan into the territory of Egyptian vassals at Derendeh and Albistan (Abelstin), and Malatia was besieged by his forces. Timur, who was at this time beginning his campaign against Bayezid, turned his attention first to Syria, and on the 30th of October 1400 defeated the Syrian amirs near Aleppo, and soon got possession of the city and the citadel. He proceeded to take Hamah, Homs (Emesa) and other towns, and on the 20th of December started for Damascus. An endeavour was made by the Egyptian sultan to relieve Damascus, but the news of an insurrection in Cairo caused him to retire and leave the place to its fate. In the first three months of 1401 the whole of Northern Syria suffered from Timur's marauders. In the following year (September 29th, 1402) Timur who had in the interval inflicted a crushing defeat on the Ottoman sultan, sent to demand homage from Faraj, and his demand was readily granted, together with the delivery of the princes who had sought refuge from Timur in Egyptian territory. The death of Timur in February 1405 restored Egyptian authority in Syria, which, however, became a rendezvous for all who were discontented with the rule of Faraj and his amirs, and two months after Timur's death was in open rebellion against Faraj. Although Faraj succeeded in defeating the rebels, he was compelled by insubordination on the part of his Circassian Mamelukes to abdicate (September 20th, 1405), when his brother Abd al-Ras was proclaimed with the title Malik al-Mansur; after two months this prince was deposed, and Faraj, who had been in hiding, retired. Most of his reign was, however, occupied with revolts on the part of the Syrian amirs, to quell whom he repeatedly visited Syria; the leaders of the rebels were the amirs Newruz and Sheik Mahommed, afterwards sultan. Owing to disturbances and misgovernment the population of Egypt and Syria is said to have shrunk to a third in his time, and he offended public sentiment not only by debauchery, but by having his image stamped on his coins. On the 23rd of May 1417, after being defeated and shut up in Damascus, he was compelled by Sheik Mahommed to abdicate, and an Abbasid caliph, Musta'in, was proclaimed sultan, only to be forced to abdicate on the 6th of November of the same year in Sheik's favour, and the title Malik al-Mansur. Newruz having been previously sent to Syria, where he was to be autocrat by the terms of their agreement. In the struggle which naturally followed between the two, Newruz was shut up in Damascus, defeated and slain. Sheik himself invaded Asia Minor and forced the Turkoman states to acknowledge his suzerainty. After the sultan's return they soon rebelled, but were again brought into subjection by Sheik's son Ibrahim; his victories took the envy of his father, who is said to have poisoned him. Sheik himself died a few months after the decease of his son (January 13th, 1421), and another infant son, Ahmad, was proclaimed with the title Malik al-Mogafar, the proclamation being followed by the usual dissensions between the amirs, ending with the assumption of supreme power by the amir Tatar, who, after defeating his rivals, on the 20th of August 1421, thus he proclaimed sultan with the title Malik al-Zahir. This usurper, however, died on the 30th of November of the same year, leaving the throne to an infant son Mohammed, who was given the title Malik al-Saltik; the regular intrigues between the amirs followed, leading to his being dethroned on the following 1st of April 1422, when the amir appointed to be his tutor, Barsbai, was proclaimed sultan with the title Malik al-Alshaf. This sultan avenged the attacks on Alexandria, and the state was made by Cyprus with the fleet which burned Limassol, and another which took Famasguta (August 4th, 1425), but failed in the endeavours to annex the island permanently. An expedition sent in the following year (1426) succeeded in taking captive the king of Cyprus, who was brought to Cairo and presently released for a ransom of 200,000 dinars, on condition of acknowledging the suzerainty of the Egyptian sultan and paying him an annual tribute. Barsbai appears to have excelled his predecessors in the invention of devices for exacting money from merchants and pilgrims, and in juggling with the exchange. This led to a naval demonstration on the part of the Venetians, who secured better terms for their trade, and to the seizure of Egyptian vessels by the king of Aragon and the prince of Catalonia. In a census made during Barsbai's reign, it was found that the total number of towns and villages in Egypt had sunk to 2,170, whereas in the 4th century a.D. it had stood at 10,000. Much of Barsbai's attention was occupied with raids into Asia Minor, where the Dhu-l-Kadiri Turkomans frequently rebelled, and with wars against Kara Yelek, prince of Amid, and Shah Rokk, son of Timur. Barsbai died on the 7th of June 1438. In accordance with the custom of his predecessors he left the throne to a son still in his minority, Abul-Makhsud Tursaf, who took the title Malik al-Asfa, but as usual after a few months he was displaced by the regent Jakmsk, who on the 9th of September 1438 was proclaimed sultan with the title Malik al-Zahir. In the years 1442-1444 this sultan sent three fleets against Rhodes, where the third effected a landing, but was unable to make any permanent conquest. In consequence of a lengthy illness Jakmsk abdicated on the 1st of February 1453, when his son Othman was proclaimed sultan with the title Malik al-Mansur. Though not a minor, he had no greater success than the sons of the usurpers who preceded him, being dethroned after six months (March 15th, 1453) in favour of the amir Inal al-Alat, who took the title Malik al-Alshaf. His reign was marked by friendly relations with the Ottoman sultan Mahommed II., whose capture of Constantinople (1453) was the cause of great rejoicing in Egypt, but also by violent excesses on the part of the Mamelukes, who dictated the sultan's policy. On his death on the 26th of February 1461 his son Ahmad was proclaimed sultan with the title Malik al-Mu'ayyad; he had the usual fate of sultans' sons, earned in this case by an attempt to bring the Mamelukes under discipline; he was compelled to abdicate on the 28th of June 1461, when the amir Khedonah, who had served as a general, was proclaimed sultan. Unlike the other Mameluke sovereigns, who were Turks or Circassians, this man had originally been a Greek slave. In his reign (1463) there began the struggle between the Egyptian and the Ottoman sultanes which finally led to the submission of Egypt to the Ottomans. This dispute began with a struggle over the succession in the principality of Karaman, where the two sultans favoured rival candidates, and the Ottoman sultan Mahommed II. supported the claim of his candidate with force of arms, obtaining as the price of his assistance several towns in which the suzerainty of the Egyptian sultan had been acknowledged. Open war did not, however, break out between the two states in Karaman; in this the Ottoman sultan is said to have taken money to permit innocent persons to be ill-treated or executed. He died on the 9th of October 1467, when the Atabeg Velsai was selected by the Mamelukes to succeed him, and was proclaimed sultan with the title Malik al-Zahir. This person, proving incompetent, was deposed by a revolution of the Mamelukes on the 4th of December 1467, when the Atabeg Timurbaogha
was proclaimed with the title Malik al-Zahir. In a month’s time, however, there was another palace revolution, and the new Atabeg Kazi Bey or Kastei (January 31st, 1406) was proclaimed sultan, the dethroned Timurbegha being, however, permitted to go free whither he pleased. Kazi Bey was of Timurbegha’s line; he spent in struggles with Ustn Hasan, prince of Diarbekr, and Shah Siwâr, chief of the Dhu’l-Kâtîr Turksmanos. He also offended the Ottoman sultan Bayezid II. by entertaining his brother Jem, who was afterwards poisoned in Europe. Owing to this, and also to the fact that an Indian embassy to the Ottoman sultan was intercepted by the agents of Kazi Bey, Bayezid II. declared war against Egypt, and seized Adana, Tarsus, and other places on the mainland of the empire, endeavoring to starve the fortresses made by Kazi Bey, whose generals inflicted a severe defeat on the Ottoman invaders. In 1401, however, after the Egyptians had repeatedly defeated the Ottoman troops, Kazi Bey made proposals of peace which were accepted, the keys of the towns which the Ottomans had seized being restored to the Egyptian sultan. Kazi Bey endeavoured to assist his co-religionists in Spain who were threatened by King Ferdinand, by threatening the pope with reprisals on Syrian Christians, but without effect. As the consequence of a palace intrigue, which Kazi Bey was too old to quell, on the 7th of August 1406, a day before his death, his son Mohammed was proclaimed sultan with the title Malik al-Nâṣir; this was in order to put the supreme power into the hands of the Atabeg Kânshû, since the new sultan was only fourteen years old. An attempt of the Atabeg to oust the new sultan, however, failed. After a reign of little more than two years, filled mainly with struggles between rival amirs, Malik al-Nâṣir was murdered (October 25th, 1408), and his uncle and vizier Kânshû proclaimed sultan with the title Malik al-Zahir. His reign lasted only about twenty months; on the 30th of June 1500 he was dethroned by Tamânbey, who caused Jân Belât, the Atabeg, to be proclaimed sultan. A few months later Tamânbey, at the suggestion of Kasrawah, governor of Damascus, whom he had been sent to reduce to subjection, ousted Jân Belât, and was himself proclaimed sultan with the title Malik al-Âdil (January 25th, 1501). His reign lasted only one hundred days, when he was displaced by Kânshû al-Chârî (April 20th, 1501). His reign was remarkable for a naval conflict between the Egyptians and the Portuguese, whose fleet interfered with the pilgrim route from India to Mecca, and also with the trade between India and Egypt; Kânshû caused a fleet to be built which fought naval battles with the Portuguese with varying results.

In 1515 there began the war with the Ottoman sultan Selim I., which led to the close of the Mameluks period, and the incorporation of Egypt and its dependencies in the Ottoman empire (see TURKEY: History). Kânshû was charged by Selim with giving the envos of the Şafawid Isma’il passage through Syria on their way to Venice to form a confederacy against the Turks, and with harbouring various refugees. The actual declaration of war was not made by Selim till May 1515, when the Ottoman sultan had made all his preparations; and at the battle of Merj Dabik, on the 24th of August 1515, Kânshû was defeated by the Ottoman forces and fell fighting. Syria passed quickly into the possession of the Turks, whose advent was in many places welcome as meaning deliverance from the Mamelukes. In Cairo, when the news of the defeat and death of the Egyptian sultan arrived, the governor who had been left by Kânshû, Tamânbey, was proclaimed sultan (October 17th, 1516). On the 20th of January 1517 Cairo was taken by the Ottomans, and Selim shortly after declared sultan of Egypt. Tamânbey continued the struggle for some months, but was finally defeated, and after being captured and kept in prison seventeen days was executed on the 15th of April 1517.

(8) The Turkish conquest.—The sultan Selim left with his viceroy Khair Bey a guard of 5000 janissaries, but otherwise made few changes in the administration of the country. The register by which a great portion of the land was a fief of the Mamelukes was left unchanged, and it is said that a proposal made by the sultan’s vizier to appropriate these estates was punished with death. The Mameluks amirs were to be retained in office as heads of twelve sanjaks into which Egypt was divided; and under the next sultan, Suleiman I., two chambers were created, called respectively the Greater and the Lesser Divan, in which both the army and the Egyptian provinces were represented, and by which they could aid the pasha by their deliberations. Six regiments altogether were constituted by the conqueror Selim for the protection of Egypt; to these Suleiman added a seventh, of Circassians. As will be seen from the tables, it was the practice of the Porte to change the governor of Egypt at very short intervals—after a year or even some months. The third governor, Ahmad Pasha, hearing that orders for this execution had come from both the army and the sultan’s council, put a stop to the extortion called Tulbi, a forced payment exacted by the troops from the inhabitants of the country by the fiction of debts requiring to be discharged, which led to grievous ill-usage. In 1609 something like civil war broke out between the army and the pasha, who had on his side some loyal regiments and the Bedouins. The soldiers went so far as to choose a sultan, and to divide provisionally the regions of Cairo between them. They were defeated by the governor Mahommed Pasha, who on the 5th of February 1610 entered Cairo in triumph, executed the ringleaders, and banished many others to Yemen. The contemporary historian speaks of this event as a second conquest of Egypt for the Ottomans. A great financial reform was now effected by Mahommed Pasha, who readjusted the burdens imposed on the different communities of Egypt in accordance with their means. With the troubles that beset the metropolis of the Ottoman empire, the governors appointed thence came to be treated by the Egyptians with continually decreasing respect. In July 1625 there came an order from the Porte dismissing Muhsàf Pasha and appointing ’Ali Pasha governor in his place. The officers met and demanded from the newly-appointed governor’s deputy the customary gratuity; when this was refused they sent letters to the Porte declaring that they wished to have Muhsàf Pasha and not ’Ali Pasha as governor. Meanwhile ’Ali Pasha had arrived at Alexandria, and was met by a deputation from Cairo telling him that he was not wanted. He returned a mild answer; and, when a rejoinder came in the same style as the first message, he had the leader of the deputation arrested and imprisoned. Hereupon the garrison of Alexandria attacked the castle and rescued the prisoner; whereupon ’Ali Pasha was compelled to embark. Shortly after a rescript arrived from Constantinople confirming Muhsàf Pasha in the governorship. Similarly in 1631 the army took upon themselves to depose the governor Muhsàf Pasha, in which matter at his execution Khair Bey, an officer whom it is said he formerly commanded an Egyptian force required for service in Persia. The pasha was ordered either to hand over the executioners to vengeance or to resign his place; as he refused to do either, he was compelled to do the latter, and presently a rescript came from Constantinople, approving the conduct of the army and appointing one Khâlîl Pasha as Muhsàf’s successor. Not only was the governor unsupported by the sultan against the troops, but each new governor regularly inflicted a fine upon his outgoing predecessor, under the name of money due to the
treasury; and the outgoing governor would not be allowed to leave Egypt till he had paid it. Besides the exactions to which this practice gave occasion the country suffered greatly in these centuries from famine and pestilence. The latter in the spring of 1619 is said to have carried off 633,000 persons, and in 1643 completely destroyed 370 villages.

By the 18th century the importance of the pasha was quite superseded by that of the beys, and two offices, those of Sheik al-Balad and Amir al-Hājj, which were held by these persons, represented the real headship of the community. The process by which this state of affairs came about is somewhat obscure, owing to the want of good chronicles for this Turkish period of Egyptian history. In 1767 the Sheik al-Balad, Osman Iyyāz, was found at the head of one of two Mameluke factions, the Qasimites and the Fiqārites, between whom the seeds of enmity were sown by the pasha of the time, with the result that a fight took place between the factions outside Cairo, lasting eighty days. At the end of that time Qasim Iyyāz was killed and the office which he had held was given to his son Isma'il. Isma'il held this office for sixteen years, while the pashas were constantly being changed, and succeeded in reconciling the two factions of Mamelukes. In 1774 this person was assassinated through the machinations of the pasha, and Shirkas Bey, of the opposing faction, elevated to the office of Sheik al-Balad in his place. He was soon driven from his post by one of his own faction called Dhu'l-Fiqār, and fled to Upper Egypt. After a short time he returned at the head of an army, and some engagements ensued, in the last of which Shirkas Bey met his end by drowning; Dhu'l-Fiqār was himself assassinated in 1780 shortly after this event. His place was filled by Ottoman Bey, who had served as his general in this war. In 1743 Othman Bey, who had governed with wisdom and moderation, was forced to fly from Egypt by the intrigues of two adventurers, Ibrahim and Ridwan Bey, who, when their scheme had succeeded, began a massacre of beys and others thought to be opposed to them; they then proceeded to govern Egypt jointly, holding the two offices mentioned above in alternate years. An attempt made by one of the pashas to rid himself of these two persons by a coup d'état signally failed owing to the loyalty of their armed supporters, who released Ibrahim and Ridwan from prison and compelled the pasha to fly to Constantinople. An attempt made by a subsequent pasha in accordance with secret orders from Constantinople was so far successful that some of the beys were killed. Ibrahim and Ridwan escaped, and compelled the pasha to resign his government and return to Constantinople. Ibrahim shortly afterwards fell by the hand of an assassin who had aspired to occupy one of the vacant beyships himself, which was conferred instead on 'Ali, who as 'Ali Bey was destined to play an important part in the history of Egypt. The murder of Ibrahim Bey took place in 1755, and his colleague Ridwan perished in the disputes that followed upon it.

'Ali Bey, who had first distinguished himself by defending a caravan in Arabia against bandits, set himself the task of avenging the death of his former master Ibrahim; and spent eight years in purchasing Mamelukes and winning other adherents. He thereby excited the suspicions of the Sheik al-Balad Khalil Bey, who organized an attack upon him in the streets of Cairo, in consequence of which he fled to Upper Egypt. Here he met one Shih Bey, who had injuries to avenge on Khalil Bey, and the two organized a force with which they returned to Cairo and defeated Khalil, who was forced to fly to Tanta, where for a time he concealed himself; eventually, however, he was discovered, sent to Alexandria and finally strangled.

The date of 'Ali Bey's victory was 1764 A.H. (a.d. 1750), and after it he was made Sheik al-Balad. In that capacity he executed the murderer of his former master Ibrahim; but the resentment which this act aroused among the beys caused him to leave his post and fly to Syria, where he won the friendship of the governor of Acre, Zahir b. Omar, who obtained for him the good will of the Porte and reinstatement in his post as Sheik al-Balad. In 1766, after the death of his supporter the grand vizier Rakhir Pasha, he was again compelled to fly from Egypt to Yemen, but in the following year he was told that his party at Cairo was strong enough to permit of his return. Resuming his office he raised eighteen of his friends to the rank of bey, among them Ibrahim and Murad, who were afterwards at the head of the forces as well as Mahommed Abu'l-Dhabab, who was connected with the rest of 'Ali Bey's career. He appears to have done his utmost to bring Egyptian affairs into order, and by very severe measures repressed the brigandage of the Bedouins of Lower Egypt. He appears to have aspired to found an independent monarchy, and to that end endeavoured to disband all forces except those which were exclusively under his own control. In 1769 a demand came to 'Ali Bey for a force of 12,000 men to be employed by the Porte in the Russian war. It is suggested, however, at Constantinople that 'Ali would employ this force when he collected it for securing his own independence, and a messenger was sent by the Porte to the pasha with orders for his execution. 'Ali, being apprised by his agents at the metropolis of the despatch of this messenger, ordered him to be waylaid and killed; the dispatches were seized and read by 'Ali before an assembly of the beys, who were assured that the order for execution applied to all alike, and he urged them to fight for their lives. His proposals were received with enthusiasm by the beys whom he had created. Egypt was declared independent and the pasha given forty-eight hours to quit the country. Zahir Pasha of Acre, to whom was sent official information of the step taken by 'Ali Bey, promised his aid and kept his word by compelling an army sent by the pasha of Damascus against Egypt to retreat.

The Porte was not able at the time to take active measures for the suppression of 'Ali Bey, and the latter endeavoured to consolidate his dominions by sending expeditions against marauding tribes, both in north and south Egypt, reforming the finance, and improving the administration of justice. His son-in-law, Abu'l-Dhabab, was sent to subject the Hawwârah, who had occupied the land between Assuan and Assiut, and a force of 20,000 was sent to conquer Yemen. An officer named Isma'il Bey was sent with 5000 to acquire the eastern shore of the Red Sea, and one named Hasán Bey to occupy Jidda. In six months the greater part of the Arabian peninsula was subject to 'Ali Bey, and he appointed as sherif of Mecca a cousin of his own, who bestowed on 'Ali by an official proclamation the titles Sultan of Egypt and Khâkân of the Two Seas. He then, in virtue of this authorization, struck coins in his own name (1185 a.h.) and ordered his name to be mentioned in public worship.

His next move turned out fatally; Abu'l-Dhabab was sent with a force of 30,000 men in the same year (a.d. 1771) to conquer Syria; and agents were sent to negotiate alliances with Venice and Russia. Abu'l-Dhabab's progress through Palestine and Syria was triumphant. Reinforced by 'Ali Bey's ally Zahir, he easily took the chief cities, ending with Damascus; but at this point he appears to have entered into secret negotiations with the Porte, by which he undertook to restore Egypt to Ottoman suzerainty. He then proceeded to evacuate Syria, and marched with all the forces he could collect to Upper Egypt, occupying Assiut in April 1772. Having collected some additional troops from the Bedouins, he marched on Cairo. Isma'il Bey was sent by 'Ali Bey with a force of 3000 to check his advance; but at Baâsin Isma'il with his troops joined Abu'l-Dhabab. 'Ali Bey intended at first to defend himself so long as possible in the citadel at Cairo; but receiving information to the effect that his friend Zahir of Acre was still willing to give him refuge, he left Cairo for Syria (8th of April 1772), one day before the entrance of Abu'l-Dhabab.

At Acre 'Ali's fortune seemed to be restored. A Russian vessel anchored outside the port, and, in accordance with the agreement which he had made with the Russian empire, he was supplied with stores and ammunition, and a force of 3000 Albanians. He sent one of his officers, 'Ali Bey al-Tanti, to recover the Syrian towns evacuated by Abu'l-Dhabab, and now in the possession of the Porte. He himself took Jaffa and Gaza,
the former of which he gave to his friend Zāhir of Acre. On the 1st of February 1773 he received information from Cairo that Abūl-Dhahab had made himself Sheik al-Balad, and in that capacity was reclaiming waste portions, which after making Egypt with one voice call for the revocation of 'All Bey. He accordingly started for Egypt at the head of an army of 8000 men, and on the 10th of April met the army of Abūl-Dhahab at Sāliḥiyya. 'All's forces were successful at the first engagement; but when the battle was renewed two days later he was deserted by some of his officers, and prevented by illness and wounds from himself taking the conduct of affairs. The result was a complete defeat for his army, after which he declined to oppose the new ruler, and was captured at his command, and brought to Cairo, where he died seven days later.

After 'All Bey's death Egypt became once more a dependency of the Porte, governed by Abūl-Dhahab as Sheik al-Balad with the title pasha. He shortly afterwards received permission from the Porte to invade Syria, with the view of punishing 'All Bey's supporter Zāhir, and left as his deputies in Cairo Isma'il Bey and Ibrāhīm Bey, who, by deserting 'Ali at the battle of Sāliḥiyya, had brought about his downfall. After many taking cities in Palestine Abūl-Dhahab died, the news of which being unknown to Murād Bey (another of the deserts at Sāliḥiyya) brought his forces back to Egypt (26th of May 1775).

Isma'il Bey now became Sheik al-Balad, but was soon involved in a dispute with Ibrāhīm and Murād, who after a time succeeded in driving Isma'il out of Egypt and establishing a joint rule (as Sheik al-Balad and Amir al-Hājī respectively) similar to that which had been tried previously. The two were soon involved in quarrels, which at one time threatened to break out into open war; but this catastrophe was averted, and the joint rule was maintained till 1786, when an expedition was sent by the Porte to restore Ottoman supremacy in Egypt. Murād Bey attempted to resist, but was easily defeated; and he with Ibrāhīm decided to fly to Upper Egypt and await the trend of events. On the 1st of August 1782 the Turkish commander entered Cairo, and, after some violent measures had been taken for the restoration of order, Isma'il Bey was again made Sheik al-Balad and a new pasha installed as governor. In January 1791 a terrible plague began to rage in Cairo and elsewhere in Egypt, to which Isma'il Bey and most of his family fell victims. Owing to the need for competent rulers Ibrāhīm and Murād Bey were sent for from Upper Egypt and resumed their dual government. These two persons were still in office when Bonaparte entered Egypt.

There is much in the Arabic literature of the time about the composition, and Arab authors accustomed to travel from place to place to collect traditions and obtain oral instruction from contemporary authorities, the importance of the memory of Mecca and Medina, the literary history of Egypt cannot be dissociated from that of the other Moslem countries in which Arabic was the chief literary vehicle. Hence the list of authors connected with Egypt, which occupies pages 161-275 of Suyūtī's work, Hāras al-mudāahara fi akhkhār Mihr wa-dakhrah (Cairo, 1321 A.H.), contains the names of persons like Muḥammad b. Mubāh, who stayed there for a short time in the service of some patron: Abūl-Tāmām, who lived there before he acquired fame as a poet; Umāra of Yemen, who came there at a mature age to spend some years in the service of Fāṭimite viziers; each of whom figures in lists of authors belonging to some other country also. So long as the centre of the Islamic world was not Egypt, the best talent was attracted elsewhere; but after the fall of Bagdad, Cairo became the chief seat of Islamic learning, and this rank, chiefly owing to the university of Al-Azhar, has been continued to the present. The following is a list of composers special histories of Egypt: Ibn 'Abd al-Hakam, d. 357 A.H.: 'Abd al-Rahmān b. Yūsūs, d. 347; Muḥammad b. Yūsuf al-Qāsimi, d. somewhat later: Ibn Zālīl, d. 387; Abūl-Mulk Muḥammad al-Mussābiḥī, d. 420; Muḥammad b. Sālima al-Qādī, d. 454. Jamāl al-dīn 'Ali al-Qīsī, d. 568. Jamāl al-dīn al-Hasān al-Habībī, d. 625. Muḥammad b. 'Abd al-Mu'min, d. 664. Muḥammad b. 'Ali al-Dirārī, d. 678. Muḥammad b. Yūsuf al-Fārisī, d. 697. Muḥammad b. 'Abd al-Rahmān b. Idrīs, d. 707. Abūl-Qāsim al-Qāsimī, d. 715. Muḥammad b. 'Abd al-Karim, d. 724. Muḥammad b. Sāliḥ al-Hakamī, d. 725. Muḥammad b. Ṭūmarī, d. 740. Muḥammad b. Ṭūmarī, d. 740. Muḥammad al-Hasān al-Shihābī, d. 765. He was the founder of one of the schools of theological distinction, and the best-known among them are Sa'id b. Bītrq, Muḥammad al-Minhāmī, and Ibn Bītāq. Of Egyptian miscellaneous writers two of the most celebrated are Ibn Dā'īq, the Ta' ṭībī, d. 869; and Jalāl al-Dīn al-Qāsimī, d. 877.

(5) From the French Occupation to the Rise of Mahrēt Ali.—The ostensible object of the French expedition to Egypt was to reinstate the authority of the Sublime Porte, and suppress the Mameluks; and in the proclamation printed with the Arabic types brought from the Propaganda press, and issued shortly after the taking of Alexandria, Bonaparte declared that he had conquered the Prophet Mameluk and the Karon far more than the Mameluks ever conquered theھتیمک، and that the French were equal except so far as they were distinguished by their intellectual and moral excellences, of neither of which the Mameluks had
any great share. In future all posts in Egypt were to be open to all classes of the inhabitants; the conduct of affairs was to be committed to the men of talent, virtue, and learning; and in proof of the statement that the French were sincere Moslems the overthrow of the papal authority in Rome was alleged. The French had no doubt of their final success. The negotiations of the French to the Porte, villages and towns which capitated to the invaders were required to hoist the flags of both the Porte and the French republic, and in the thanksgiving prescribed to the Egyptians for their deliverance from the Mamelukes, prayer was to be offered for both the sultan and the French army. It does not appear that the proclamation convinced many of the Egyptians of the truth of these professions. After the battle of Ambabah, at which the forces of both Murd Bey and Ibrahim Bey were dispersed, the populace readily plundered the belongings of the beys, and a deputation was sent from al-Azhar to Bonaparte to ascertain his intentions; these proved to be a repetition of the terms of his proclamation, and, though the combination of loyalty to the French with loyalty to the sultan was unintelligible, a good understanding was at first established between the invaders and the Egyptians. A municipal council was established in Cairo, consisting of persons taken from the ranks of the sheiks, the Mamelukes and the French; the French had already detached from Alexandria and other important towns. This council did little more than register the decrees of the French commander, who continued to exercise dictatorial power. The destruction of the French fleet at the battle of the Nile, and the failure of the French forces sent to Upper Egypt (where they reached the first cataract) to obtain possession of the person of Murd Bey, shook the faith of the Egyptians in their invincibility; and in consequence of a series of unwelcome innovations the relations between conquerors and conquered grew daily more strained, till at last, on the occasion of the introduction of a house tax, an insurrection broke out in Cairo on the 22nd of October 1798, of which the headquarters were in the Moslem university of Azhar. On this occasion the French general Dupuy, lieutenant-governor of Cairo, was killed. The prompt measures of Bonaparte, aided by the arrival from Alexandria of General J. B. Kléber, quickly suppressed this rising; but the stabbing of the French cavalry in the mosque of Azhar gave great and permanent offence. In consequence of this affair, the deliberative council was suppressed, but on the 23rd of December a fresh proclamation was issued, reconstituting the two divans which had been created by the Turks; the special divan was to consist of 14 persons chosen by lot out of 60 government nominees, and was to meet daily. The general divan was to consist of functionaries, and to meet weekly. All this was assailed as a measure for the emasculation of the Moslems, and a Copt, General John Hely Hutchinson (afterwards 2nd earl of Donoughmore), and the Turkish under Yüsuf Pasha; after negotiations Belliard agreed to evacuate Cairo and to sail with his 13,734 troops to France. On the 30th of August, Menou at Alexandria was compelled to accept similar conditions, and his force of 10,000 left for Europe in September. This was the termination of the French occupation of Egypt, of which the chief permanent monument was the Description de l’Egypte, compiled by the French savants who accompanied the expedition. Further than this, “it brought to the attention of a few men in Egypt a keen sense of the great advantage of an orderly government, and a warm appreciation of the advance that science and learning had made in Europe” (Hajji Browne. Bonaparte in Egypt and the Egyptians of to-day, 1907, p. 268).

Soon after the evacuation of Egypt by the French, the country became the scene of more severe troubles, in consequence of the attempts of the Turks to destroy the power of the Mamelukes. In defiance of promises to the British government, orders were transmitted from Constantinople to Husain Pasha, the Turkish high admiral, to ensnare and put to death the principal beys. Invited to an entertainment, they were, according to the Egyptian contemporary historian al-Jabarti, attacked on board the flagship; Sir Robert Wilson and M. F. MENGIN, however, state that they were fired on in open boats, in the night of 17th August. They offered an heroic resistance, but were overpowered, and
some killed, some made prisoners; among the last was Osman Bey al-Bardisi, who was severely wounded. General Hutchinson, informed of this treachery, immediately assumed threatening measures against the Turks, and in consequence the killed, wounded and prisoners were given up to him. At the same time Yusuf Pasha arrested all the boys in Cairo, but was shortly compelled by the British to release them. Such was the beginning of the disastrous struggle between the Mamelukes and the Turks. The victorious soldiery sacked the town of Damietta, and were guilty of the barbarities usual with them in such occasions.

Mahomed Khosrev was the first Turkish governor of Egypt after the expulsion of the French. The form of government, however, was not the same as that before the French invasion, for the Mamelukes were not reinstated. The pasha, and through him the sultan, endeavoured on several occasions either to enslave them or to beguile them into submission; but these efforts failing, Mahomed Khosrev took the field, and a Turkish detachment 7000 strong was despatched against them to Damankur, whither they had descended from Upper Egypt, and was defeated by a small force under al-Alli; or, as Mezgin says, by 800 men commanded by al-Bardisi, when all-Alli had left the field. Their ammunition and guns fell into the hands of the Mamelukes.

In March 1803 the British evacuated Alexandria, and Mahomed Bey al-Alli accompanied them to England to consult respecting the means to be adopted for restoring the former power of the Mamelukes, who meanwhile took Minia and interrupted communication between Upper and Lower Egypt. About six weeks after, the Arnaot (or Albanian) soldiers in the service of Khosrev tumultuously demanded their pay, and surrounded the house of the defterdar (or finance minister), who in vain appealed to the pasha to satisfy their claim. The latter opened fire from the artillery of his palace on the insurgent soldiery in the house of the defterdar, across the Esbeckia. The citizens of Cairo, accustomed to such occurrences, immediately closed their shops, and every man who possessed any weapon armed himself. The tumult continued all the day, and the next morning a body of troops sent out by the pasha failed to quell it. Tahir, the commander of the Albanians, then repaired to the citadel, gained admittance through an embrasure, and, having obtained possession of it, began to cannonade the pasha over the roofs of the intervening houses, and then descended with guns to the Esbeckia and laid close siege to the palace. On the following day Mahomed Khosrev made good his escape, with his women and servants and his regular troops, and fled to Damietta by the river. This revolt marks the beginning in Egypt of the breach between the Albanians and Turks, which ultimately led to the expulsion of the latter, and of the rise to power of the Albanian Mehmet Ali (q.v.), who was destined to rule the country for nearly forty years and be the cause of serious, European complications.

Thir Pasha assumed the government, but in twenty-three days he met with his death from exactly the same cause as that of the overthrow of his predecessor. He refused the pay of certain of the Turkish troops, and was immediately assassinated. A desperate conflict ensued between the Albanians and Turks; and the palace was set on fire and plundered. The masters of Egypt were now split into two factions, animated with the fiercest animosity against each other. Mehmet Ali, then in command of an Albanian regiment, became the head of the former, but his party was the weaker, and he therefore entered into an alliance with the Mameluke leaders Ibrahim Bey and 'Osmán Bey al-Bardisi. A certain Ahmed Pasha, who was about to proceed to a province in Arabia, of which he had been appointed governor, was raised to the important post of pasha of Egypt, through the influence of the Turks and the favour of the sultans; but Mehmet Ali, who with his Albanians held the citadel, refused to assent to their choice; the Mamelukes moved over from El-Giza, whither they had been invited by Tahir Pasha, and Ahmed Pasha betook himself to the mosque of al-Zahir, which the French had converted into a fortress. He was compelled to surrender by the Albanians; the two chiefs of the Turks who killed Tahir Pasha were taken with him and put to death, and he himself was detained a prisoner. In consequence of the alliance between Mehemet Ali and al-Bardisi, the Albanians gave the citadel over to the Mamelukes; and soon after, these allies marched against Khosrev Pasha, who having been joined by a considerable body of Turks, and being in possession of Damietta, was enabled to offer an obstinate resistance. After much loss on both sides, he was taken prisoner and brought to Cairo; but he was treated with respect. The victorious soldiery sacked the town of Damietta, and were guilty of the barbarities usual with them in such occasions.

A few days later, Ali Pasha Jazairi landed at Alexandria with an imperial firmán constituting him pasha of Egypt, and threatened the boys, who now were virtual masters of Upper Egypt, as well as of the capital and nearly the whole of Lower Egypt. Mehmet Ali and al-Bardisi therefore descended to Rosetta, which had fallen into the hands of a brother of Ali Pasha, and having captured the town and its commander, al-Bardisi purposed to proceed against Alexandria; but the troops demanded arrears of pay which it was not in his power to give, and the pasha had cut the dyke between the lakes of Aboukir and Mareotis, thus rendering the approach to Alexandria more difficult. Al-Bardisi and Mehemet Ali therefore returned to Cairo. The troubles of Egypt were now increased by an insufficient inundation, and great scarcity prevailed, aggravated by the information to the citizens of his arrival, and the refusal of the pasha in order to pay the troops; while murder and rapine prevailed in the capital, the riotous soldiery being under little or no control. Meanwhile, Ali Pasha, who had been behaving with violence towards the Franks in Alexandria, received a haiiti-sherif from the sultan, which he sent by his secretary to Cairo. It announced that the boys should live peaceably in Egypt, with an annual pension each of fifteen purses (a 'purse'=500 at this time) and other privileges, but that the government should be in the hands of the pasha. To this the boys assented, but with considerable misgivings; for they had intercepted letters from Ali to the Albanians, endeavouring to alienate them from their side to his own. Deceptive answers were returned to these, and Ali was induced by them to advance towards Cairo at the head of 3000 men. The forces of the Mamelukes and of the boys, with the Albanians, encamped near him. Ali Pasha attempted treachery. They next seized his boats conveying soldiers, servants, and his ammunition and baggage; and, following him, they demanded wherefore he brought with him so numerous a body of men, in opposition to usage and to their previous warning. Finding they would not allow his troops to advance, forbidden himself to retreat with them to Alexandria, and being surrounded by the enemy, he would have hazarded a battle, but his men refused to fight. He therefore went to the camp of the boys, and his army was compelled to retire to Syria. In the hands of the boys Ali Pasha again attempted treachery. A horseman was seen to leave his tent one night at full gallop; he was the bearer of a letter to Osman Bey Hasan, the governor of Kine. This offered a fair pretext to the Mamelukes to rid themselves of a man proved to be a pernicious tyrant. He was sent under a guard of forty-five men towards the Syrian frontier; and about a mile from the way that was taken, the news was communication between the two nations, and he was captured with some of his own soldiers he had fallen mortally wounded.

The death of Ali Pasha produced only temporary tranquillity; in a few days (February 12, 1804) the return of Mohammed Bey al-Alfi (called the Great) from England was the signal for fresh disturbances, which, by splitting the Mamelukes into two parties, accelerated their final overthrow. An ancient jealousy existed between al-Alfi and the other most powerful bey, al-Bardisi. The latter was now supreme among the Mamelukes, and this fact considerably heightened their old enmity. While the guns of the citadel, those at Old Cairo, and even those of the palace of al-Bardisi, were thrice fired in honour of al-Alfi, preparations were immediately begun to oppose him. His partisans were collected opposite Cairo, and al-Alfi the Less held Giza; but treachery was among them; Husain Bey (a relative of al-Alfi)
was assassinated by emissaries of al-Bardis, and Mehemet Ali, with his Albanians, gained possession of Giza, which was, as usual, given over to the troops to pillage. In the meanwhile al-Affî the Great embarked at Rosetta, and not apprehending opposition, was on his way to Cairo, when a little south of the town of Manûf he encountered a party of Albanians, and with difficulty made his escape. He gained the eastern branch of the Nile, but the river had become dangerous, and he fled to the desert. He was, however, several times closely escaped, and at last secreted himself among a tribe of Arabs at Râs al-Wâdî. A change in the fortune of al-Bardis, however, favoured his plans for the future. That chief, in order to satisfy the demands of the Albanians for their pay, gave orders to levy heavy contributions from the citizens of Cairo; and this new oppression roused them to rebellion. The Albanians, alarmed for their safety, assured the populace that they would not allow the order to be executed; and Mehemet Ali himself caused a proclamation to be made to that effect. Thus the Albanians became the favourites of the people, and took advantage of their opportunity. Three days later (March 12th, 1804) they beset the house of the aged Ibrahim Bey, and that of al-Affî, both of whom effected their escape with difficulty. The Mamelukes in the citadel directed a fire of shot and shell on the houses of the Albanians which were situated in the Ezbekkâ; but, on hearing of the flight of their chiefs, they evacuated the place; and Mehemet Ali, on gaining possession of it, once more proclaimed Mahomed Khosrow pasha of Egypt. For one day and a half he enjoyed the title; the friends of the late Tahir Pasha then accomplished his second degradation, and Cairo was again the scene of terrible enormities, the Albanians ravaging the houses of the Mamelukes, their harems met with no mercy at their hands. These events were the signal for the reappearence of al-Affî.

The Albanians now invited Ahmed Pasha Khosrow to assume the reins of government, and he without delay proceeded from Alexandria to Cairo. The forces of the partisans of al-Bardis were ravaging the country a few miles south of the capital and intercepting the supplies of corn by the river; a little later they passed to the north of Cairo and successively took Bilbeis and Kalyub, plundering the villages, destroying the crops, and slaughtering the herds of the inhabitants. Cairo was itself in a state of tumult, suffering severely from a scarcity of grain, and the great exactions of the pasha to meet the demands of the turbulent troops, at that time augmented by a Turkish detachment. The shops were closed, and the unfortunate people assembled in great crowds, crying "Ya Lattif! Ya Lattif!" ("O Gracious [God]!") Al-Affî and Osman Bey Hasan had professed allegiance to the pasha; but they soon after declared against him, and they were now approaching from the south; and having repulsed Mehemet Ali, they took the two fortresses of Turâ. These Mehemet Ali speedily retook by night with 4000 infantry and cavalry; but the enterprise was only partially successful. On the following day the other Mamelukes north of the metropolis actually penetrated into the suburbs; but a few days later were defeated in a battle fought at Shubra, with heavy loss on both sides. This reverse in a measure united the two great Mameluke parties, though their chiefs remained at enmity. Al-Bardis passed to the south of Cairo, and the Mamelukes gradually retreated towards Upper Egypt. Thither the pasha despatched three successive expeditions (one of which was commanded by Mehemet Ali), and many battles were fought, but without decisive result.

At this period another calamity befell Egypt; about 3000 Dells (Kurdish troops) arrived in Cairo from Syria. These troops had been sent for by Khosrow in order to strengthen himself against the Albanians; and the events of this portion of the history afford sad proof of their ferocity and brutal enormities, in which they far exceeded the ordinary Turkish soldiers and even the Albanians. Their arrival immediately recalled Mehemet Ali and his party from the war, and instead of aiding Khorshid was the proximate cause of his overthrow.

Cairo was ripe for revolt; the pasha was hated for his tyranny and extortion, and execrated for the deeds of his troops, especially those of the Dells; the sheiks enjoined the people to close their shops, and the soldiers clamoured for pay. At this juncture a firmán arrived from Constantinople confirming on Mehemet Ali the pashalic of Jedda; but the occurences of a few days raised him to that of Egypt.

On the 12th of Safar 1220 (May 12th, 1805) the sheiks, with an immense concourse of the inhabitants, assembled in the house of the kâdî; and the ulâmâ, amidst the prayers and cries of the people, wrote a full statement of the heavy wrongs which they had endured under the administration of the pasha. The ulâmâ, in answer, were desired to go to the citadel; but they were apprised of treachery; and on the following day, having held another council at the house of the kâdî, they proceeded to Mehemet Ali and informed him that the people would no longer submit to Khorshid. "Then whom will ye have?" said he. "We will have thee," they replied, "to govern us according to the laws; for we see in thy countenance that thou art possessed of justice and goodness." Mehemet Ali seemed to hesitate, and the crowds began to increase. On the 18th the struggle began between the two pashas. Khorshid, being informed of the insurrection, immediately prepared to stand a siege in the citadel. Two chiefs of the Albanians joined his party, but many of his soldiers deserted. Mehemet Ali's great strength lay in the devotion of the citizens of Cairo, who looked on him as a deliverer from their afflictions; and great numbers armed themselves, advising constantly with Mehemet Ali, and the sayyîl Omar and the sheikhs at their head, guarding the town at night. On the 19th of the same month Mehemet Ali began to besiege Khorshid. After the siege had continued many days, Khorshid gave orders to cannonade and bombard the town; and for six days his commands were executed with little interruption, the citadel itself also lying between two fires. Mehemet Ali's position at this time was very critical; his troops became mutinous for their pay; the silâhdâr, who had commanded one of the expeditions against the pasha, advanced to the relief of Khorshid; and the latter ordered the Dells to march to his assistance. The firing ceased on the Friday, but began again on the eve of Saturday and lasted until the next Friday. On the day following (May 28th) news came of the arrival of Alexandria of a messenger from Constantinople. The ensuing night in Cairo presented a curious spectacle; many of the inhabitants, believing that this envoy would put an end to their miseries, fired off their weapons as they paraded the streets with bands of music. The silâhdâr, imagining the noise to be a fray, marched in haste towards the citadel, while its garrison salied forth and began throwing up entrenchments in the quarter of Arab al-Yesâr, but were repulsed by the armed inhabitants and the soldiers stationed there; and during all this time the cannonade and bombardment from the citadel, and on it from the batteries on the hill, continued unabated.

The envoy brought a firmán confirming Mehemet Ali and ordering Khorshid to go to Alexandria, there to await further orders; but this he refused to do, on the ground that he had been appointed by a kâti-i-sherîf. The firing ceased on the following day, but the troubles of the people were rather increased than assuaged; murders and robberies were daily committed by the soldiery, the shops were all shut and some of the streets barricaded. While these scenes were being enacted, al-Affî was besieging Damanhur, and the other beys were returning towards Cairo. Khorshid having called them to his assistance; but Mehemet Ali forced them to retreat.

Soon after this, a squadron under the command of the Turkish high admiral arrived at Aboukir Bay, with despatches confirming the firmán brought by the former envoy, and authorizing
Egypt

Mehemet Ali to continue to discharge the functions of governor. Khorshid at last refused to yield; but at length, on condition that his troops should be paid, he evacuated the citadel and embarked for Rosetta.

Mehemet Ali now possessed the title of Governor of Egypt, but beyond the walls of Cairo his authority was everywhere disputed by the beys, who were joined by the army of the Slihuddin of Khorshid; and many Albanians deserted from his ranks. To replenish his empty coffers he was also compelled to levy exactions, principally from the Copts. An attempt was made to esnare certain of the beys, who were encamped north of Cairo. On the 17th of August 1805 the dam of the canal of Cairo was to be cut, and some chiefs of Mehemet Ali's party wrote, informing them that he would go forth early on that morning with most of his troops to witness the ceremony, inviting them to enter and seize the city, and, to deceive them, stipulating for a certain sum of money as a reward. The dam, however, was cut early in the preceding night, without any ceremony. On the following morning, these beys, with their Mameluks, a very numerous body, broke open the gate of the suburb al-Husainia, and gained admittance into the city from the north, through the gate called Bab el-Futuh. They marched along the principal street for some distance, with kettle-drums behind each company, and were received with apparent joy by the citizens. At the mosque called the Ashrafia they separated, one party proceeding to the Azafr and the houses of certain sheiks, and the other remaining along the main fort, being in daily expectation of the arrival of the English army; and at the village of Shubra-ment he was attacked by a sudden illness, and died on the 30th of January 1807, at the age of fifty-five. Thus was the pasha relieved of his two most formidable enemies; and shortly after he defeated Sháhán Bey, with the loss to the latter of his artillery and baggage and 300 men killed or taken prisoners.

On the 17th of March 1807 a British fleet appeared off Alexandria, having on board nearly 5000 troops, under the command of General A. Mackenzie Fraser; and the place was disaffected towards Mehemet Ali, opened its gates to them. Here they first heard of the death of Al-Ali, upon whose co-operation they had counted for their chief hopes of success; and they immediately despatched messengers to his successor and to the other beys, inviting them to Alexandria. The British resident, Major Missett, having represented the importance of seizing Rosetta and Sháhán, to secure supplies for Alexandria, General Fraser, with the consent of the admiral, Sir John Duckworth, detached the 31st regiment and the Chasseurs Britanniques, accompanied by some field artillery under Major-General Wauchope and Brigadier-General Meade, on this service; and these troops entered Rosetta without encountering any opposition; but as soon as they had dispersed among the narrow streets, the garrison opened a deadly fire on them from the latticed windows and the roofs of the houses. They effected a retreat on Aboukir and Alexandria, after a very heavy loss of 285 killed and 482 wounded, General Wauchope and three officers being among the former, and General Meade and nineteen officers among the latter. The heads of the slain were fixed on stakes on each side of the road crossing the Elbeikia in Cairo.

Mehemet Ali, meanwhile, was conducting an expedition against the beys in Upper Egypt, and he had defeated them near Asiss, when he heard of the arrival of the British. In great alarm lest the beys should join them, especially as they were far north of his position, he immediately sent messengers to his rivals, promising to comply with all their demands if they should join in expelling the invaders; and this proposal being agreed to, both armies marched towards Cairo on opposite sides of the river.

To return to the unfortunate British expedition. The possession of Rosetta being deemed indispensable, Brigadier-Generals Sir William Stewart and Oswald were despatched thither with 2500 men. For thirteen days a cannonade of the town was continued without effect; and on the 20th of April, news having come in from the advanced guard at Hamád of large
reinforcements to the besieged, General Stewart was compelled to retreat; and a dragoon was despatched to Lieutenant-colonel Macleod, commanding at Hamād, with orders to fall back. The messenger, however, was unable to penetrate to the spot; and the advanced guard, consisting of a detachment of the 31st, two companies of the 78th, one of the 35th, and De Rolli's regiment, with a picquet of dragoons, the whole mustering 733 men, was surrounded, and, after a gallant resistance, the supply trains and some of their ammunition, became prisoners of war. General Stewart regained Alexandria with the remainder of his force, having lost, in killed, wounded and missing, nearly 900 men. Some hundreds of British heads were now exposed on stakes in Cairo, and the prisoners were marched between these mutilated remains of their countrymen. The boys became divided in their wishes, one-party being desirous of co-operating with the British, the other with the pasha. These delays proved ruinous to their cause; and General Fraser, despairing of their assistance, evacuated Alexandria on the 14th of September. From that date to the spring of 1811 the boys from time to time relinquished certain of their demands; the pasha on his part granted them what before had been withheld; the province of the Fayum, and part of those of Gīsa and Beni-Suef, were ceded to Shāhīn; and a great portion of the Sa'id, on the condition of paying the land-tax, to the others. Many of them took up their abode in Cairo, but the consequences of this treason, this force of the pasha, was felt by them in forces in battle and once gained a signal victory. Early in the year 1811, the preparations for an expedition against the Wahhābis in Arabia being complete, all the Mameluk bays then in Cairo were invited to the ceremony of investing Mehemet Ali's favourite son, Tūsūn, with a pelisse and the command of the army. As on the former occasion, the unfortunate Mamelukes fell into the snare. On the 1st of March, Shāhīn Bey and the other chieftains (one only excepted) repaired with their retinues to the citadel, and were courteously received by the pasha. Having taken coffee, they formed in procession, and, preceded and followed by the pasha's troops, slowly descended the steep and narrow road leading to the great gate of the citadel; but as soon as the Mamelukes arrived at the gate it was suddenly closed before them. The last of those to leave before the gate was shut were Albanians under Shāhī Kush. To these troops their chief now made known the pasha's orders to massacre all the Mamelukes within the citadel; therefore, having returned by another way, they gained the summits of the walls and houses that hem in the road in which the Mamelukes were confined, and some stationed themselves upon the eminences of the rock through which that road is partly cut. Thus securely placed, they began a heavy fire on their victims; and immediately the troops who closed the procession, and who had the advantage of higher ground, followed their example. Of the betrayed chieftains, many were laid low in a few moments; some, dismounting, and throwing off their outer robes, vainly sought, sword in hand, to return, and escape by some other gate. The few who regained the summit of the citadel experienced the same fate as the rest, for no quarter was given. Four hundred and seventy Mamelukes entered the citadel; and of these very few, if any, escaped. One of these is said to have been a bey. According to some, he leapt his horse from the ramparts, and alighted uninjured, though the horse was killed by the fall; others say that he was prevented from joining his comrades, and discovered the treachery while waiting without the gate. He fled and made his way to Syria. This massacre was the signal for an indiscriminate slaughter of the Mamelukes throughout Egypt, orders to this effect being transmitted to every governor; and in Cairo itself the houses of the boys were given over to the soldiery. During the two following days the pasha and his son Tūsūn rode about the streets and tried to stop the atrocities; but order was not restored until 500 houses had been completely pillaged. The heads of the boys were sent to Constantinople. A remnant of the Mamelukes fled to Nubia, and a tranquillity was restored to Egypt to which it had long been accustomed. In the year following the massacre the unfortunate exiles were attacked by Ibrahim Pasha, the eldest son of Mehemet Ali, in the fortified town of Ibrin, in Nubia. Here the want of provisions forced them to evacuate the place; a few who surrendered were beheaded, and the rest went farther south and built the town of New Dongola (correctly Dunkulah), where the venerable Ibrahim Bey died in 1816, at the age of eighty. As their numbers thinned, they endeavoured to maintain their little power by training some hundreds of blacks; but again, on the approach of Lamail, another son of the pasha of Egypt sent with an army in 1820 to subdue Nubia and Sennār, some returned to Egypt and settled in Cairo, while the rest, amounting to about 100 persons, fled in dispersed parties to the countries adjacent to Sennār.

3. Modern History.

(1) Rule of Mehemet Ali.—Mehemet Ali was now undisputed master of Egypt, and his efforts henceforth were directed primarily to the maintenance of his practical independence. The suzerainty of the sultan he acknowledged, and at the reiterated commands of the Forte he despatched in 1811 an army of 8000 men, including 2000 horse, under the command of his son Tūsūn, a youth of sixteen, against the Wahhābis (q.v.). After a successful junction with the British at Wadi el-Natrun, this force was again defeated, this time at the Battle of Judeida, near Safra, and retreated to Yembo' (Yamb). In the following year Tūsūn, having received reinforcements, again assumed the offensive, and captured Medina after a prolonged siege. He next took Jidda and Mecca, defeating the Wahhābis beyond the latter place and capturing their general. But some mishaps followed, and Mehemet Ali, who had determined to conduct the war in person, left Egypt for that purpose in the spring of 1813. In Arabia he encountered serious obstacles from the nature of the country and the harassing mode of warfare adopted by his adversaries. His arms met with various fortunes; but on the whole his forces proved superior to those of the enemy. He deposed and exiled the sharif of Mecca, and after the death of the Wahhābi leader Saud II. he concluded in 1815 a treaty with Saud's son and successor, Abdullah. Hearing of the escape of Napoleon from Elbe— and fearing danger to Egypt from the planns of France or Great Britain—Mehemet Ali returned to Cairo with the help of Kosseir and Ken. He reached the capital on the day of the battle of Waterloo. His return was hastened by reports that the Turks, whose cause he was upholding in Arabia, were treacherously planning an invasion of Egypt.

During Mehemet Ali's absence in Arabia his representative at Cairo had completed the confiscation, begun in 1806, of almost all the lands belonging to private individuals, who were forced to accept instead inadequate pensions. By this revolutionary method of land "nationalization" Mehemet Ali became proprietor of nearly all the soil of Egypt, an iniquitous measure against which the Egyptians had no remedy. The attempt which in this year (1815) the pasha made to reorganize his troops on European lines led, however, to a formidable mutiny in Cairo. Mehemet Ali's life was endangered, and he sought refuge by night in the citadel, while the soldiery committed many acts of plunder. The revolt was reduced by presents to the chiefs of the insurgents, and Mehemet Ali ordered that the sufferers by the disturbances should receive compensation from the treasury. The project of the Nisām Čedid (New System), as the European system was called, was, in consequence of this mutiny, abandoned for a time. Tūsūn returned to Egypt on hearing of the military revolt at Cairo, but died in 1816 at the early age of twenty. Mehemet Ali, dissatisfied with the treaty concluded with the Wahhābis, and with the non-fulfilment of certain of its clauses, determined to send another army to Arabia, and to include in it the soldiers who had recently proved unruly. This expedition, under his eldest son Ibrahim Pasha, left in the autumn of 1816. The war was long and arduous, but in 1818 Ibrahim captured the Wahhābi capital of Deraīya. Abdullah, their chief, was made prisoner,
and with his treasurer and secretary was sent to Constantinople, where, in spite of Ibrahim's promise of safety, and of Mehemet Ali's intercession in their favour, they were put to death. At the end of 1820, Ibrahim turned to Cairo, having subdued all present opposition in Arabia.

Meanwhile the pasha had turned his attention to the improvement of the manufactures of Egypt, and engaged very largely in commerce. He created for himself a monopoly in the chief products of the country, to the further impoverishment of the people, and set up and kept going for years factories which never paid. But some of his projects were sound. The work of digging (1819–1820) the new canal of Alexandria, called the Mahmudiya (after the reigning sultan of Turkey), was specially important. The old canal had long fallen into decay, and the necessity of a safe channel between Alexandria and the Nile was much felt. Such was the object of the canal then excavated, and it answered its purpose; but the sacrifice of life was enormous (fully 20,000 workmen perished), and the labour of the unhappy fellahin was forced. Another notable fact in the economic progress of the country was the development of the cultivation of cotton in the Delta in 1822 and onwards. The cotton grown had been brought from the Sudan by Maho Bey, and the organization of the new industry—from which in a few years Mehemet Ali was enabled to extract considerable revenues—was entrusted to a Frenchman named Jumel.

In 1820 Mehemet Ali ordered the conquest of the eastern Sudan to be undertaken. He first sent an expedition westward to the south, which captured and annexed the oasis of Siwa. Among the pasha's reasons for wishing to extend his rule southward were the desire to capture the valuable caravan trade then going towards the Red Sea, and to secure the rich gold mines which he believed to exist in Sennar. He also saw in the campaign a means of getting rid of the disaffected troops, and of obtaining a sufficient number of captives to form the nucleus of the new army. The forces destined for this service were led by Farnoul, then the youngest son of Mehemet Ali; they consisted of between 4000 and 5000 men, Turks and Arabs, and left Cairo in July 1820. Nubia at once submitted, the Shagia Arabs immediately beyond the province of Dongola were worsted, the remnant of the Mamelukes dispersed, and Sennar reduced without a battle. Mahammed Bey, the defterdar, with another force of about the same strength, was then sent by Mehemet Ali against Kordofan with a like result, but without a hard-fought engagement. In October 1822 Farnoul was, with his return, burnt to death by the makh (king) of Shendi; and the defterdar, a man infamous for his cruelty, assumed the command of those provinces, and exacted terrible retribution from the innocent inhabitants. Khartum was founded at this time, and in the following years the rule of the Egyptians was largely extended and control obtained of the Red Sea ports of Suakin and Massawa (see Sudan: History).

In 1824 a native rebellion of a religious character broke out in Upper Egypt headed by one Ahmed, an inhabitant of Es-Salimiyah, a village situated a few miles above Thebes. He proclaimed himself a prophet, and was soon followed by between 20,000 and 30,000 insurgents, mostly peasants, but some of them deserters from the "Nizam Gedid," for that force was yet in a half-organized state, and in part declared for the impostor. The insurrection was crushed by Mehemet Ali, and about one-fourth of Ahmed's followers perished, but he himself escaped and was never after heard of. Few of these unfortunate possessed any other weapon than the long staff (seebud) of the Egyptian peasant; still they offered an obstinate resistance, and the combat in which they were defeated resembled a massacre. This movement was the last internal attempt to destroy the pasha's authority.

The fellahin, a patient, long-suffering race save when stirred by religious fanaticism, submitted to the kurbash, and were freely used by the Turkish and Bashir Basuk tax-gatherers employed by Mehemet Ali to enforce his system of taxation, monopolies, corvée and conscription. Under this régime the resources of the country were impoverished, while the finances fell into complete and incomprehensible chaos.

A vivid picture of the condition to which Egypt was reduced is painted in the report drawn up in 1836 by the British consul-general in Egypt, Colonel Cambre.

"The government (he wrote), possessing itself of the necessaries of life at prices fixed by itself, disposes of them at arbitrary prices. The fellah is thus deprived of his harvest and falls into arrears with his taxes, and is further molested and destitute to force him to pay his debts. This leads to deterioration of agriculture and the depression of production. The pasha having imposed high taxes has caused the high prices of the necessaries of life. It would be difficult for a foreigner now coming to Egypt to form a just idea of the actual state of the country as compared with its former state. In regard to the general rise in prices, all the ground cultivated under the Mamelukes is employed for produce of wheat, barley, beans, &c., instead of being leased to the immense quantities. The people reared fowls, sheep, goats, &c., and the prices were one-sixth, or even one-tenth, of those at present. This continued until Mehemet Ali became viceroy in 1805. From that period until the establishment of monopolies prices have gradually increased; but the great increase has chiefly taken place since 1824, when the pasha established his regular army, navy and factories."

The conclusion in 1836 of a commercial treaty with Turkey, negotiated by Sir Henry Bulwer (Lord Dalling), struck a death-blow to the system of monopolies, though the application of the treaty to Egypt was delayed for some years. The picture of Egypt under Mehemet Ali is nevertheless not complete without regard being had to the beneficent side of his rule. Public order was rendered perfect; the Nile and the highways were secure from robbers; the officers and soldiers of the army were won over to peaceful pursuits, and genuine efforts were made to promote education and the study of medicine. To European merchants, on whom he was dependent for the sale of his exports, Mehemet Ali showed much favour, and under his influence the port of Alexandria again rose into importance. It was also under Mehemet Ali's encouragement that the overland transit of goods from Europe to India via Egypt was resumed.

Mehemet Ali was fully conscious that the enterprise which he had so laboriously built up might at any time have to be defended by force of arms against his master Sultan Mahmoud II., whose whole policy had been directed to curbing the power of his too ambitious vassals, and who was under the influence of the personal enemies of the pasha of Egypt, notably of Khosrev, the grand vizier, who had never forgiven his humiliation in Egypt in 1803. Mahmoud also was already planning reforms borrowed from the West, and Mehemet Ali, who had had plenty of opportunity of observing the superiority of European methods of warfare, was determined to anticipate the sultan in the creation of a fleet and an army on modern lines, partly as a measure of precaution, partly as an instrument for the realization of yet wider schemes of ambition. Before the outbreak of the War of Greek Independence in 1821 he had already expended much time and energy in organizing a fleet and in training, under the supervision of French instructors, native officers and artificers; though it was not till 1829 that the opening of a dockyard and arsenal at Alexandria enabled him to build and equip his own vessels. By 1823, moreover, he had succeeded in carrying out the reorganization of his army on European lines, the turbulent Turkish and Albanian elements being replaced by negroes and fellahin.1 His foresight was rewarded by the invitation of the sultan to help him in the task of subduing the Greek insurgents, offering as reward the pashalik of the Morea and of Syria. Mehemet Ali had already in 1821, as we have seen, been elected governor of Crete, which he had occupied with a small Egyptian force. In the autumn of 1824 a fleet of sixty Egyptian war-ships carrying a large force of disciplined troops concentrated in Suda Bay, and, in the following March, Ibrahim as commander-in-chief landed in the Morea. But for the action of European powers the intervention of Mehemet Ali would have

1 The work was carried out under the supervision of the Frenchman Colonel Seve, who had turned Mohammedan and was known in Islam as Suleiman Pasha. The effectiveness of the new force was first tried in the suppression of a revolt of the Albanians in Cairo (1821) by six disciplined Sudanese regiments; the after which Mehemet Ali was no more troubled with military uneasy.
been decisive. His naval superiority wrested from the Greeks the command of the sea, on which the fate of the insurrection ultimately depended, while on land the Greek irregular bands were everywhere routed by Ibrahim's disciplined troops. The history of the events that led up to the battle of Navarino and the liberation of Greece is told elsewhere (see NAVARINO and GREEK INDEPENDENCE, WAR 97); the withdrawal of the Egyptians from the Morea was ultimately due to the action of Admiral Lord Cochrane. By the spring of 1828, the pasha, by no means sorry to have a reasonable excuse, by a threat of bombardment, to sign a convention undertaking to recall Ibrahim and his army.

Before the final establishment of the new kingdom of Greece, the Eastern question had late in 1831 entered into a new and more perilous phase, owing to the revolt of Mehemet Ali against the sultan on pretext of chastising the ex-slave Abdullah, pasha of Acre, for refusing to send back Egyptian fugitives from the effects of Mehemet Ali's "reforms." The true reason was the refusal of Sultan Mahmud to hand over Syria according to agreement, and Mehemet Ali's determination to obtain at all hazards what had been from time immemorial an object of ambition to the rulers of Egypt. For ten years from this date the relations of sultan and pasha remained in the forefront of the questions which agitated the diplomatic world. It was not only the very existence of the Ottoman empire that seemed to be at stake, but Egypt itself had become more than ever an object of attention, to British statesmen especially, and in the issue of the struggle were involved the interests of Great Britain in the two routes to India by the Isthmus of Suez and the valley of the Euphrates. The diplomatic and military history of this period will be found sketched in the article on Mehemet Ali. Here it will suffice to say that the victorious career of Ibrahim, who once more commanded in his father's name, beginning with the storming of Acre on the 27th of May 1832, and culminating in the rout and capture of Reshid Pasha at Konia on the 21st of December, was arrested by the intervention of Russia. As the result of endless discussions between the representatives of the powers, the Porte and the pasha, the convention of Kutaya was signed on the 14th of May 1833, by which the sultan agreed to bestow on Mehemet Ali the pashaliks of Syria, Damascus, Alepo and Itcheli, together with the district of Adana. The announcement of the pasha's appointment had already been made in the usual way in the annual firman issued on the 3rd of May. Adana, reserved for the moment, was bestowed on Ibrahim under the style of muhassis, or collector of the crown revenues, a few days later.

Mehemet Ali now ruled over a virtually independent empire, subject only to a moderate tribute, stretching from the Sudan to the Taurus Mountains. But though he was hailed, especially in France, as the pioneer of European civilization in the East, the unsound foundations of his authority were not long in revealing themselves. Scarcely a year from the signing of the convention of Kutaya the application by Ibrahim of Egyptian methods of government, notably of the monopolies and conscription, had driven Syrians, Druses and Arabs, who had welcomed him as a deliverer, into revolt. The unrest was suppressed by Mehemet Ali in person, and the Syrians were terrorized and disarmed. But their discontent encouraged Sultan Mahmud to hope for revenge, and a renewal of the conflict was only staved off by the anxious efforts of the powers. At last, in the spring of 1839, the sultan ordered his army, concentrated under Reshid in the Upper district of Bir on the Euphrates, to advance over the Syrian frontier. Ibrahim, seeing his flank menaced, attacked it at Nezib on the 24th of June. Once more the Ottomans were utterly routed. Six days later, before the news reached Constantinople, Mahmud died.

Once more the Ottoman empire lay at the feet of Mehemet Ali; but the powers were now more prepared to meet a contingency which had been long foreseen. Their intervention was prompt; and the dispute was referred from the concert and encouraged Mehemet Ali to resist, only to his obtaining less favourable terms. (See MEHEMET ALL.)

The end was reached early in 1841. New firman was issued which confined the pasha's authority to Egypt, the Sinai peninsula and certain places on the Arabian side of the Red Sea, and to the Sudan. The most important of these documents are dated the 15th of February 1841. The government of the pashalik of Egypt was made hereditary in the family of Mehemet Ali. A map showing the boundaries of Egypt accompanied the firman granting Mehemet Ali the pashalik, a duplicate copy being retained by the Porte. The Egyptian copy is supposed to have been lost in a fire which destroyed a great part of the Egyptian archives. The Turkish copy has never been produced and its existence now appears doubtful. The point is of importance, as in 1802 and again in 1806 boundary disputes arose between Turkey and Egypt (see below). Various restrictions were laid upon Mehemet Ali, emphasizing his position of vassalage. He was forbidden to maintain a fleet, and his army was not to exceed 18,000 men. The pasha was no longer a figure in European politics, but he continued to occupy himself with his improvements, real or imaginary, in Egypt. The condition of the country was deplorable; in 1842 a murrain of cattle was followed by a destructive Nile flood; in 1843 there was a plague of locusts, whole villages were depopulated. Meantime the uttermost farting was wrung from the wretched fellahin, while they were forced to the building of magnificent public works by unpaid labour. In 1844-1845 there was some improvement in the condition of the country as a result of financial reforms the pasha was compelled to execute. Mehemet Ali, who had been the honorary rank of grand vizier in 1842, paid a visit to Stamboul in 1846, where he became reconciled to his old enemy Khosrev Pasha, whom he had not seen since he spared his life at Cairo in 1803. In 1847 Mehemet Ali laid the foundation stone of the great barrage across the Nile at the beginning of the Delta. He was barely persuaded from ordering the barrage to be built with stone from the pyramids! Towards the end of 1847 the aged pasha's mind began to give way, and by the following June he was no longer capable of administering the government. In September 1848 Ibrahim was acknowledged by the Porte as ruler of the pashalik, but he died in the November 1

following. - Mehemet Ali survived another eight months, dying on the 2nd of August 1849, aged eighty. He had done a great work in Egypt; the most permanent being the weakening of the tie binding the country to Turkey, the starting of the great cotton industry, the recognition of the advantages of European science, and the conquest of the Sudan.

On Ibrahim's death in November 1848 the government of Egypt fell to his nephew Abbas I. (q.v.), the son of Yusua. Abbas put an end to the system of commercial monopolies, and during his reign the railway from Alexandria to Cairo was begun at the instigation of the British government. Opposed to European ways, Abbas lived in great seclusion, and after a reign of less than six years he was murdered (July 1854) by two of his slaves. He was succeeded by his uncle Said Pasha, the favourite son of Mehemet Ali, who lacked the strength of mind or physical health needed to execute the benefactive projects which he conceived. His endeavour, for instance, to put a stop to the slave raiding which devastated the Sudan provinces was wholly ineffectual. He had a genuine regard for the welfare of the fellahin, and a land law of 1858 secured to them an acknowledgment of freehold as against the crown. The pasha was much under French influence, and in 1856 was induced to grant Ferdinand de Lesseps a concession for the construction of the Suez Canal. Lord Palmerston was opposed to this, and the Egyptian position was now raised to the level of the concession by the Porte for two years. To the British Said also made concessions—one to the Eastern Telegraph Company, and another (1854) allowing the establishment of the Bank of Egypt. He also began the national debt by borrowing £3,325,000 from Messrs Fröhling & Göschen, the actual amount received by the pasha being £2,640,000. In January 1863 Said Pasha died and was succeeded by his nephew Ismail, a son of Ibrahim Pasha.

The reign of Ismail (q.v.), from 1863 to 1879, was for a while hailed as introducing a new era into modern Egypt. In spite of his vast schemes of reform and the lavish of his Europeanizing innovations, his oriental extravagance led to bankruptcy, and his reign is historically important simply for its compelling European intervention in the internal affairs of Egypt. Yet in its earlier years much was done which seemed likely to give Ismail a more important place in history. In 1866 he was granted by the sultan a firman—obtained on condition of the increase of the tribute from £376,000 to £210,000—by which the succession to the throne of Egypt was made to descend "to the eldest of thy male children and in the same manner to the eldest sons of thy successors," instead of, after Turkish law, to the eldest male of the family. In the following year another firman bestowed upon him the khedive's title in lieu of that of sultan, borne by Mehemet Ali and his immediate successors. In 1873 a further firman placed the khedive in many respects in the position of an independent sovereign. Ismail re-established and improved the administrative system organized by Mehemet Ali, and which had fallen into decay under Abbas's indolent rule; he caused a thorough remodelling of the customs system, which was in an anarchic state, to be made by English officials; in 1865 he established the Egyptian post office; he reorganized the military schools of his grandfather, and gave some support to the cause of education. Railways, telegraphs, lighthouses, the harbour works at Suez, the breakwater at Alexandria, were carried out by some of the best contractors of Europe. Most important of all, the Suez Canal was opened in 1869. But the funds required for these public works, as well as the actual labour, were remorselessly extorted from a poverty-stricken population.

A striking picture of the condition of the people at this period is given by Lady Duff Gordon in Last Letters from Egypt. Writing in 1863, she describes the misery of the position created by the new tax. Every beast, camel, cow, sheep, donkey and horse is made to pay. The fellahin can no longer eat bread; they are driven to work for wages with water and bread, and pay the same tax. The taxation makes life almost impossible; a tax on every crop, on every animal first, and again when it is sold in the market; on every man, on charcoal, on butter, on salt. . . . The people in Upper Egypt are running away by wholesale, utterly unable to pay the new taxes and do the work exacted. Even here (Cairo) the beggars for the year's taxes are everywhere."

In the years that followed the condition of things grew worse. Thousands of lives were lost and large sums expended in extending Ismail's dominions in the Sudan (q.v.) and in futile conflicts with Abyssinia. In 1875 the impoverishment of the fellah had reached such a point that the ordinary resources of the country no longer sufficed for the most urgent necessities of administration; and the khedive Ismail, having repeatedly taken faith with his creditors, could not raise new loans on the European market. The taxes were habitually collected many months in advance, and the colossal floating debt was increasing rapidly. In these circumstances Ismail had to realize his remaining assets, and among them sold 776,605 Suez Canal shares to the British government for £3,976,381 (see BRACONSFIELD). This comparatively small financial operation brought about the long-delayed crisis and paved the way for the future prosperity of Egypt, for it induced the British government to inquire more carefully into the financial condition of the country. In December 1875 Mr Stephen Cave, M.P., and Colonel (afterwards Sir John) Stokes, R.E., were sent to Egypt to inquire into the financial situation; and Mr Cave's report, made public in April 1876, showed that under the existing administration national bankruptcy was inevitable. Other commissions of inquiry followed, and each one brought Ismail more under European control. The establishment of 48 new provincial tribunals in 1876, in place of the system of consular jurisdiction in civil actions, made some of the courts of justice international. The Caïsso de la Dette, instituted in May 1876 as a result of the Cave mission, led to international control over a large portion of the revenue. Next came (in November 1876) the mission of Mr (afterwards Lord) Goschen and M. Joubert on behalf of the British and French bondholders, one result being the establishment of Dual Control, i.e. an English official to superintend the revenue and a French official the expenditure of the country. Another result was the internationalization of the railways and the port of Alexandria. Then came (May 1878) a commission of inquiry of which the principal members were Sir Rivers Wilson, Major Evelyn Baring (afterwards Lord Cromer) and M.M. Kremer-Baravelli and de Blignières. One result of that inquiry was the extension of international control to the enormous property of the khedive. Dual Control, of which Ismail made a virtue of necessity and accepted, in September 1878, in lieu of the Dual Control, a constitutional ministry, under the presidency of Nubar Pasha (q.v.), with Rivers Wilson as minister of finance and de Blignières as minister of public works. Professing to be quite satisfied with this arrangement, he pompously announced that Egypt was no longer in Africa, but a part of Europe; but before seven months had passed he found his constitutional position intolerable, got rid of his irksome cabinet by means of a secretly-organized military riot in Cairo, and reverted to his old autocratic methods of government. England and France could hardly sit still under this fact, and decided to administer chastisement by the hand of the suzerain power, which was delighted to have an opportunity of asserting its authority. On the 26th of June 1879 Ismail suddenly received from the sultan a curt telegram, addressed to him as ex-khedive of Egypt, informing him that his son Tewfik was appointed his successor. Taken unawares, he made no attempt at resistance, and Tewfik was at once proclaimed khedive.

After a short period of inaction, when it seemed as if the change might be for the worse, England and France summoned up courage to look the situation boldly in the face, and, in November 1879, re-established the Dual Control in the persons of Major Baring and M. de Blignières. For two years the Dual Control governed Egypt, and initiated the work of progress begun by the French residents. 1

1 Part of this money was devoted to an expedition sent against Abyssinia in 1876 to avenge losses sustained in the previous year. The new campaign was, however, equally unsuccessful.
that England was to continue alone. Its essential defect was what might be called insecurity of tenure. Without any efficient means of self-protection and coercion at its disposal, it had to interfere with the power, privileges and perquisites of a class which had long misgoverned the country. This class, so far as its civilian members were concerned, was not very formidable, because these were not likely to go beyond the bounds of intrigue and passive resistance; but it contained a military element who had more courage, and who had learned their power when Ismail employed them for overturning his constitutional ministry. Among the mutinous soldiers on that occasion was a young captain calling himself Abdullah, or Arabi, the Egyptian. He was not a man of exceptional intelligence or remarkable powers of organization, but he was a fluent speaker, and could exercise some influence over the masses by a rude kind of native eloquence. Behind him were a group of men, much abler than himself, who put him forward as the figurehead of a party professing to aim at protecting the Egyptians from the grasping tyranny of their Turkish and European oppressors. The movement began among the Arab officers, who complained of the prejudice shown to the officers of Turkish origin; it then expanded into an attack on the privileged position and predominant influence of foreigners, many of whom, it must be confessed, were of a by no means respectable type; finally, it was directed against all Christians, foreign and native. 

The government, being too weak to suppress the agitation and disorder, had to make concessions, and each concession produced fresh demands. Arabi was first promoted, then made under-secretary for war, and ultimately a member of the cabinet. The danger of a serious rising brought the British and French fleets in May 1882 to Alexandria, and after a massacre (11th of June) which had been perpetrated by the Arab mob in that city, the British admiral bombarded the forts (11th of July 1882). The leaders of the national movement prepared to resist further aggression by force. A conference of ambassadors was held in Constantinople, and the sultan was invited to quell the revolt, but he hesitated to employ his troops against Musulmans who were professing merely to oppose Christian aggression.

(g) Egypt occupied by the British.—At last the British government determined to employ armed force, and invited France to co-operate. The French government declined, and a similar invitation to Italy met with a similar refusal. England therefore, having to act alone, landed troops at Ismailia under Sir Garnet Wolseley, and suppressed the revolt by the battle of Tell-el-Kebir on the 13th of September 1882. After no embargoes were placed in Alexandria, Lord Granville explained in a circular to the powers, the position of England in Egypt imposed on her the duty of giving advice with the object of securing that the order of things to be established shall be of a satisfactory character and possess the elements of stability and progress. But there was no general solution, which would increase unnecessarily the responsibilities of the protecting power and necessitate the indefinite prolongation of the military occupation. So far, therefore, as the British government had a definite policy in Egypt, it was a politique de replage. Even this policy was not strictly adhered to. Mr Gladstone's cabinet was as unstable as the public opinion it sought to conciliate. It had its hot fits and its cold fits, and it gave orders now to advance and now to retreat. In the long run circumstances proved too strong for it, and it had to undertake a great deal more than it originally intended. Each little change in the administration engendered a multitude of others, so that the modest attempts at reform were found to be like the letting out of water. A tiny rill gradually became a boisterous stream, and the boisterous stream grew into a great river, which spread to all sections of the administration and ended by inundating the whole country.

The Sudan question.

The laborious task of putting these general indications into a practical shape fell to Sir Evelyn Baring (Lord Cromer), who arrived as consul-general and diplomatic agent, in succession to Sir Edward Malet, in January 1884. At that moment the situation was singularly like that which had existed on two previous occasions: firstly, when Ismail was deposed; and secondly, when the Dual Control had undermined the existing authority without having any power to enforce its own. For the third time in little more than three years the existing authority had been destroyed and a new one had to be created. But there was one essential difference: the power that had now to reorganize itself possessed by its authority the army of organization of a support sufficient to command respect. Without that support Sir Evelyn Baring could have done little or nothing; with it he did perhaps more than any other single man could have done. His method may be illustrated by an old story long current in Cairo. Mehemet Ali was said to have appointed as mudir ez governor in a turbulent district a young and inexperienced Turk, who asked, "But how am I to govern these people?" "Listen," replied the pasha, "buy the biggest and heaviest kurbash you can find; hang it up in the centre of the mudirlik, well within your reach, and you will very seldom require to use it." The British army of occupation was Sir Evelyn's kurbash; it was well within his reach, as all the world knew, and its simple presence sufficed to prevent disorder and enforce obedience.

He had one other advantage over previous English reformers in Egypt: his position towards France was more independent. The Dual Control had been abolished by a khedival decree of 18th January 1883, and replaced by an English financial adviser. France naturally objected; but having refused to co-operate with England in suppressing the revolt, she could not reasonably complain that her offer of co-operation in the work of reorganization was declined. But though Dual Control was at an end, the Caisse de la Dette remained, and this body was to prove a constant clog on the financial measures of the Egyptian government.

At first the intention of the British government was simply to restore the power of the khedive, to keep his highness for some time in the right path by friendly advice, and to withdraw the British troops as soon as possible. As the Policy of evacuation. Lord Granville explained in a circular to the powers, the duty of giving advice with the object of securing that the order of things to be established shall be of a satisfactory character and possess the elements of stability and progress. But there was no general solution, which would increase unnecessarily the responsibilities of the protecting power and necessitate the indefinite prolongation of the military occupation. So far, therefore, as the British government had a definite policy in Egypt, it was a politique de replage. Even this policy was not strictly adhered to. Mr Gladstone's cabinet was as unstable as the public opinion it sought to conciliate. It had its hot fits and its cold fits, and it gave orders now to advance and now to retreat. In the long run circumstances proved too strong for it, and it had to undertake a great deal more than it originally intended. Each little change in the administration engendered a multitude of others, so that the modest attempts at reform were found to be like the letting out of water. A tiny rill gradually became a boisterous stream, and the boisterous stream grew into a great river, which spread to all sections of the administration and ended by inundating the whole country.

The Sudan question.

The Sudan question. 

The Sudan question has been a thorn in the flesh of all the British governments that have succeeded each other in the Sudan. The Sudan was an integral part of the khedive's dominions, and caused, even in ordinary times, a deficit of
EGYPT

£2,000,000 to the Egyptian treasury. At that moment it was in a state of open rebellion, stirred up by a religious fanatic who proclaimed himself a mahdi of Islam. An army of 10,000 men under an English officer, Colonel William Hicks, formerly of the Bombay army, otherwise Hicks Pasha, had been sent to suppress the revolt, and had been annihilated in a great battle fought on the 9th of November 1883, near Obeid. The Egyptian government wished to make a new attempt to recover the lost province, and the idea was certainly very popular among the governing class, but Sir Evelyn Baring vetoed the project on the ground that Egypt had neither soldiers nor money to carry it out. In vain the khedive and his prime minister, Sherif Pasha, threatened to resign, and the latter actually carried out his threat. The British representative remained firm, and it was decided that the Sudan should be, for the moment at least, abandoned to its fate. Nubar, though as strongly opposed to the abandonment policy as Sherif, consented to take his place and accept somewhat reluctantly the new régime, which he defined as "the administration of Egypt under the government of Baring." By this time the Mahdi was master of the greater part of the Sudan, but Khartoum and some other fortified points still held out. The efforts made to extricate the garrisons, including the mission of General Gordon, the fall of Khartoum, and the Nile Expedition under Lord Wolseley, are described below separately in the section of this article dealing with the military operations. The practical result was that the khedive's authority was limited to the Nile valley north of Wadi Halfa.

With the internal difficulties Sir Evelyn Baring had been struggling bravely ever since his appointment, trying to evolve out of the ever-changing policy and contradictory orders of the British government some sort of coherent line of action, and to raise the administration to a higher standard. For two or three years it seemed doubtful whether he would succeed. All over Egypt there was much unrest, and the well-mean but not very successful efforts of the British to improve the state of things were making them very unpopular. The introduction of English officials and English influence into all the administrative departments was resented by the native officials, and the action of the irrigation officers in preventing the customary abuses of the distribution of water was resented by the great landowners, who had been, from time immemorial, in the habit of taking as much as they wanted, to the detriment of the fellahin. Even these latter, who gained most by the reforms, considered that they had good reason to complain, for the defeat of Arabi and the re-establishment of order had enabled the Christian money-lenders to return and insist on the payment of claims, which were supposed to have been extinguished by the rebellion. Worst of all, the government was shifting rapidly towards insolvency, being quite unable to fulfil its obligations to the bondholders and meet the expenses of administration. All departments were being starved, and even the salaries of poorly paid officials were in arrear. To free itself from its financial difficulties the government adopted a heroic remedy which only created fresh troubles. On the advice of Lord Northbrook, who was sent out to Cairo in September 1884, to examine the financial situation, certain revenues which should have been paid into the Caisse for the benefit of the bondholders were paid into the treasury for the ordinary needs of the administration. Immediately the powers protested against this in-fracion of the law of liquidation, and the Caisse applied for a writ to the Mixed Tribunals. In this way the heroic remedy failed, and to the internal difficulties were added international complications.

Fortunately for Egypt, the British government contrived to solve the international difficulty by timely concessions to the powers, and succeeded in negotiating the London Convention of March 1885, by which the Egyptian government was relieved from some of the most onerous stipulations of the law of liquidation, and was enabled to raise a loan of £9,000,000 for an annual payment of £135,000. After paying out of the capital the sums required for the indemnities due for the burning of Alexandria and the deficits of the years 1882 and 1883, it still had a million sterling, and boldly invested it in the improvement of irrigation. The investment proved most remunerative, and helped very materially to save the country from bankruptcy and internationalism. The danger of being again subjected to the evils of an international administration was very great, for the London Convention contained a stipulation to the effect that if Egypt could not pay her way at the end of two years, another international commission would be appointed.

To obviate this catastrophe the British reformers set to work more energetically. Already something in the way of retrenchment and reform had been accomplished. The public accounts had been put in order, and the abuses in the collection of the land tax removed. The constant drain of money and men for the Sudan had been stopped. A beginning had been made for creating a new army to replace the one that had been disbanded and to allow of a portion of the British garrison being withdrawn. In this work Sir Evelyn Wood had shown much sound judgment as well as great capacity for military organization, and had formed an efficient force out of very unpromising material (see the section above on the Egyptian Army). His colleague in the department of public works, Sir Colin Scott-Moncrieff, had been not less active. By mitigating the hardships of the corvée, and improving the irrigation system, on which the prosperity of the country mainly depends, he had conferred enormous benefits on the fellahin, and had laid the foundation of permanent prosperity equilibrium for the future. Not less active was Sir Edgar Vincent, the financial adviser, who kept a firm hold on the purse-strings and ruthlessly cut down expenditure in all departments except that of irrigation (see § Finance).

The activity of the British officials naturally produced a certain amount of discontent and resistance on the part of their Egyptian colleagues, and Lord Granville was obliged to declare very plainly that such resistance could not be tolerated. Writing (January 1884) to Sir Evelyn Baring, he said: "I should be made clear about the Egyptian Ministers and Governors of Provinces that the responsibility which for the time rests on England obliges H.M. Government to insist on the adoption of the policy which they recommend; and that it will be necessary that those Ministers and Governors who do not follow this course should cease to hold their offices." Nubar Pasha, who continued to be prime minister, resisted occasionally. What he bitterly objected to was direct interference in the provincial administration and the native tribunals, and he succeeded for a time in preventing such interference. Sir Benson Maxwell and Mr Clifford Lloyd, who had been sent out to reform the departments of justice and the interior, after coming into conflict with each other were both recalled, and the reforming activity was for a time restricted to the departments of war, public works and finance. Gradually the tension between natives and foreigners relaxed, and mutual confidence was established. Experience had evolved the working principle which was officially formulated at a much later period: "Our task is not to rule the Egyptians, but as far as possible to teach the Egyptians to rule themselves. . . . . . . European initiative suggests measures to be executed by Egyptian agency, while European supervision controls the manner in which they are carried out." If that principle had been firmly laid down and clearly understood at the beginning, a good deal of needless friction would have been avoided.

The international difficulty remained. The British position in Egypt was anomalous, and might easily give rise to international complications. The sultan might well protest against the military occupation of a portion of his empire by foreign troops. It was no secret that France was ready to give him diplomatic support, and other powers might adopt a similar attitude. Besides this, the British government was anxious to terminate the occupation as soon as possible. With a view to regularizing the situation and accelerating the evacuation, Sir Henry Drummond Wolff was sent to Constantinople in August 1885 on a special mission. On the 24th of October of that year he concluded a preliminary
Convention by which an Ottoman and a British high commissioner, acting in concert with the khedive, should reorganize the Egyptian army, tranquilize the Sudan by pacific means, and consider what changes might be necessary in the civil administration. When the two commissioners were assured of the security of the frontier and the good working and stability of the Egyptian government, they should present reports to their respective governments, and these should consult as to the conclusion of a convention regulating the withdrawal of the English troops. Mukhtar Pasha and Sir Henry Drummond Wolff were appointed commissioners, and their joint inquiry lasted till the end of 1886, when the former presented his report and the latter went home to report orally. The remaining stipulations of the preliminary convention were duly carried out. Sir Henry Drummond Wolff proceeded to Constantinople and signed on the 22nd of May 1887 the definitive convention, according to which the occupation should come to an end in three years, but England should have a right to prolong or renew it in the event of internal peace or external security being seriously threatened. The sultan authorised the signature of this convention, but under pressure of France and Russia he refused to ratify it. Technically, therefore, the preliminary convention still remains in force, and in reality the Ottoman commissioner continued to reside in Cairo till the close of 1898.

The steadily increasing prosperity of the country during the years 1885-1886 removed the danger of national bankruptcy and international interference, and induced the Egyptian government to widen the area of administrative reforms. In the provinces the local administration and the methods of dispensing justice were still scandalously unsatisfactory, and this was the field to which the British representative next directed his efforts. Here he met with unexpected opposition on the part of the prime minister, Nubar Pasha, and a conflict ensued which ended in Nubar’s retirement in January 1888. Nubar Pasha took his place, and remained in office till May 1891. During these three years the work of reform and the prosperity of the country made great progress. The new Egyptian army was so far improved that it gained successes over the forces of the Mahdi; the burden of the national debt was lightened by a successful conversion; the deâdâh was abolished; the land tax was reduced 30% in the poorest provinces, and in spirit, tax and other measures for lightening the public burdens, the budgetary surplus constantly increased; the quasi-judicial special commissions for brigandage, which were at once barbarous and inefficient, were abolished; the native tribunals were improved, and Mr. (afterwards Sir John) Scott, an Indian judge of great experience and sound judgment, was appointed judicial adviser to the khedive. This appointment was opposed by Nubar Pasha, and led to his resignation on the plea of ill-health. His successor, Mustafa Pasha Fehmi, continued the work and co-operated cordially with the English officials. The very necessary reform of the native tribunals was then taken seriously in hand. The existing procedure was simplified and accelerated; the working of the courts was greatly improved by a carefully organized system of inspection and control; the incompetent judges were eliminated and replaced by men of better education and higher moral character; and for the future supply of well-qualified judges, barristers, and law officials, an excellent school of law was established. Later on the reforming activity was extended to prisons, public health, and education, and has attained very satisfactory results.

In January 1892 the khedive Tewfik, who had always maintained cordial relations with Sir Evelyn Baring, died suddenly, and was succeeded by his son, Abbas Hilmi, a young man without political experience, who failed at first to understand the peculiar situation in which a khedive ruling under British protection is necessarily placed. Aspiring to liberate himself at once from foreign control, he summarily dismissed Mustafa Pasha Fehmi (15th January 1893), whom he considered too amenable to English influence, and appointed his place Fakhri Pasha, who was not a personage at the British Agency. Such an incident, which might have constituted a precedent for more important acts of a similar kind, could hardly be overlooked by the British representative. He had always maintained that what Egypt most required, and would require for many years to come, was an order of things which would render practically impossible any return to that personal system of government which had well-nigh ruined the country. In this view the British agent was warmly supported by Lord Rosebery, then secretary of state for foreign affairs. The young khedive was made therefore to understand that he must not make such changes in the administration without a previous agreement with the representative of the protecting power; and a compromise was effected by which Fakhri Pasha retired, and the post of premier was confined once more to Riaz. With this compromise the friction between the khedive and Sir Evelyn Baring, who had now become Lord Cromer, did not end. For some time Abbas Hilmi clung to his idea of liberating himself from all control, and secretly encouraged a nationalist and anti-British agitation in the native press; but he gradually came to perceive the folly, as well as the danger to himself, of such a course, and accordingly refrained from giving any overt occasion for complaint or protest. In like manner the relations between the British officials and their Egyptian colleagues gradually became more cordial, so that it was found possible at last to make a concession in the person of Sir Evelyn Baring’s retirement in the spring of 1894 on the recommendations of Mr. (afterwards Sir) Eldon Gorst, who had been appointed adviser to the ministry of the interior. Nubar Pasha, it is true, who succeeded Riaz as prime minister in April 1894, objected to some of Mr. Gorst’s recommendations, and in November 1895 resigned. He was succeeded by Mustafa Fehmi, who had always shown a conciliatory spirit, and who had been on that account, as above stated, summarily dismissed by the khedive in January 1893. After his resignation the Anglo-Egyptian condominium worked without serious friction.

The success of the Anglo-Egyptian condominium, and the consequent economic and financial prosperity of Egypt proper, rendered it possible, during 1896-1898, to recover Fashoda. From the Mahdists the Sudanese provinces (see Military Operations), and to delimit in that part of Africa, in accordance with Anglo-Egyptian interests, the respective spheres of influence of Great Britain and France. The arrangement was not effected without serious danger of a European conflict. Taking advantage of the temporary weakness of Egypt, the French government formed the project of seizing the Upper Nile valley and uniting her possessions in West Africa with those at the entrance to the Red Sea. With this object a small force under Major Marchand was sent from the French Congo into the Bahr-el-Ghazal, with orders to occupy Fashoda on the Nile; whilst a Franco-Abyssinian Expedition was despatched from the eastward, to join hands with Major Marchand. The small force from the French Congo reached its destination, and a body of Abyssinian troops, accompanied by French officers, appeared for a short time a little higher up the river; but the grand political scheme was frustrated by the victorious advance of an Anglo-Egyptian force under General Kitchener and the resolute attitude of the British government. Major Marchand had to retire from Fashoda, and as a concession to French susceptibilities he was allowed to retreat by the Abyssinian route. By an agreement signed by Lord Salisbury and the French ambassador on the 21st of March 1899, and appended to Art. IV. of the Anglo-French convention of June 14th, 1898, which dealt with the British and French spheres of influence in the region of the Niger, France was excluded from the basin of the Nile, and a line marking the respective spheres of influence of the two countries was drawn on the map from the northern frontier of the Congo Free State to the scarp south of the former Turkish province of Tripoli.

The administration of the Sudan (q.v.) was organized on the basis of an agreement between the British and Egyptian governments signed on the 10th of January 1899. According to that agreement the British and Egyptian flags are used together.
and the supreme military and civil command is vested in a governor-general, who is appointed by the khedive on the recommend-

ation of the British government, and who cannot be re-

moved without the British government's con-

sent. Neither consular jurisdiction, nor that of the mixed tribunals, was permitted, the Sudan being made absolutely free of the international fetters which bound Egypt. Sir Reginald Wingate, the airdar of the Egyptian army (in which post he succeeded Lord Kitchener at the close of 1890) was named governor-general, and in the work of regeneration of the country, the officials, British, Egyptian and Sudanese, had the cordial co-operation of the majority of the inhabitants.

The growing prosperity of Egypt in the opening years of the 20th century was very marked, and is reflected in the annual reports on the country supplied to the British foreign office by Lord Cromer. Thus, in 1901 he was able to declare that "...the foundations on which the well-being and material prosperity of a civilized community should rest have been laid. . . . The institution of slavery is virtually defunct. The corvee has been practically abolished. Law and order everywhere reign supreme. The curbash is no longer employed as an instrument of government." So little danger to internal peace was apprehended that during this year Arabi Pascha, who had been in exile in Ceylon since 1883, was permitted to return to Egypt. This happy condition had been brought about by the fiscal reform, which was accompanied by substantial relief to the taxpayers, the first place in the government's programme, and with the abolition of octroi duties in 1902 disappeared the last of the main defects in the fiscal system as existing at the time of the British occupation. In these conditions the machinery of government, despite its many imperfections and anomalies, worked smoothly. Land increased in value as irrigation schemes were completed, and European capital was relatively eager to find investment in the country. The bulk of the fellahin enjoyed a material prosperity to which they had been strangers for centuries. In the midst of this return of plenty Lord Cromer (in his report for 1903) sounded a note of warning:

"As regards moral progress (he wrote), all that can be said is that it must necessarily be slower than advancement is a material direction. I hope and believe, however, that some progress is being made. In any case the machinery which will admit of progress has been created. That the schools are only a beginning, that every possible facility and every encouragement are afforded for the Egyptians to advance along the path of moral improvement. More than this no government can do. It remains for the Egyptians to take advantage of the opportunities offered to them."

The facilities enjoyed by the British and Egyptian governments for securing the material if not the moral development of Egypt were greatly enlarged in 1904, as the result of the understanding then to come between France and Great Britain. The natural irritation in France arising from the British occupation of the Nile valley, and the non-fulfilment of the pledge to withdraw the British garrison from Egypt, which had grown less acute with the passing of years, flamed out afresh at the time of the Faheeba crisis, while the Anglo-Boer war of 1899-1902 led to another access of irritation against England. During 1903 a great change came over public opinion on both sides of the Channel, with the result that the statesmen of both countries were enabled to complete negotiations settling many points in dispute between the two nations. On the 8th of April 1904 a declaration was signed by the representatives of the British and of Great Britain, and it was virtually recognized the dominant position of France in Morocco and of Britain in Egypt. The chief provisions concerning Egypt were:

"His Britannic Majesty's government declare that they have no intention of altering the political status of Egypt."

"The Anglo-French agreement was the text of a proposed khedivial decree altering the relations between Egypt and the foreign bond-holders. With the consent of the powers this decree (promulgated on the 28th of November 1904) came into operation on the 1st of January 1905. The combined effect of the declaration and the khedivial decree was great. The first-named put an end to any anomalous situation and gave a practically valid sanction to the presence of British in Egypt, removing all ground for the reproach that Great Britain was not respecting its international obligations. In effect it was a European recognition that Britain was the protecting power in Egypt. It put a period to a question which had long embittered the relations between England and France, and locally it caused the cessation of the systematic opposition of the French agents in Cairo to everything tending to strengthen the British position—but however beneficial to Egypt the particular scheme opposed might be. Scarcely less important were the results of the khedivial decree. By it Egypt achieved in effect financial independence. The power of the Caisse de la Dette, which had virtually controlled the execution of the international agreements concerning the finances, was swept away, together with almost all the other financial letters binding Egypt. The Railway and Port of Alexandria Board ceased to exist. For the first time since 1875 Egypt was free to control her own revenue. In return she pledged the greater part of the land tax to the service of the debt. The functions of the Caisse were restricted to the receipt of the funds necessary for this service. It was entirely deprived of its former power to interfere in the machinery of government. Moreover, some £10,000,000, being accumulated surpluses in the hands of the Caisse after meeting the charges of the debt, were handed over to the Egyptian government. The Egyptian government was henceforth free to take full advantage of the financial prosperity of the country.

In one respect the Anglo-French agreement made no alteration—it left untouched the extra-territoriality enjoyed by Europeans in Egypt in virtue of the treaties with Turkey, i.e. under the system of Capitulations. One of the anomalies under that system had, it is true, been got rid of; for, as has been stated, consular jurisdiction in civil matters had been replaced in 1876 by that of the Mixed Tribunals. In criminal cases, however, foreign consuls still exercised jurisdiction, but the main evil of the Capitulations régime was the absence of any proper machinery for enacting laws applicable to the whole of the inhabitants of Egypt. No change could be made in any law applicable to Europeans without the unanimous consent of fifteen foreign powers—a state of affairs wholly incompatible with the condition of Egypt in the 20th century; "an oriental country which has assimilated a very considerable portion of European civilization and which is mainly governed by European methods." It was, however, far easier to acknowledge that the Capitulations régime was defective and had outlived its time than to devise a remedy and get all the nations interested to accept it. The solution favoured by Lord Cromer (vide Blue-books, Egypt No. 1 (1906), pp. 1-8, and Egypt No. 1 (1907), pp. 10-26) was the creation of a council—distinct from the native legislative assembly—composed of council and assembly of Europeans, which should have the power to pass legislation which when promulgated by the Egyptian government, with the assent of the British government, would bind all foreigners resident in Egypt. Every reservation for the benefit of British subjects should endure for the benefit of subjects of other powers. The jurisdiction exercised by consuls in civil and criminal affairs Lord Cromer proposed should cease pari passu with the provision by the Egyptian government, under the powers conferred by the treaty required to set up the new council, of courts having competence to deal with such matters, various safeguards being introduced to prevent injustice in criminal cases. As to civil cases the proposal was to make permanent the Mixed Tribunals, hitherto appointed for quinquennial periods (so that if not reappointed consular jurisdiction in civil cases would revive)."
While the removal of ancient jealousies among the European powers interested in Egypt helped to smooth the path pursued by the Egyptian administration under the guiding hand of Great Britain, the intrigues of the Turks and the danger of a revival of Moslem fanaticism threatened again in 1905-1906 to cloud the peace of the country. A party led by Kamel Pasha (1874-1906), a member of the cabinet, whose known sentiments were, according to theTurkish ambassador, the opposite of the Turkish policy, led the party, and the danger of a revival of Moslem fanaticism threatened again in 1905-1906 to cloud the peace of the country. A party led by Kamel Pasha (1874-1906), who held that Egypt was ready for self-government and which saw in the presence of the British a hindrance to the attainment of their ideal. This "national" party lent what weight it had to the pan-Islamic agitation which arose in the summer and autumn of 1905, regardless of the fact that a pan-Islamic triumph meant the re-assertion of direct Turkish rule in Egypt and the end of the liberty the Egyptians enjoyed. The pan-Islamic press, allowed full licence by the Cairo authorities, spread abroad rumours that the Egyptian government intended to construct fortifications in the Sinai peninsula with the design of menacing the railway, under construction by Turkey, from Damascus to Mecca. This baseless report led to what is known as the Taba incident (see below). This incident inflamed the minds of many Egyptians, and almost all the opposition elements in the country were united by the attempt: to produce a movement of enthusiasm, and consequent action, to support the incident and partly the cause. The inflammatory writing of the newspapers indicated, encouraged by many persons holding high positions both inside and outside Egypt, created, by every process of misrepresentation, an anti-Christian and anti-European feeling among the mass of the people. After more than a quarter of a century of just rule, i.e., since the accession of Tewfik, the tyranny of the Turkish system was apt to be forgotten, while the appeal to rally in support of their khalif found a response in the hearts of many Egyptians. The feeling entertained by large numbers even of the educated class of Egyptians was strikingly illustrated by the terms of an anonymous letter received by Lord Cromer in May 1906. The writer, probably a member of the Ulema class, addressing the British agent as the re-former of Egypt, said:—

"... He must be blind who sees not what the English have wrought in Egypt; the gates of justice stand open to the poor; the streams flow through the land and are not stopped by order of the strong; the poor man is lifted up and the rich man pulled down, the hand of the oppressor and the bribe is struck when stretched to do evil. Our eyes see these things, and we know from whom they come. ... While peace is in the land the spirit of Islam sleeps, but is it said, 'There must be war between English and Muslims'."—Abdul Hamid Khan."

If that be so a change must come. The words of the Imam are echoed in every heart, and every Moslem hears only the voice of the Faith. ..." Thus, the Khalif of Egypt, as Beyazed, cruel as Murad, or mad as Ibrahim, is the shadow of God, and every Moslem must leap up at his call. ... You will say, 'The Egyptian is more ungrateful than a dog, which remembers the hand that feeds it. He is foolish, and the madman who doth pluck the roof-tree of his house upon himself.' It may be so to worldly eyes, but in the time of danger to Islam, the Moslem turns away from the things of the world and thinks only for the service of his Faith, even though he looks in the face of death. ..."

To establish confidence in the minds of the Egyptian public that the authorities could maintain order and tranquillity, it was determined to increase permanently the strength of the British garrison. An incident occurred in June 1906 which illustrated the danger which might arise if anything happened to begre the idea that the protecting power had weakened its hold. While mounted infantry of the British army were marching from Cairo to Alexandria, five officers went (on the 13th of June) to the village of Denshawa to shoot pigeons. 1

An attack was made on the party by the villagers. 1

The officers were told by their guide that they might shoot, but the villagers had not given permission and were challenging the officers. On hearing of this two of the officers was in an angry state, and a premeditated attack was made on the officers; a gun seized from one of them went off and slightly injured four natives—one a woman. The attack had been preceded by a striking fire at a threshing floor, either accidentally caused (but not by the officers' shots) or as a signal for the assault. Captain S. C. Bull of the 6th Dragoons received serious injuries and died a few hours later, and two other officers were seriously injured. A number of persons were arrested and tried by a special tribunal created in 1895 to deal with the army of occupation. On the 27th of the same month, 23 of the ringleaders were sentenced to death, others received various terms of imprisonment, and seven were sentenced to fifty lashes. The executions and floggings were carried out the next day at the scene of the outrage and in the presence of some five hundred natives. The quieting effect that this drastic action might have had was marred by the fact that certain members of the British parliament called in question the justice of the sentences—passed unanimously by a court of which the best English and the best native judge were members. For a time there was considerable ferment in Egypt. The Anglo-Egyptian authorities received, however, the firm support of Sir Edward Grey, the foreign secretary in the liberal administration formed in December 1905. As far as responsible statesmen were concerned the change of government in Great Britain made no difference in the conduct of Egyptian affairs.

The Taba incident, to which reference has been made, arose in the beginning of 1906 over the claim of the sultan of Turkey to jurisdiction in the Sinai peninsula. The origin of the dispute dated back, however, to 1892, when Abbas Hilmi became khedive. Mehmet Ali and his successors up to and including Tewfik had not only administered the Sinai peninsula but certain posts on the Hejaz or Arabian side of the gulf of Akaba. The firman of investiture issued by the sultan on the occasion of the succession of Abbas differed, however, from the text of former firman, the intention being, apparently, to exclude Egypt from the administration of the Sinai peninsula. The British government intervened and after considerable pressure upon Turkey obtained a telegram (dated the 8th of April 1892) from the grand vizier in which it was declared that the status quo was maintained in the Sinai peninsula, but that the sultan resumed possession of the posts in the Hejaz heretofore garrisoned by Egypt. To this last course Great Britain raised no objection. As officially stated by the British government at the time, the eastern frontier of the Sinai peninsula was taken to be a line running in a south-easterly direction from Rafa, a place on the Mediterranean, east of El Ariah, to the head of the gulf of Akaba. The fort of Akaba and other posts farther east Egypt abandoned. So matters rested until in 1905 in consequence of lawlessness among the Bedouins of the peninsula a British official was appointed commander and inspector of the peninsula and certain administrative measures were taken. The report was spread by pan-Islamic agents that the intention of the Egyptian government was to construct fortifications on the frontier near Akaba, to which place the Turks were building a branch railway from the El Arish-Damascus line. In January 1906 the sultan complained to the British ambassador at Constantinople of Egyptian encroachments on Turkish territory, whereupon the khedive asked that the frontier should be delimited, a request which Turkey rejected. A small Egyptian force was then directed to occupy Taba, a port near Akaba but on the western side of the gulf. Before this force could reach Taba that place had been seized by the Turkish commandant at Akaba. A period of considerable tension ensued, the Turks removing the boundary posts at Rafa and sending strong reinforcements to the frontier. The British government intervened on behalf of the khedive and consistently maintained that the Rafa-Akaba line must be the frontier. In April a conference was held between the khedive and Mukhtar Pasha, the Ottoman commissioner. It then appeared that Turkey was unwilling to recognize the British interpretation of the telegram of the 8th of April 1892. Turkey claimed that the peninsula of Sinai consisted

1 On the 8th of January 1906, the anniversary of the khedive's accession, the whole of the Denshawa prisoners were pardoned and released. For the Denshawa incident see the British parliamentary papers, Egypt No. 3 and Egypt No. 4 of 1906.
only of the territory south of a straight line from Akaba to Suez, and that Egyptian territory north of that line was traced from Rafa to Suez. As a compromise Mukhtar Pasha suggested as the frontier a line drawn direct from Rafa to Ras Mahommmed (the northernmost point of the Sinai peninsula), which would have left the whole of the gulf of Akaba to the south of the line. In other words the claim of the Porte was, to quote Lord Cromer:—

"to carry the Turkish frontier and strategic railways to Suez on the banks of the canal; or that if the Ras Mahommmed line were adopted the frontier would not be advanced to the neighbourhood of Nefli, i.e. within easy striking distance of Egypt, and that ... the gulf of Akaba ... would practically become a mere escarpment in the possession of Turkey and a standing menace to the security of the trade route to the East."

Such proposals could not be entertained by Great Britain, and as the sultan remained obstinate the British ambassador on the 3rd of May presented a note to the Porte requiring compliance with the British proposals within ten days. The Turkish ambassador in London was informed by Sir Edward Grey, foreign secretary, that if it were found that Turkish suzerainty in Egypt were incompatible with the rights of the British government to interfere in Egyptian affairs and with the British occupation, the British position in Egypt would be upheld by the whole force of the empire. Thereupon the sultan gave way and agreed (on the 14th of May) that the line of demarcation should start at Rafa and run towards the south-east "in an approximately straight line as far as a point on the gulf of Akaba at least 3 m. distant from Akaba." 1 The Turkish troops were withdrawn from Tabas, and the delimitation of the frontier was undertaken by a joint Turco-Egyptian commission. An agreement was signed on the 1st of October finally settling the frontier line.

With the ending of this dispute and the strengthening of the British garrison in Egypt a demonstration was given of the ability of the protecting power to maintain its position. At the same time encouragement was given to that section of Egyptian society which sought the reform of various Moslem institutions without injury to the principles underlying the faith of Islam: a more truly national movement than that of the agitators who clamoured for parliamentary government.

In April 1907, a few days after the appearance of his report for 1906, in which the "Nationalist" and pan-Islamic movements were shown to be detrimental to the welfare of Egypt, Lord Cromer resigned his post of British agent and consul-general. His resignation, dictated by reasons of health, was described by Sir Edward Grey as "the greatest personal loss which the public service of this country (Britain) could suffer." Lord Cromer's work was in a sense carried on in a state of undernourishment and material fettters with which it was bound when he took up his task in 1883, and with the legitimate expectation that the work he had done would endure. The magnitude of the task he had accomplished is shown by the preceding pages, and it need only be added that the transformation effected in Egypt and the Sudan, during his twenty-four years' occupancy of the British Agency, was carried out in every department under his guidance and inspiration. Lord Cromer was succeeded by Sir Eldon Gorst, who had served in Egypt eighteen years under him, and was at the time of his appointment to Cairo an assistant under secretary of state for foreign affairs.

Notwithstanding, or, rather, as a consequence of, the unexampled material prosperity of the country, 1897 was a year of severe financial crisis, due to over-trading, excessive credit and the prevailing mania induced by the rapid economic progress of Egypt, and aggravated by the unfavourable monetary conditions existing in America and Europe during the latter part of the year. Though the crisis had results disastrous to the speculators, the position of the fellahin was hardly affected; the cotton crop was marketed with regularity and at an average price higher than that of 1906, while public revenue showed a satisfactory increase. The noisy "Nationalist" agitation which was maintained during this period of financial stringency reacted unfavourably on public order. Although the degree of insecurity prevailing in the provinces was greatly exaggerated—serious crime in 1907 being less than in the preceding year—an increasing number of crimes were left untraced to their authors. The release of the Denshawai prisoners in January 1908 and the death of Mustafa Kamel in the following month had a quieting effect on the public mind; while the fact that in the elections (December 1907) for the legislative council and the general assembly only 5% of the electors went to the polls, afforded a striking commentary alike on the appreciation of the average Egyptian of the value of parliamentary institutions and of the claims of the "Nationalist" members of the assembly to represent the Egyptian people. The "Nationalists" were, too, divided into many warring sections—Mahammed Bey Ferid, chosen as successor to Mustafa Kamel, had to contend with the pretensions of several other "leaders." The khedive, moreover, markedly abstained from any association with the agitation of the Nationalists, who viewed with disfavour his highness's personal friendship with Sir Eldon Gorst. The agitators gained their chief strength from the support accorded them by certain Radical politicians in England. A number of members of the council and assembly visited England in July 1908 and were received by Sir Edward Grey, who gave them assurances that Great Britain would always strive to remedy the legitimate grievances of Egyptians.

The establishment of constitutional rule in Turkey in the summer of 1908 excited the hopes of the Egyptian Nationalists, and a deputation was sent to Constantinople to confer with the Young Turk committee. From the Young Turks, however, the deputation received no encouragement for their agitation and returned with the advice to work in co-operation with the British. In view of the rumours current, Sir Eldon Gorst, in the form of an interview in El Mohammam, a widely read native paper, restated (October 1908) the British view as to the occupation of the country and the demand for a parliament. Great Britain, he declared, had no intention of proclaiming a protectorate over Egypt; on the other hand, recent events in Turkey in no way affected the question of self-government in Egypt. It would be folly to think of introducing unrestricted parliamentary government at present, the conditions for its successful working not existing. The "wild and foolish" agitation on this question only served to confirm the impression that the Egyptians were not yet fit to govern themselves. At the same time steps were being taken to give them a much greater part in the management of local affairs. If the Egyptians showed that the existing institutions and the new provincial councils could do useful work, it would prove the best advice for extending their powers. Sir Eldon Gorst's statements were approved by the British government.

In November 1908 Mustafa Fahmi, who had been premier since 1895, resigned and was succeeded by Boutros Pasha, a Copt of marked ability, who had been for several years foreign minister. Boutros incurred the enmity of the "Nationalists" and was murdered in February 1910. (D. M. W.; F. R. C.)

Cameron, Egypt in the Nineteenth Century (London, 1898), a clear and useful summary of events up to 1888; The Story of the British Occupation of Egypt under Isma'il (London, 1899); P. Mourtis, Histoire de l'Egypte (4 vols., Paris, 1855–1858); L. Brehier, L'Egypte de 1798 à 1900 (Paris, 1901); C. de Freycinet, La Question d'Egypte (Paris, 1905). See also MEHMET ALI.

For the period immediately preceding and during the British occupation the standard authority is Lord Cromer's Modern Egypt (London, 1908). Cromer's annual reports from Egypt from 1875 to 1892 and that of the Anglo-Egyptian Sudan from 1892 to 1907 is treated fully. Lord Cromer's annual reports (1888–1906) to the British government on the interests of Egypt should also be consulted. Next in interest are Alfred (Lord) Milner's Mediterranean in Egypt (11th ed., London, 1904) and Sir A. Colvin's The Making of Modern Egypt (London, 1906). Consult also Khedive and Pasha (London, 1884), D. C. F. Moberly Bell (published anonymously): D. M. Wallace, Egypt and the Egyptian Question (London, 1883); W. S. Blunt, Secret History of the English Occupation of Egypt (2nd ed., London, 1907), a partisan record; C. v. Maltzoff, Egypt,
On the 9th the admiral received a report that working parties had been seen in Fort Sisiliah "parbuckling two smooth-bore guns—apparently 32-pounders—towards their respective carriages and slides, which were facing in the direction of the harbour." Fort Sisiliah was an old work at the extreme east of the defences of Alexandria, and its guns do not bear on the harbour. On the 10th an ultimatum was sent to Toulia Pasha, the military commandant, intimating that the bombardment would commence at sunrise on the following morning unless "the batteries on the isthmus of Ras-el-Tin and the southern shore of the harbour of Alexandria" were previously surrendered "for the guns." The fleet prepared for action, and the bearer of the reply, signed by the admiral, went on board and offering to disarm three guns in the batteries named, only succeeded in finding the flagship late at night. This proposal was rejected, and at 7 a.m. on the 11th of July the "Alexandra" opened fire and the action became general. The attacking force was disposed in three groups: (1) the "Alexandra," "Sultan," and "Superb," outside the reef, to engage the Ras-el-Tin and the earthworks under cover; (2) the "Minsk", "Invincible," and "Penelope," under cover to engage the Meks batteries; and (3) the "Inflexible" and "Temeraire," to take up assigned stations outside the reef and to co-operate with the inshore squadron. The gunboats "Beacon," "Bittern," "Condor," "Cygnet," and "Decoy" were to keep out of fire at first and seek opportunities of engaging the Meks batteries. Meks fort was silenced by about 12.45 P.M., and a party from the "Invincible" landed and disabled the batteries. "The first shot of the battle was fired against a battery on the offshore squadron anchored at about 10.30 A.M., and succeeded in silencing Fort Ras-el-Tin at about 12.30 P.M., and Fort Adda, by the explosion of the main magazine, at 1.35 P.M. The "Inflexible" weighed soon after 8 A.M. and engaged Ras-el-Tin, afterwards attacking Forts Pharo and Adda. The "Condor," followed by the "Beacon," "Bittern" and "Decoy," engaged Fort Marabout soon after 8 A.M. till 11 A.M., when the gunboats were recalled. After the works were silenced, the ships moved in closer, with a view to disembark the Egyptian guns. The bombardment ceased at 5 P.M.; but a few rounds were fired by the "Inflexible" and "Temeraire" on the morning of the 12th at the right battery in Ras-el-Tin lines.

The bombardment of the forts of Alexandria is interesting as a gauging of the effect to be obtained from the fire of ships under mutually favourable conditions. The Egyptians at different times during the day brought into action about 33 R.M.L. guns (7-in. to 10-in.), 3 R.B.L. guns (40-p.,) and 120 S.B. guns (6-in. and 10-in.), with an estimated range of from 1000 to 2000 yards. They were located for the most part on the islands about 10-20 sea miles, and were in many cases indifferently mounted. The Egyptian gunners had been little trained, and many of them had only been practised with the most rudimentary marksmanship. The shells of the hulls of the ships only five can with certainty be ascribed to projectiles from rifled guns, and thirty were unquestionably due to the old smoothbore, which were not provided with sights, but the total loss inflicted was 6 killed and 27 wounded. The British ships engaged fired 1741 heavy projectiles (7-in. to 16-in.) and 1457 light (7-p. to 64-p.), together with 33,093 machine-gun and rifle bullets. The result was comparatively small. About 8 riddled guns and 19 smoothbore were disembowelled or damaged and 4 and 1 temporarily put out of action respectively. A considerable portion of this injury was inflicted, after the ships had been silenced, by the fire of the ships. As many as twenty-eight riddled guns and 140 smoothbore would have opened fire on the following day. The Egyptians made quite a good stand as could be expected, but were driven from their guns, which they were unable to use with adequate effect; and the bombardment of Alexandria confirms previous experience that the fire of ships cannot really compete with that of well-mounted and well-handled guns on shore.

In the afternoon of the 12th, fires, which were the work of incendiaries, began to break out in the best quarters of Alexandria; and the town was left to murder and pillage till the following day, when a party of bluejackets and marines was landed at about 3 P.M.

Military intervention being now imperatively demanded, a force of credit for £5,000,000 was passed in the British House of Commons on the 13th of July. Five days later the French government failed to secure a similar vote, and Great Britain was left to deal with the Egyptian question alone.
EGYPT

An expeditionary force detailed from home stations and from Malta was organized in two divisions, with a cavalry division, corps of troops, and a siege train, numbering in all about 25,000 men. An Indian contingent numbering about 7000 constables, complete in all arms and with 15 guns, was prepared for detachments to Suez. General Sir Garnet Wolseley was appointed commander-in-chief, with Lieutenant-General Sir J. Adye as chief of the staff. The plan of operations contemplated the seizure of Ismailia as the base for an advance on Cairo, Alexandria and its suburbs to be held defensively, and the Egyptian forces in the neighbourhood to be occupied by demonstrations. The expeditionary force having rendezvoused at Alexandria, means were taken by Rear-Admiral Hoskins and Sir W. Hewett for the seizure of the Suez canal. Under orders from the former, Captain Fairfax, R.N., occupied Port Said on the night of 19th August, and Commander Edwards, R.N., proceeded down the canal, taking possession of the gares and dredgers, while Captain Fitzroy, R.N., occupied Ismailia after slight opposition. Before nightfall on the 20th of August the canal was wholly in British hands. Meanwhile, leaving Sir E. Hamly in command at Alexandria, Sir G. Wolseley with the bulk of the expeditionary force arrived at Port Said on the 20th of August, a naval demonstration having been made at Abukir with a view to deceive the enemy as to the object of the great movement in progress. The advance from Ismailia now began. On the 21st Major-General Graham moved from Ismailia with about 500 men and a small naval force, occupying Nefiche, the junction with the Suez line, at 1.30 A.M. without opposition. On the 22nd he made a reconnaissance towards Suez, and on the 23rd another to El-Maghar, 4 m. from Nefiche. It now appeared that the enemy had dammed the sweet-water canal and blocked the railway at Tell-el-Mahuta, where entrenchments had been thrown up and resistance seemed to be contemplated. At 4 A.M. on the 24th Sir Garnet Wolseley advanced with 3 squadrons of cavalry, 2 guns, and about 1000 infantry, placed under the orders of Lieutenant-General Willis. The enemy showed in force, estimated at 7000 with 12 guns, and a somewhat desultory action ensued. Reinforcements from Ismailia were ordered up, and the British cavalry, operating on the right, helped to check the enemy's attack, which showed little vigour. At night the troops, now reinforced by the Guards Brigade, an infantry battalion, 2 cavalry regiments and 10 guns, bivouacked on the ground. Early on the morning of the 25th the advance was continued to Tell-el-Mahuta, which the enemy evacuated, while the mounted troops and horse artillery pressed on to Mahsma, capturing the Egyptian camp with 7 guns and a large quantity of ammunition and supplies. On the same evening Major-General Graham, with about 1200 marines (artillery and light infantry), reached Mahsma, and on the following day he occupied Kassassin without opposition. The advance guard had now outrun its communications and was actually short of food, while a considerable force was distributed at intervals along the line Ismailia-Kassassin. The situation on the 27th tempted attack by an enterprising enemy, and Major-General Graham's force, consisting of a squadron of the 10th Hussars, the York and Lancaster Regiment, the Duke of Cornwall's Light Infantry, the Marine Artillery Battalion and two R.H.A. guns, short of ammunition, was in danger of being overwhelmed by vastly superior numbers from Tell-el-Kebir. On the 28th Major-General Graham's troops were attacked, and after repulsing the enemy, made a general advance about 6.45 P.M. The cavalry, summoned by heliograph from Mahsma, engaged them, and by a moonlight charge inflicted considerable loss. The British casualties amounted to 14 killed and 83 wounded. During the full which followed the first action of Kassassin, strenuous efforts were made to bring up supplies and troops and to open up railway communication to the front. On the 9th of September the Egyptians again attacked Kassassin, but were completely repulsed by 9 A.M., with a loss of 4 guns, and were pursued to within extreme range of the guns of Tell-el-Kebir. The British casualties were 3 killed and 78 wounded. The three following days were occupied in concentrating troops at Kassassin for the attack on Tell-el-Kebir, held by about 38,000 men with 60 guns. The Egyptian defences consisted of a long line of trench (42 m.) approximately at right angles to the railway and the sweet-water canal. At about 9.30 A.M. on the 13th of September the advance of about 15,000 men commenced; the 1st division, under Lieutenant-General Willis, was on the right, and the 2nd division, under Lieutenant-General Hamly, was on the left. Seven batteries of artillery, under Brigadier-General Goodenough, were placed in the centre. The cavalry, under Major-General Drury Lowe, was on the right flank, and the Indian contingent; under Major-General Macpherson, starting one hour later, was ordered to move south of the sweet-water canal. The night was moonless, and the distance to be covered about 61 m. The ground was perfectly open, slightly undulating, and generally firm gravel. The conditions for a night march were thus ideal; but during the movement the wings closed towards each other, causing great risk of an outbreak of firing. The line was, however, rectified, and after a halt the final advance began. By a fortunate accident the isolated outwork was just missed in the darkness by the left flank of the 2nd Division; otherwise a premature alarm would have been given, which must have changed all the conditions of the operation. At dawn the Highland Brigade of the 2nd Division struck the enemy's trenches, and carried them after a brief struggle. The 1st Division attacked a few minutes later, and the cavalry swept round the left of the line of entrenchments, cutting down any fugitives who attempted resistance and reaching the enemy's camp in rear. The Indian contingent, on the south of the canal, cooperated, intercepting the Egyptians at the canal bridge. The opposition encountered at some points was severe, but by 6 A.M. all resistance was at an end. The British loss amounted to 58 killed, 379 wounded and 22 missing; nearly 2000 Egyptians were killed, and more than 500 wounded were treated in hospital. An immediate pursuit was ordered, and the Indian contingent, under Major-General Macpherson, reached Zagazig, while the cavalry, under Major-General Drury Lowe, occupied Belbeis and pushed on to Cairo, 65 m. from Tell-el-Kebir, next day. On the evening of the 14th the 10,000 troops occupying Abbassia barracks, and 3000 in the citadel of Cairo, surrendered. On the 15th General Sir Garnet Wolseley, with the brigade of Guards under H.R.H. the Duke of Connaught, entered the city.

The prompt following up of the victory at Tell-el-Kebir saved Cairo from the fate of Alexandria and brought the rebellion to an end. The Egyptian troops at Kafy Dniaar, Abukir and Rosetta surrendered without opposition, and those at Damietta followed on the 23rd of September, after being threatened with attack. On the 25th the khedive entered Cairo, where a review of the British troops was held on the 30th. The expeditionary force was now broken up, leaving about 10,000 men, under Major-General Sir A. Alison, to maintain the authority of the khedive. In twenty-five days, from the landing at Ismailia to the occupation of Cairo, the rebellion was completely suppressed, and the operations were thus signally successful.

The authority of the khedive and the maintenance of law and order now depended absolutely on the British forces left in occupation. Lord Dufferin, who had been sent to Cairo to draw up a project of constitutional reforms, advocated the re-establishment of a native army, not to exceed 3000 to 6000 men, with a proportion of British officers, for purely defence purposes within the Delta; and on the 15th of December 1882 Sir Evelyn Wood left England to undertake the organization of this force, with the title of sirdar. Lord Dufferin further advised the formation of a gendarmerie, which "should be in a great measure a mounted force and empowered with a semi-military character" (despatch of January 1st, 1883). The strength of this military police force was fixed at 4400 men with 2562 horses, and Baker Pasha (General Valentine Baker) was entrusted with its formation, with the title of inspector-general.

In a despatch of the 6th of February 1883 Lord Dufferin desisted
with the Sudan, and stated that Egypt "could hardly be expected to acquiesce in a policy of withdrawal from her Southern territories." At the end of the month he pointed out that the collectivization of the "Unhappily, Egyptian administration in the Sudan had been almost uniformly unfortunate. The success of the present mahdi in raising the tribes and extending his influence over great tracts of country was due to the inefficiency of the government, which was unable to take measures for the protection of the inhabitants to its rule or to maintain order. The consequences had been most disastrous. Within the last year and a half the Egyptians had lost something like 15,000 men, while it was estimated that 40,000 of their opponents had perished.

Moreover, to restore tranquillity in the Sudan, the first step necessary was the construction of a railway from Sennar to Shendi, for what, perhaps, would be more advisable, to Shendi, on the Nile. The completion of this enterprise would at once change all the elements of the problem."

The immense responsibilities involved were most imperfectly understood by the British government. Egyptian sovereignty in the Sudan dates from 1820, when Mehemet Ali sent a large force into the country, and ultimately established his authority over Sennar and Kordofan. In 1856 Suakin and Massawa were assigned to Egyptian rule by the sultan, and in 1870 Sir Samuel Baker proceeded up the Nile to the conquest of the Equatorial provinces, of which General Gordon was appointed governor-general in 1874. In the same year Darfur and Harrar were annexed, and in 1877 Gordon became governor-general of the Sudan, where, with the valuable assistance of Gossi Pasha, he later collared the slave trade in the establishment of an order.

In August 1879 he returned to Cairo, and was succeeded by Raouf Pasha. Misrule and oppression in every form now again prevailed throughout the Sudan, while the slave traders, exasperated by Gordon's stern measures, were ready to revolt. The authority of Egypt was represented by scattered garrisons of armed men, badly officered, undisciplined and largely demoralized. In such conditions a leader only was required to create widespread and dangerous rebellion. In the person of Mahommeh Ahmed, born in 1848, who had taken up his abode on Abba Island, and, acquiring great reputation for sanctity, had actively fomented insurrection. In August 1881 a small force sent by Raouf Pasha to arrest Mahommeh Ahmed was destroyed, and the latter, proclaiming himself the mahdi, stood forth as the champion of revolt. Thus, at the time when the Egyptian army was broken up at Tell-el-Kebir, the Sudan was already in flames. On the 7th of July, 1883, 10,000 men under Yusef Pasha, advancing from Faahoda, were nearly annihilated by the mahdists. Payara and Birket in Kordofan quickly fell, and a few days before the battle of Tell-el-Kebir was fought, the mahdi, with a large force, was besieging El Obeid. That town was captured, after an obstinate defence, on the 17th of January 1883, by which time almost the whole of the Sudan south of Khartum was in open rebellion, except the Bahar-el-Ghazal and the Equatorial provinces, where for a time Lupton Bey and Emin Pasha were able to hold their own. Abd-el-Kader, who had succeeded Raouf, telegraphed to Cairo for 10,000 additional troops, and pointed out that if they were not sent at once four times this number would be required to re-establish the authority of the government in the Sudan. After gaining some small successes, Abd-el-Kader was superseded by Suliman Niagi on the 20th of February 1883, and on the 26th of March Ala-ed-din Pasha was appointed governor-general. Meanwhile 5000 men, who had served in the Egyptian army, were collected, and forcibly despatched to Khartum via Suakin. In March 1883 Colonel William Hicks, late of the Bombay army, who in January had been appointed by the khidive chief of the staff of the army of the Sudan, found himself at Khartum with nine European officers and about 10,000 troops of little military value. The reconquest of the Sudan had been determined upon, although Sir E. Malet recommended that the Egyptian government supply the necessary funds, and that there was great risk of failure, Colonel Hicks, who had resigned his post on the 23rd of July, and had been appointed commander-in-chief, started from Khartum on 9th September, with a total force of about 10,000 men, including non-combatants, for Kordofan. On the 22nd of May Sir E. Malet had informed Sherif Pasha that, "If it is consistent with Lord Dufferin or with me, it must not be supposed that we endorse in any way the contents of his telegram. . . . Her Majesty's Government is not responsible for these expressions; the government which have been undertaken under the authority of His Highness's government."

Colonel Hicks was fully aware of the unfitness of his rabble forces for the contemplated task, and on the 5th of August he telegraphed: "I am convinced it would be better to keep the two rivers and province of Sennar, and wait for Kordofan to settle itself." Early in November the force from Khartum was caught by the mahdists short of water at Kashgil, near El Obeid, and was almost totally destroyed, Colonel Hicks, with all his European officers, perishing. Sinister rumours having reached Cairo, Sir E. Baring (Lord Cromer), who had succeeded Sir E. Malet, telegraphed that "If Colonel Hicks's army is destroyed, the Egyptian government will lose the whole of the Sudan, unless some assistance from the outside is given," and advised the withdrawal to some post on the Nile. On the following day Lord Granville replied: "We cannot lend English or Indian troops; if consulted, recommend abandonment of the Sudan within certain limits"; and on the 25th he added that "Her Majesty's government can do nothing in the matter which would throw upon them the responsibilities for operations in the Sudan." In a despatch of the 3rd of December Sir E. Baring referred to having argued against interference in the Sudan, and on the 13th of December Lord Granville telegraphed that "Her Majesty's government recommend the ministers of khedive to come to an early decision to abandon all territory south of Assuan, or, at least, of Wadi Halfa." On the 4th of January 1884 Sir E. Baring was directed to insist upon the policy of evacuation, and on the 18th General Gordon left London to assist in its execution.

During 1883 there was brought a great accession of power to the mahdi, who had captured about 20,000 rifles, 15 guns and large stores of ammunition. On the Red Sea littoral Osman Digna, a slave dealer of Suakin, appointed amir of the Eastern Sudan, raised the local tribes and invested Sinkat and Tokar. On the 16th of October and the 4th of November Egyptian reinforcements intended for the former place were destroyed, and on the 2nd of December a force of 700 men was annihilated near Tamanich. On the 3rd of December General Valentine Baker, followed by about 2500 men, gendarmerie, blacks, Sudanese and Turks, with 10 British officers, arrived at Suakin to prepare for the relief of Sinkat and Tokar. The khedive appears to have been aware of the risks to be incurred, and in a private letter he informed the general that "I rely upon your prudence and ability not to engage the enemy except under the most favourable circumstances.

The tragedy of Kashgil was repeated on the 4th of February 1884, when General Baker's heterogeneous force, on the march from Tinkitat to Tokar, was routed at El Teb by an inferior body of tribesmen. Of 3755 men, 2375, with 11 European officers, were killed. Suakin was now in danger, and on the 6th of February British bluejackets and marines were landed for the defence of the town.

Two expeditions in the Sudan led by British officers having thus ended in disaster, and General Gordon with Lieutenant-Colonel J. D. Stewart having reached Khartum on the 18th of February, the policy of British non-intervention in regard to Sudan affairs could no longer be maintained. Public opinion in England was strongly impressed by the fact that the Egyptian garrisons of Tokar and Sinkat were perishing within striking distance of the Red Sea littoral. A British force about 4400 strong, with 22 guns, made up of troops from Egypt and from units detached on previous fronts, could now operate at Suakin and placed under the orders of Major-General Sir G. Graham, with Major-Generals Sir R. Buller and J. Davis as brigadiers. News of the fall of Sinkat, where the starving garrison, under Tewfik Bey, made a gallant sortie and was cut
to pieces, reached Suakin on the 12th of February. On the 24th General Graham's force disembarked at Trinitat and received information of the surrender of Tokar. At 8 A.M. on the 29th the force advanced towards Tokar in square, and came under fire at 11.30 A.M. from the enemy entrenched at El Teb. The tribemen made desperate efforts to rush the square, but were repulsed, and the position was taken by 1.00 P.M. by the cavalry, 14th Hussars, under Brigadier-General Sir H. Stewart, became involved in a charge against an unbroken enemy, and suffered somewhat severely. The total British loss was 34 killed and 155 wounded; that of the tribemen was estimated at 1500 killed. On the following day Tokar was reached, and on the 2nd of March the force began its return to Suakin, bringing away about 700 people belonging to the late garrison and the civil population, and destroying 1150 rifles and a quantity of ammunition found in a neighbouring village. On the 9th of March the whole force was back at Suakin, and on the evening of the 11th an advance to Tamai began, and the force bivouacked and formed a zeriba in the evening. Information was brought by a native that the enemy had assembled in the Khor Gnob, a deep ravine not far from the zeriba. At about 8.30 A.M. on the 13th the advance began in echelon of brigade squares from the left. The left and leading square (2nd Brigade) moved towards the khor, and in the front of that point there was a little ravine. The enemy showing in front, the leading face of the square was ordered to charge up to the edge of the khor. This opened the square, and a mass of tribemen rushed in from the small ravine. The brigade was forced back in disorder, and the naval guns, which had been left behind, were temporarily captured. After a severe hand-to-hand struggle, in which the troops behaved with great gallantry, order was restored and the enemy repulsed, with the aid of the fire from the 1st Brigade square and from dismounted cavalry. The 1st Brigade square, having a sufficient field of fire, easily repelled all attempts to attack, and advancing as soon as the situation had been restored, occupied the village of Tamai. The British loss was 109 killed and 104 wounded; of the enemy nearly 2000 were killed. On the following day the force returned to Suakin.

Two heavy blows had now been inflicted on the followers of Osman Digna, and the road to Berber could have been opened, as General Graham and Brigadier-General Sir H. Stewart suggested. General Gordon, questioned on the point, telegraphed from Khartum, on the 7th of March, that he might be cut off by a rising at Shendi, adding, "I think it, therefore, most important to follow up the success near Suakin by sending a small force to Berber." He had previously, on the 29th of February, urged that the Suakin-Berber road should be opened up by Indian troops. This, and General Gordon's proposal to send 300 British troops, who had just arrived, was opposed by Sir E. Baring, who, realizing soon afterwards the gravity of the situation, telegraphed on the 10th of March:

"It has now become of the utmost importance not only to open the road between Suakin and Berber, but to come to terms with the tribes between Berber and Khartum."

The government refused to take this action, and Major-General Graham's force was employed in reconnaissances and small skirmishes, ending in the destruction of the villages in the Terai and the Mora. On the 28th the small force was reassembled at Suakin, and was then broken up, leaving one battalion to garrison the town.

The abrupt disappearance of the British troops encouraged the tribemen led by Osman Digna, and effectually prevented the formation of a native movement, which might have been of great value. The first attempt at intervention in the affairs of the Sudan was made too late to save Sinkat and Tokar. It resulted only in heavy slaughter of the tribesmen, who afforded no direct or indirect aid to General Gordon or to the policy of evacuation. The public announcement of the latter was a grave mistake, which increased General Gordon's difficulties, and the situation at Khartum grew steadily worse. On the 24th of March Sir E. Baring telegraphed:

"The question now is, how to get General Gordon and Colonel Stewart away from Khartum... Under present circumstances, for the effort should be to help and not to hinder the Nile. If Suakin, if it is at all a possible military operation. We all consider that, however difficult the operations from Suakin may be, they are more practicable than any operations from Kortoski against the Nile."

A telegram from General Gordon, received at Cairo on the 19th of April, stated that:

"We have provisions for five months and are hemmed in... Our position will be much strengthened when the Nile rises... Senaar, Kasala and Dongola are quite safe for the present."

At the same time he suggested "an appeal to the millions of America and England" to subscribe money for the cost of 2000 or 3000 nizams (Turkish regulars) to be sent to Berber. A cloud now settled down upon Khartum, and subsequent communications were few and irregular. The foreign office and General Gordon appeared to be somewhat at cross purposes. The former hoped that the garrisons of the Sudan could be extricated without fighting. The latter, judging from the tenor of some of his telegrams, believed that to accomplish this work entailed the suppression of the mahdi's revolt, the strength of which he at first greatly underestimated. He had pressed strongly for the employment of Zobeir as "an absolute necessity for success" (3rd of March); but this was refused, since Sir H. General, advised at this time not to be "unwieldy. On the 9th of March General Gordon proposed, "if the immediate evacuation of Khartum is determined upon irrespective of outlying towns," to send down the "Cairo emplees" and the garrison to Berber with Lieutenant-Colonel J. D. Stewart, to resign his commission, and to proceed with the stores and the steamers to the equatorial provinces, which he would consider as placed under the king of the Belgians. On the 11th of March Lord Granville gave full power to General Gordon to evacuate Khartum and save that garrison by conducting it himself to Berber without delay," and expressed a hope that he would not resign his commission.

By the end of March 1884 Sir E. Baring and the British officers in Egypt were convinced that force would have to be employed, and the growing danger of General Gordon, with the grave national responsibility involved, began to be realized in Great Britain. Sir Henry Gordon, however, who was in personal communication with Mr. Gladstone, who realized that his brother was in no peril, and for some time disbelieved in the need for a relief expedition. Meanwhile it was at least necessary to evolve some plan of action, and on the 8th of April the adjutant-general addressed a memorandum to the secretary of state for war detailing the measures required for placing 6000 British troops in the neighbourhood of Shendi. The battle of the routes began much earlier, and was continued for some months. Practically the choice lay between the road to Berber and the Suakin-Berber road. The first involved a distance of 1650 m. from Cairo along a river strewn with cataracts, which obstructed navigation to all but small boats, except during the period of high water. So great was this obstruction that the Nile had never been a regular trade route to the Sudan. The second entailed a desert march of about 250 m., of which one section, Obak-Bir Mahoba (52 m.), was waterless, and the rest had an indifferent water supply (except at Aribat, about halfway to Berber), capable, however, of considerable development. From Berber the Nile is followed (210 m.) to Khartum. This was an ancient trade route with the Sudan, and had been used without difficulty by the reinforcements sent to Hicks Pasha in 1883, which were accompanied by guns on wheels. The authorities in Egypt, headed by General Stephenson, subsequently supported by the Admiral Lord John Hay, who sent a naval officer to examine the river as far as Dongola, were unanimous in favour of the Suakin-Berber route. It would be the first Major-General Sir A. Clarke, then inspector-general of fortifications, strongly urged this plan, and proposed to begin at once a metre gauge railway from Suakin, to be constructed by Indian labour under officers skilled in laying desert lines. Some preliminary arrangements were made, and on the 14th of June the government
sanctioned certain measures of preparation at Suakin. On the other side were the adjutant-general (Lord Wolseley) and a small number of officers who had taken part in the Red River expedition of 1879. The memorandum of the adjutant-general above referred to was based on the hypothesis that Khartum could not hold out beyond the 15th of November, and that the expedition should reach Berber by the 20th of October. Steamers were to be employed in such reaches as proved practicable, but the force was to be conveyed in special whale-boats, by which "the difficulty of transport is reduced to very narrow limits." The mounted force was to consist of 400 men on native horses and 450 men on horses or camels. The question of routes continued to be the subject of animated discussion, and on the 29th of July a committee of three officers who had served in the Red River expedition reported:

"We believe that a brigade can easily be conveyed in small boats from Cairo to Dongola in the time stated by Lord Wolseley; and, further, that it should be necessary to send a still larger force by water to Khartum, that operation will present no insuperable difficulties."

This most inconclusive report, and the baseless idea that the adoption of the Nile route would involve no chance of bloodshed, which the government was anxious to avoid, seem to have decided the question. On the 8th of August the secretary of state for war informed General Stephen-son that "the time had arrived when some further measures for obtaining accurate information as to his (General Gordon's) position, and, if necessary, for rendering him assistance, should be adopted." General Stephenson still urged the Suakin-Berber route, and was informed on the 26th of August that Lord Wolseley would be appointed to take over the command in Egypt for the purposes of the expedition, for which a vote of credit had been taken in the House of Commons on the 5th of August. On the 9th of September Lord Wolseley arrived at Cairo, and the plan of operations was somewhat modified. A camel corps of 1100 men selected from twenty-eight regiments at home was added, and the "fighting force to be placed in line somewhere in the neighbourhood of Shendi" was fixed at 5400. The construction of whale-boats began on the 17th of August, and the first batch arrived at Wadi Halfa on the 14th of October, and on the 25th the first boat was hauled through the second cataract. The mounted forces proceeded up the banks, and the first half-battalion embarked at Gemai, 870 m. from Khartum, on the 9th of November, ten days before the date to which it had been assumed General Gordon could hold out. In a straggling procession the boats worked their way up to Korti, piloted by Canadian voyageurs. The labour was very great, and the troops, most of whom were having their first lesson in rowing, bore the privations of their unaccustomed conditions with admirable cheerfulness. By the 25th of December 2220 men had reached Korti, of whom about 800 only had been conveyed by the whale-boats, the last of which did not arrive till the 27th of January. Beyond Korti lay the very difficult section of the river to Abu Hamed, which was quite unknown. Meanwhile news of the loss of the "Abbas" and of the murder of Colonel J. D. Stewart and his party on the 18th of September had been received. A letter from Gordon, dated the 4th of November and received on the 17th of November, stated that he expected to await the expedition at Metemma, and added, "we can hold out forty days with ease; after that it will be difficult." In his diary, on the 13th of December, when his difficulties had become extreme, he noted that "if the expeditionary force does not reach Khartum in ten days, the town may fall."

"It was clear at Korti that something must be done at once; and on the 15th of December 1100 men, with 2200 camels, under General Sir H. Stewart, were despatched to occupy Jakdul wells, 96 m. on the desert route to Metemma. Stewart returned on the 5th of January, and started again on the 8th, with orders to establish a fort at Abu Klea and to occupy Metemma. The Desert Column, 1800 men, with 2880 camels in poor condition and 153 horses, found the enemy in possession of Abu Klea wells on the 16th, and was desperately attacked on the 17th. The want of homogeneity of the force, and the unaccustomed tactics imposed upon the cavalry, somewhat hampered the defence, and the square was broken at the left rear corner. Driven back upon the camels in the centre, the troops began to fall back, but the fort was quickly restored, and the attack was repulsed, with a loss of 74 killed and 94 wounded. At least 1100 of the enemy were killed. The wells being occupied and a zariba formed, the column started on the evening of the 18th. The wrong road was taken, and great confusion occurred, during the night, but at dawn this was rectified; and after forming a rough fort under fire, by which General Sir H. Stewart was severely wounded, the column got away unhurt at 5 P.M. The square was again heavily attacked, but the Arabs could not get to close quarters and in the evening a bivouac was formed on the Nile. The British losses on this day were 23 killed and 98 wounded. The Desert Column was now greatly exhausted. On the 20th the village of Gubat was occupied; and on the following day Sir C. Wilson, on whom the command had devolved, advanced against Metemma, which was found too strong to assault. On this day General Gordon's four steamer arrived; and on the morning of the 24th Sir C. Wilson, with 20 British soldiers in red coats and about 280 Sudanese, started in the "Bordein" and "Telahawiyeh" for Khartum. The "Bordein" grounded on the following day, and again on the 26th, by which twenty-four hours were lost. At 11 A.M. on the 28th Khartum was sighted, and it soon became clear that the town was in the hands of the enemy. After reconnoitring farther, the steamers turned and proceeded down stream under a heavy fire: the Sudanese crew showing signs of disaffection. The "Telahawiyeh" was wrecked on the 29th of January and the "Bordein" on the 31st, Sir C. Wilson's party being rescued on the 4th of February by Lord C. Beresford in the "Safeh," which had come up from Gubat on receipt of news carried there by Lieutenant Stuart Wortley in a row-boat. Khartum had been taken and General Gordon killed on the morning of the 26th of January 1885, having thus held out thirty-four days beyond the date when he had expected the end. The garrison had been reduced to starvation; and the arrival of twenty British soldiers, with orders to return at once, could not have affected the situation. The situation of the Desert Column and of its transport was most imperfectly understood at Korti, where impossible plans were formed. Fortunately Major-General Sir R. Buller, who arrived at Gubat on the 11th of February, decided upon withdrawal, thereby averting impending disaster, and by the 16th of March the Desert Column had returned to Korti. The advance from Korti of the River Column, under Major-General Earle, began on the 28th of December, and great difficulties of navigation were encountered. On the 10th of February an action was fought at Kirbekan with about 800 of the enemy, entailing a loss of 10 killed, including Major-General Earle, and 47 wounded. The column, now commanded by Brigadier-General Brandenbury, continued its slow advance, and on the morning of the 24th of February it was about 26 m. below Abu Hamed, a point where the Koreko desert route strikes the Nile, 350 m. from Khartum. Here it received orders to retire, and it reached Korti on the 8th of March. The verbal message received from General Gordon on the 30th of December 1884 rendered the extreme danger of the position at Khartum painfully apparent, and the general of state for war, acting in the name of E. Bence, a naval officer, offered to make an active demonstration from Suakin on operations. This proposal Lord Wolseley demurred, but asked that ships of war should be sent to Suakin, and that "marines in red coats should be frequently landed and exercised." Lord Hartington replied that the government did not consider that a demonstration of this kind could be effective, and again suggested stronger measures. On the 8th of January 1885 Lord Wolseley repeated that "the measures you propose will not assist my operations against Khartum," adding:"
MILITARY OPERATIONS 1885.

"I have from first endeavoured to impress on government that I am strong enough to relieve Khartoum, and believe in being able to send them. I am returning by way of Berber, to Suakin, to open road and crush Osman Digna."

On this very day the small Desert Column started from Korti on its hazardous mission to the relief of a town fully 270 m. distant, held by a starving garrison, and invested by 30,000 fighting men, mostly armed with good rifles. Before reaching the Nile the Desert Column had lost 50 men and was unable to take Metemma, while its transport had completely broken down. On the 8th of February Lord Wolseley telegraphed, "The sooner you can now deal with Osman Digna the better," and recommenced the despatch of Indian troops to Suakin, to "co-operate with me in keeping road to Berber open." On the 11th of February, the day on which Sir R. Buller most wisely decided to withdraw the Desert Column from a position of extreme danger, it was determined at Korti that the River Column should proceed to attack Berber, and Lord Wolseley accepted the proposal of the government to make a railway from Suakin, telegraphing to Lord Harington:

"By all means make railway by contract to Berber, or as far as you can, during summer. It will be invaluable as a means of supply, and makes any offensive operations possible. Contract to be, if possible, for so much per ton military stores and supplies and men carried, per mile."

Every effort was now concentrated upon sending an expeditionary force to Suakin, and before the end of March about 13,000 men, including a brigade from India and a field battery from New South Wales, with nearly 7000 camels and 1000 mules, were there assembled. Lieutenant-General Sir G. Graham was placed in command of this force, with orders to break down the power of Osman Digna and to press the construction of the railway towards Berber. The troops at Suakin, on arrival, were much harried by small night attacks, which ceased as soon as the scattered camps were drawn together. On the 19th of March Sir G. Graham, with the cavalry brigade and the infantry of the Indian contingent, reconnoitred as far as Hashin, finding the country difficult on account of the dense mimoso scrub. The enemy occupied the hills and fired upon the cavalry. On the 20th Sir G. Graham, with about 3000 men, again advanced to Hashin, and Deibblat hill was taken by the Berkshire regiment and the Royal Marines. A squadron of the 9th Royal Lancers, which was dismounted in the thick bush, was driven back with the loss of 9 men; but elsewhere the Arabs never succeeded in closing, and the troops returned to Suakin in the afternoon, leaving the East Surrey regiment occupying some hills near Homs village. The total British loss was 9 killed and 39 wounded.

The 22nd of March a force, consisting of two British and three Indian battalions, with a naval brigade, a squadron of lancers, two companies of engineers, and a large convoy of camels carrying water and supplies, under Major-General Sir J. McNeill, started from Suakin for Tamai, with orders to form a half-way seriba. The advance was much impeded by the dense bush, and the force halted at Tofrik, about 8 m. out, at 10.30 A.M. A native had brought information that the enemy intended to attack while the seriba was being formed, and this actually occurred. The force was caught partly unprepared soon after 2.30 P.M., and severe fighting took place. The enemy were repulsed in about twenty minutes, the naval brigade, the Berkshire regiment, the Royal Marines, and the 15th Sikhs showing the greatest gallantry. The casualties, including those among non-combatants, were 150 killed, 148 missing, and 174 wounded. More than 500 camels were killed. The tribesmen lost more than 1000 killed. As soon as firing was heard at Suakin, Sir G. Graham, with two battalions of Guards and a battery of horse artillery, started for Tofrik, but returned on being assured that reinforcements were not required. On the 24th and 26th convoys proceeding in square to Tofrik were attacked, the enemy being repulsed without difficulty. On the end of April a force exceeding 7000 men, with 14 guns and 1000 transport animals, started from Suakin at 4.30 A.M., and bivouacked twelve hours later at Tesela Hill. Next morning an advance was made towards Tamai, and a number of huts in the Khor Ghob were burned. The force then returned to Suakin. The railway was now pushed on without interruption, reaching Otao on the 30th. On the night of 1st May a combined movement was made from Suakin and Otao, which resulted in the surprise and break-up of a force of the enemy under Mahommed Sardup, and the capture of a large number of sheep and goats. The moral effect of this operation was marked, and large numbers of tribesmen placed themselves unconditionally at the disposal of Sir G. Graham. A great native movement could now have been organized, which would have kept the route to Berber and enabled the railway to be rapidly pushed forward.

Meanwhile many communications had passed between the war office and Lord Wolseley, who at first believed that Berber could be taken before the summer. In a long dispatch of the 6th of March he discussed the general situation, and pointed out that although the force at his disposal "was amply sufficient" for raising the siege of Khartum and defeating the mahdi, the conditions were changed by the fall of the town. It was now "impossible." When twelve additional British battalions, four squadrons of British cavalry, and two R.H.A. batteries, together with a large extension of the Wadi Halfa railway, eleven steamers, and three hundred more whale-boats, would be required. He considered it necessary to hold Dongola, and he reported that he was "distributing this army along the left bank of the Nile, on the open reach of water," between the Manock cataract and Abu Dom, opposite Meroe. On the 30th of March Lord Wolseley quitted the army and proceeded to Cairo. A cloud having arisen on the frontiers of Afghanistan, the withdrawal of the troops from the Sudan was ordered on the 11th of May. On the formation of Lord Salisbury's cabinet, the new secretary of state for war, Mr W. H. Smith, inquired whether the retirement could be arrested, but Major-General Sir R. Buller reported that the difficulties of reoccupation would be great, and that if Dongola was to be held, a fresh expedition would be required. On the 22nd of June, before the British rearguard had left Dongola, the mahdi died. The withdrawal of the Suakin force began on the 17th of May, and the friendly tribes, deprived of support, were compelled to make terms with Osman Digna, who was soon able to turn his attention to Kassala, which capitulated in August, nearly at the same time as Sennar.

The failure of the operations in the Sudan had been absolute and complete, and the reason is to be sought in a total misconception of the situation, which caused vacillation and delay, and in the choice of a route, by which, having regard to the date of the decision, the relief of General Gordon and Khartum was impossible.

(M. S. C.)

MILITARY OPERATIONS IN EGYPT AND THE SUDAN, 1885 TO 1896

The operations against Mahdiism during the eleven years from the end of the Nile expedition and the withdrawal from the Sudan to the commencement of the Dongola campaign will be more easily understood if, instead of narrating them in one chronological sequence, the operations in each province are considered separately. The mahdi, Mahommed Ahmed, died at Omdurman on the 22nd of June 1885. He was succeeded by the principal khilifa, Abdullah el Taaiaha, a Baggaram Arab, who for the next thirteen years ruled the Sudan with despotic power. Cruel, vicious, unscrupulous and strong, the country groaned beneath his oppression. He removed all possible rivals, concentrated at Omdurman a strong military force composed of men of his own tribe, and maintained the ascendency of that tribe over all others. As the British troops retired to Upper Egypt, his followers seized the evacuated country, and the khilifa cherished the idea, already formulated by the mahdi, of the conquest of Egypt, but for some years he was too much
occupied in quelling risings, massacring the Egyptians in the Sudan, and fighting Abyssinia, to move seriously in the matter.

Upper Egypt.—Mohammed el Kheir, dervish amir of Dongola, however, advanced towards the frontier in the autumn of 1885, and at the end of November came in touch with four rebellious forces, composed of some 30,000 men, composed in nearly equal parts of British and Egyptian troops. A month of harassing skirmishes ensued, during which the Egyptian troops showed their mettle at Mograna, where 200 of them held the fort against a superior number of dervishes, and in battles at Ambigol, Kosha and Firket. Sir Frederick Stephenson, commanding the British army of occupation in Egypt, then concentrated the frontier field force at Firket, and attacked the main body of the enemy at Ginnis on the 30th of December 1885, completely defeating it and capturing two guns and twenty banners. It was here the new Egyptian army received its baptism of fire and acquitted itself very creditably. Although checked, the dervishes were not discouraged, and continued to press upon the frontier in frequent raids, and thus in many bloody skirmishes the fighting qualities of the Egyptian troops were developed. In April 1886 the frontier was divided back to Wah, and a fortified camp at the latter place was taken by the Egyptians in Italy, who attempted a sortie but were repulsed.

In October 1886 Wad en Nejumi, the amir who had defeated Hicks Pasha in Kordofan three years before, and led the assault at Khartum when General Gordon was slain in January 1885, replaced.Mahmoudel Kheir as "commander of the force for the conquest of Egypt," and brought large reinforcements to Dongola. An advanced column under Nur-el-Kanzi occupied Sarras in April 1887, was attacked by the Egyptian force under Colonel H. Chermside on the 28th of that month, and after a stubborn resistance was defeated with great loss. Nur-el-Kanzi was killed and ten standards taken.

The troubles in Darfur and with Abyssinia (q.v.) induced the khalifa to reduce the garrisons of the north; nevertheless, the dervishes reoccupied Sarras, continued active in raids and skirmishes, and destroyed the railway south of Sarras, which during the Nile expedition of 1884 and 1885 had been carried as far as Akasha. It was not until May 1889 that an invasion of the frontier on a large scale was attempted. At this time the power and prestige of the Khalifa were at their height: the rebellions in Darfur and Kordofan had been crushed, and Kheir el Din was dead, and even the dervish defeat by the Abyssinians had been converted by the death of King John and the capture of his body into a success. It was therefore an opportune time to try to sweep the Turks and the British into the sea. On the 22nd of June Nejumi was at Sarras with over 6,000 fighting men and 8,000 followers. On the 2nd of July Colonel J. Wodehouse headed off to a part of this force from the river at Argin, and, after a sharp action, completely defeated it, killing 900, among whom were many important amis, and taking 50 prisoners and 12 banners, with very small loss to his own troops. A British brigade was on its way up stream, but the sirdar, who had already arrived to take the command in person, decided not to wait for it. The Egyptian troops, with a squadron of the 20th Hussars, concentrated at Toski, and thence, on the 3rd of August, General Grenfell, with slight loss, gained a decisive victory. Wad en Nejumi, most of his amis, and more than 1,200 Arabs were killed; 400 prisoners and 147 standards were taken, and the dervish army practically destroyed. No further serious attempts were made to disturb the frontier, of which the most southerly outpost was at once advanced to Sarras.

The Egyptian troops had occupied the Sudan, and fighting Abyssinia, moving seriously in the matter.

The Eastern Sudan.—In 1884 Colonel Chermaide, governor of the Red Sea littoral, entered into arrangements with King John of Abyssinia for the relief of the beleaguered Egyptian garrisons. Geri, Amadib, Senhit and Gallabat were, in consequence, duly succoured, and their garrisons and Egyptian populations brought away to the coast by the Abyssinians in 1885. Unfortunately famine compelled the garrison of Kassala to capitulate on the 30th of July of that year, and Osman Digna hurried there from Tamai to raise a force with which to meet the Abyssinian general, Ras Alus, who was preparing for its relief. By the end of August Osman Digna had occupied Kufit, in the Bara country, with 10,000 men and entrenched himself. On the 23rd of September Ras Alus attacked him there with an equal number of men and routed him with great slaughter. Over 3,000 dervishes with their principal amis, except Osman Digna, lay dead on the field, and many more were killed in pursuit. The Abyssinians lost 40 officers and 1,500 men killed, besides many more wounded. Instead of marching on to Kassala, Ras Alus, who at this time was much offended by the transfer of the northern red sea from the Egyptians by the treaty of Hadda, decided to stay and absolutely refused to make any further efforts to extricate Egyptian garrisons from the grip of the khalifa. Meanwhile Osman Digna, who had fled from Kufit to Kassala, wreaked his vengeance upon the unhappy captives at Kassala.

In the neighbourhood of Suakin there were many tribes disaffected to the khalifa's cause, and in the autumn of 1886 Colonel H. Kitchener, who was at the time governor of the Red Sea littoral, judiciously arranged a combination of them to overthrow Osman Digna, with the result that his stronghold at Tamai was captured on the 7th of October, 200 of his men killed, and 50 prisoners, 17 guns and a vast store of rifles and ammunition captured. For about a year there was comparative quiet. Then at the end of 1887 Osman Digna again advanced towards Suakin, but his force at Taroi was routed by the 'Friendlies,' and he fell back on Handub. Kitchener, unsuccessfully endeavoured to capture Osman Digna on the 17th of January 1888, but in the attack was himself severely wounded, and was shortly after invalided. Later in the year Osman Digna collected a large force and besieged Suakin. In December the sirdar arrived with reinforcements from Cairo, and on the 20th sailed out and attacked the dervishes in their trenches at Gemaiza, clearing the whole line and inflicting considerable loss on the enemy, who retired towards Handub, and the country was again fairly quiet for a time. During 1889 and 1890 Handub was held, but the centre had been allowed to be occupied for the khalifa. In January 1891 Osman Digna showed signs of increased activity, and Colonel (afterwards Sir Charles) Holled Smith, then governor of the Red Sea littoral, attacked Handub successfully on the 27th and occupied it, then seized Trinkitat and Teb, and on the 19th of February fought the decisive action of Afaif, occupied Tokar, and drove Osman Digna back to Temrin with a loss of 700 men, including all his chief amis. This action proved the final blow to the dervish power in the neighbourhood of Suakin, for although raiding continued on a small scale, the tribes were growing tired of the khalifa's rule and refused to support Osman Digna.

In the spring of 1891, an agreement was made between England and Italy by which the Italian forces in Eritrea were at liberty, if they were capable of capturing Kassala, which lay close to the western boundary of Egypt, under the condition that they restored it to Egypt at a future day when required to do so. Three years passed before they availed themselves of this agreement. In 1893 the dervishes, 12,000 strong, under Ahmed Ali, invaded Eritrea, and were met on the 29th of December at Agordat by Colonel Arimondi with 2000 men of a native force. Ahmed Ali's force was completely routed and himself killed, and in the following July Colonel Baratieri, with 2500 men, made a fine forced march from Agordat, surprised and captured
Kassala on the 17th of that month, and continued to hold it for three years and a half.

The Abyssinian Frontier.—On the Abyssinian frontier Ras Adal was now in possession of the considerabe force of Abyssinians early in 1886, and in June of that year he invaded Gallabat and defeated the dervishes on the plains of Madana; the dervish amir Mahomed W. bin Kamal died at this battle.

In January 1887 the year the amir Yunis ed Dezen made two successful raids into Abyssinian territory, upon which Ras Adal collected an enormous army, said to number 200,000 men. With the aid of the Sudan khalifs Khalil Hamdan Abu Angar, a very skilful leader, with an army of over 80,000 men against him. Abu Angar entered Abyssinia and, in August 1887, attacked Ras Adal in the plains of Dembelo, the latter engaged the Abyssinians and captured their camp, and marched on Gondar, the ancient capital of Abyssinia, which he sacked, and then returned into Gallabat. Ras Adal divided in a second battle, and was driven from Gondar, the Abyssinians marched, in February 1889, with an enormous army to Gallabat, where the amir Zeki Tumal commanded the khilifa’s forces, some 60,000 strong, and had strongly fortified the town and the camp. A small party of dervishes still held a zemba when King John was storms and burnt the town, and took thousands of prisoners. A small party of dervishes still held a zemba when King John was still held when King John was storms and burnt the town, and took thousands of prisoners. of their captivity at Omdurman by Father Ohrwalder and Slatin Bey (published in 1892 and 1896), stirred public opinion in Great Britain, and brought the question of the recovery of the Sudan into prominence. A change of ministry took place in 1895, and Lord Salisbury's cabinet, which had consistently assailed the Egyptian policy of the old, was not unwilling to consider whether the flourishing condition of Egyptian finance, the prosperity of the country and the settled state of its affairs, with a capable and proved little army ready to hand, did not warrant an attempt being made to recover gradually. The Sudan provinces abandoned by Egypt in 1885 on the advice of Mr Gladstone's government, were reconquered at Wadi Halfa, the railway reconstruction, under Lieutenant E. P. Girouard, R.E., pushed southward; and a telegraph line followed the advance. At the commencement of the campaign the Egyptian army, including reserves, consisted of 16 battalions of infantry, of which 6 were Sudanese, 10 squadrons of cavalry, 5 batteries of artillery, 3 companies of garrison artillery, and 8 companies of camel corps, and it possessed 13 gunboats for river work. Colonel H. M. L. Rundle was chief of the staff; Major F. R. Wingate was head of the intelligence department, with Slatin Bey as his assistant; and Colonel A. Hunter was in command of Sarras, and south. The 1st battalion of the North Staffordshire regiment moved up from Cairo to join the Egyptian army.

In the meantime the advance to Akasha had already relieved the pressure at Kassala, Osman Digna having withdrawn a column from the investing army and prevented the arrival of the Nile. On the 6th Kitchener moved to the attack of Firket 16 m. away, where the amir Hamuda, with 3000 men, was encamped. The attack was made in two columns: one, under Colonel Hunter, marching along the river-bank, approached Firket from the north; while the other, under Major Burn-Murdoch, making a detour through the desert, approached it from the south. The co-operation of the two columns was admirably timed, and on the morning of the 7th the devils were surrounded, and, after a sharp fight, Hamuda and many amirs and about 1000 men were killed, and 500 prisoners taken. The dash and discipline of the Egyptian troops in this victory were a good augury for the future.

By the end of June the railway was advanced beyond Akasha, and headquarters were at Kossa, 10 m. farther south. Cholera and fever were busy both with the North Staffordshire regiment at Gemal, whither they had been moved on its approach, and with the Egyptian troops at the front, and carried off many officers and men. The railway reached Kossa early in August; the cholera disappeared, and stores were collected and arrangements steadily made for a farther advance. The North Staffordshire moved up to the front, and in September the army moved on Kerma, which was found to be evacuated, the devils having crossed the river to Hafi. There they were attacked by the gunboats. Kitchener's artillery from the opposite bank, and forced to retire, with their commander, Wad Bishara, seriously wounded. Dongola was bombarded by the gunboats and captured by the army on the 23rd of September. Bishara and his men retreated, but were pursued by the Egyptians until the retreat became a hopeless rout. Guns, small arms and ammunition, with large stores of grain and dates, were captured, many prisoners taken, while hundreds surrendered voluntarily, among them a brother of the amir Wad en Nejmi. The devils Dongola army had practically ceased to exist. Debba was seized on the 3rd October, Korti and Merawi occupied soon after, and the principal sheries came in and submitted to the sirdar. The Dongola campaign was over, and the province recovered to Egypt. The Indian brigade at Suakin returned to India, and was replaced by Egyptians. The North Staffordshire returned to Cairo. The work of consolidation began, and preparations were made for a further advance which was deferred until the 23rd of January.

The railway up the right bank of the Nile was continued to Kerma, in order to evade the difficulties of the 3rd cataract; but the sirdar had conceived the bold project of cutting off the great angle of the Nile from Wadi Halfa to Abu Hamed, involving nearly 600 m. of navigation and including the 4th cataract, by constructing a railway across the Nubian desert, and so bringing his base at Wadi Halfa within a few hours of his force, when it should have advanced to Abu Hamed, instead of ten days. Early in 1897 this new line of railway was commenced from Wadi Halfa across the great Nubian desert 250 m. to Abu Hamed. The first-mentioned line reached Kerma in May, and by July the second had advanced 130 m. into the desert towards Abu Hamed, when it became necessary, before it was carried farther, to secure that terminus by an advance from Merawi.

In a few hours his hour was not idle. He occupied Abu Klua wells and Metemma; recalled the amir Ibrahim Khalil, with 4000 men, from the Chegira; brought to Omdurman the army of the west under Mahamud—some 10,000 men; entrusted the line of the Atbara—Ed Damer, Adarama, Asubri and El Fasher—to Osman Digna; constructed defences in the Shabulka gorge; and personally superintended the organization and drill of the forces gathered at Omdurman, and the collection of vast stores of food and supplies of camels for offensive expeditions.

Towards the end of June the chief of the Jaalib tribe, Abdalla was said, who occupied Metemma, angered by the khaliifa, made his submission to Kitchener and asked for support, at the same time foolishly sending a defiant letter to the khaliifa. The sirdar sent him rifles and ammunition across the desert from Korti; but before they arrived, Mahamud's army, sent by the khaliifa, swept down on Metemma on the 1st of July and massacred Abdalla with 1000 men and his garrison. The 29th of July, after several reconnaissances, Major-General Hunter, with a flying column, marched up the Nile from Merawi to Abu Hamed, 133 m. distant, along the edge of the Monassir desert. He arrived on the 7th of August and captured it by storm, the devils losing 250 killed and 50 prisoners. By the end of the month the gunboats had surmounted the 4th cataract and reached Abu Hamed. Berber was at Gemal, and the remainder of the force, under Major Hunter on the 5th of September, in the following month a large force was entrenched there. The khaliifa, fearing an attack on Omdurman, moved Osman Digna from Adarama to Shendi. In the 23rd of October Hunter, with a flying column lightly equipped, left
Berber for Adarama, which he burned on the 2nd of November, and after reconnoitring for 40 m. up the Atbara, returned to Berber. The Nile was falling, and Kitchener decided to keep the gunboats above the impassable rapid at Um Tuir, 4 m. north of the confluence of the Atbara with the Nile, where he constructed a fort. The gunboats made repeated reconnaissances up the river, bombarding Metemma with effect. The railway reached Abu Hamed on the 4th of November, and was pushed rapidly forward along the right bank of the Nile towards Berber.

The forces of the khali‘a remaining quiet, the sirdar visited Kassala and negotiated with the Italian General Caneva for its restoration to Egypt. The Italians were anxious to leave it; and on Christmas, Colonel Roy, Colonel (afterwards General Sir Charles) Parsons, with an Egyptian force from Suakin, took it formally over, together with a body of Arab irregulars employed by the Italians. These troops were at once despatched to capture the dervish posts at Asabri and El Fisher, which they did with small loss.

On his return from Kassala to Berber the sirdar received information of an intended advance of the khali‘a northward. He at once ordered a concentration of Egyptian troops towards Berber, and telegraphed to Cairo for a British brigade. By the end of January the concentration was complete, and the British brigade, under Major-General Gatacre, was at Dakkeh, south of Abu Hamed. Disagreement among the khali‘a’s generals postponed the dervish advance and gave Kitchener much-needed time. But at the end of February, Mahmud crossed the Nile to Shendi with some 12,000 fighting men, and with Osman Digna advanced along the right bank of the Nile to Al-ia, where he struck across the desert to Nakhala, on the Atbara, intending to turn Kitchener’s left flank at Berber. The sirdar took up a position at Ras el Hudi, on the Atbara. His force consisted of Gatacre’s British brigade (1st Warwicks, Lincolns, Seaforths and Cameroners) and Hunter’s Egyptian division (3 brigades under Colonels Maxwell, MacDonald and Lewis respectively), Broadwood’s cavalry, Tuway’s camel corps and Long’s artillery. The dervish army reached Nakhala on the 30th of March, and entrenched themselves there in a formidable zibara. After several reconnaissances in which fighting took place with Mahmud’s outposts, it was ascertained from prisoners that their army was short of provisions and that great leakage was going on. Kitchener, therefore, did not hurry. He sent his fleet up the Nile and captured Shendi, the dervish depot, on the 27th of March. On the 4th of April he advanced to Abadar. A final reconnaissance was made on the 5th. On the following day he bivouacked at Undabia, where he constructed a strong zibara, which was garrisoned by an Egyptian battalion, and on the night of the 7th he marched to the attack of Mahmud’s zibara, which, after an hour’s bombardment on the morning of the 8th of April, was stormed with complete success. Mahmud and several hundred dervishes were captured, 40 amirs and 3000 Arabs killed, and many more wounded; the rest escaped to Gedaref.

The sirdar’s casualties were 80 killed and 472 wounded. Preparations were now made for the attack on the khali‘a’s force at Omdurman; and in the meantime the troops were camped in the neighbourhood of Berber, and the railway carried on to the Atbara. At the end of July reinforcements were forwarded from Cairo; and on the 24th of August the following troops were concentrated for the advance at Wad Hamad, above Metemma, on the western bank of the 6th cataract—British division, under Major-General Gatacre, consisting of 1st Brigade, commanded by Lieutenant Colonel A. H. Watling; 2nd Brigade, commanded by Lieutenant Colonel A. H. Watling; 1st Warwicks, Lincolns, Seaforths and Cameroners; and 2nd Brigade, commanded by Colonel the Hon. N. G. Lyttelton (1st Northumbrelands and Grenadier Guards, and Lancashire and Rifle Brigade); Egyptian division, under Major-General Hunter, consisting of four brigades, commanded by Colonels MacDonald, Maxwell, Lewis and Collinson; mounted troops—21st Lancers, camel corps, and Egyptian cavalry; artillery, under Colonel Long. 2 British batteries, 5 Egyptian batteries, and 20 machine guns; detachment of Royal Engineers. The fleet, under Commander Keppel, R.N., consisted of 10 gunboats and 5 transport steamers. The total strength was nearly 26,000 men.

While the army moved along the west bank of the river, a force of Arab irregulars or “Friends” marched along the east bank under command of Colonel S. F. W. Maude, Lieutenant Wood, to clear it of the enemy as far as the Blue Nile; and on the 1st of September the gunboats bombarded the forts on both sides of the river and breached the great wall of Omdurman. Kitchener met with no opposition; and on the 1st of September the army bivouacked in zibara at Egeiga, on the west bank of the Nile, within 4 m. of Omdurman. Here, on the morning of the 2nd of September, the khali‘a’s army, 40,000 strong, attacked the zibara, but was repulsed with slaughter. Kitchener then ordered to move towards Omdurman, when he was again twice fiercely attacked on the right flank and rear, MacDonald’s brigade bearing the brunt. MacDonald distinguished himself by his tactics, and completely repulsed the enemy. The 21st Lancers gallantly charged a body of 2000 dervishes which was unexpectedly met in a khor on the left flank, and drove them westward, the Lancers losing a fifth of their number in killed and wounded. The khali‘a was now in full retreat, and the sirdar, sending his cavalry in pursuit, marched into Omdurman. The dervish loss was over 10,000 killed, as many wounded, and 3000 prisoners.

The khali‘a’s black flag was captured and sent home to Queen Victoria. The British and Egyptian casualties together were under 500. The European prisoners of the khali‘a found in Omdurman—Charles Neufeld, Joseph Ragnotti, Sister Teresa Grigolini, and some 30 Greeks—were released; and on Sunday the 4th of September the sirdar, with representatives from every regiment, crossed the river to Khartum, where the British and Egyptian flags were hoisted, and a short service held in memory of General Gordon, near the place where he met his death.

The results of the battle of Omdurman were the practical destruction of the khali‘a’s army, the extinction of Mahdism in the Sudan, and the recovery of nearly all the country formerly under Egyptian authority.

The khali‘a fled with a small force to Obeid in Kordofan. The British troops were quickly sent down stream to Cairo, and the sirdar, shortly afterwards created Lord Kitchener of Khartum, was free to turn his attention to the reduction of the country to some sort of order.

He had first, however, to deal with a somewhat serious matter—the arrival of a French expedition at Fashoda, on the White Nile, some 600 m. above Khartum. He started for the north on the 1st of September, with 5 gunboats and 2,450 men of the 3rd Infantry Brigade, and on the 9th reached Fashoda, to find the French Captain Marchand, with 120 Sengalese soldiers, entrenched there and the French flag flying. He arranged with Marchand to leave the political question to be settled by diplomacy, and contested himself with hoisting the British and Egyptian flags to the south of the French flag, and leaving a gunboat and a Sudanese battalion to guard them. He then steamed up the river and established a post at Sobat; and after sending a gunboat up the Bahir-el-Ghamal to establish another post at Meshraer-Rek, he returned to Omdurman.

The French expedition had experienced great difficulties in the swampy region of the Bahir-el-Ghamal, and had reached Fashoda on the 10th of July. It had been attacked by a dervish force on the 29th of August, and was expecting another attack when Kitchener arrived and probably saved it from destruction. The Fashoda incident was the subject of important diplomatic negotiations, which at one time approached an acute phase; but ultimately the French position was found to be untenable, and on the 11th of December Marchand and his men returned to France by the Sobat; Abyssinia and Jibutti. In the following March the spheres of interest of Great Britain and France in the Nile basin were defined by a declaration making an addition to Article IV. of the Niger convention of the previous year.

During the sirdar’s absence from Omdurman Colonel Forster commanded an expedition up the Blue Nile, and by the end of...
September had occupied and garrisoned Wad Medani, Sennar, Karkoj and Roseires. In the meantime Colonel Parsons marched with 1400 men from Kassala on the 7th of September, to capture Gedaref. He found 4000 men under the Amir Saadalla outside the town, and after a desperate fight, in which he lost 50 killed and 80 wounded, defeated them and occupied the town on the 22nd. The dervishes left 500 dead on the field, among whom were four amirs. Having strongly entrenched himself, Parsons beat off, with heavy loss to the dervishes, two impetuous attacks made on the 28th by Ahmed Fedil. But the garrison of Gedaref suffered from severe sickness, and Colonel Collinson was sent to their aid with reinforcements from the Sudan. He steamed up the Blue Nile and the Rahad river to Ain-el-Oweiga, whence he struck across the desert, reaching Gedaref on the 21st of October, to find that Ahmed Fedil had gone south with his force of 5000 men towards Roseires. Colonel Lewis, who was at Karkoj with a small force, moved to Roseires, where he received reinforcements from Omdurman, and on the 26th of December caught Ahmed Fedil's force as it was crossing the Blue Nile at Dakhela, and after a very severe fight cut it up. The dervish loss was 500 killed, while the Egyptians had 24 killed and 118 wounded. Two thousand five hundred fighting men surrendered later, and the rest escaped with Ahmed Fedil to join the khilifa in Kordofan.

On the 25th of January 1899 Colonel Walter Kitchener was despatched by his brother, in command of a flying column of 3000 Egyptian troops and 1700 Friendslies, which had been concentrated at Medani, on the Wadi el Khashi, on the way to some 200 m. above Khartum, to reconnoitre the khilifa's camp at Sherkela, 130 m. west of the river, in the heart of the Baggara country in Kordofan, and if possible to capture it. The position was found to be a strong one, occupied by over 6000 men; and as it was not considered prudent to attack it with an inferior force at such a distance from the river base, the flying column returned. No further attempt was made to interfere with the khilifa in his far-off retreat until towards the end of the year, when, good order having been generally established throughout the rest of the Sudan, it was decided to extend it to Kordofan.

In the autumn of 1899 the khilifa was at Jebel Gedir, a hill in southern Kordofan, about 80 m. from the White Nile, and was contemplating an advance. Lord Kitchener concentrated 8000 men at Kaka, on the river, 350 m. south of Khartum, and moved up north on 20th of October. On arriving there it was ascertained that the khilifa had gone north, and the cavalry and camel corps having reconnoitred Jebel Gedir, the expedition returned. On the 1st November the Amir Ahmed Fedil debouched on the river at El Alub, but retired after finding Colonel Lewis with a force in gunboats. Troops and transport were then concentrated at Faki Kohi, and Colonel Wingate sent with reinforcements from Khartum to take command of the expedition and March to Gedir, where it was anticipated the khilifa would be obliged to halt. A flying column, comprising a squadron of cavalry, a field battery, 6 machine guns, 6 companies of the camel corps, and a brigade of infantry and details, in all 3700 men, under Wingate, left Faki Kohi on the 21st of November. The very next day he encountered Ahmed Fedil at Abu Aadel, drove him from his position with great loss, and captured his camp and a large supply of grain he was conveying to the khilifa. Gedid was reached on the 23rd, and the khilifa was ascertained to be at Om Debretak. Wingate marched at midnight of the 24th, and was resting his troops on high ground in front of the khilifa's position, when at daybreak of the 25th his picquets were driven in and the dervishes attacked. They were repulsed with great slaughter, and Wingate advancing, carried the camp. The khilifa Abdullah el Taasah, unable to rally his men, gathered many of his principal amirs around him, among whom were his sons and brothers, All Wad Helu, Ahmed Fedil, and other well-known leaders, and they met their death unflinchingly from the bullets of the advancing Sudanese infantry. Three thousand men and 29 amirs of importance, including Sheik-eldin, the khilifa's eldest son and intended successor, surrendered. The dervish loss in the two actions was estimated at 1000 killed and wounded, while the Egyptian casualties were only 4 killed and 20 wounded. Thus ended the power of the khilifa and of Mahdism.

On the 10th of January 1900 Osman Digna, who had been so great a supporter of Mahdism in the Eastern Sudan, and had always shown great discretion in securing the safety of his own person, was surrounded and captured at Jebel Warriba, as he was wandering a fugitive among the hills beyond Tokar.

The reconquest of Dongola and the Sudan provinces during the three years from March 1898 to December 1899, considering the enormous extent and difficulties of the country, was achieved at an unprecedentedly small cost, while the main item of expenditure—the railway—remains a permanent benefit to the country. Towards this expense the British government gave a grant-in-aid of £500,000, and the balance was borne by the Egyptian treasury. The railway, delayed by the construction of the bridge over the River Atbara, was opened to the Blue Nile opposite Khartoum from the Atbara, at the end of 1899.

EHRENBERG, CHRISTIAN GOTTFRIED (1795-1876), German naturalist, was born at Deltitzsch in Saxony on the 10th of April 1795. After studying at Leipzig and Berlin, where he took the degree of doctor of medicine in 1818, he was appointed professor of medicine in the university of Berlin (1827). Meanwhile in 1820 he was engaged in a scientific exploration conducted by General von Minutoli in Egypt. They investigated parts of the Libyan desert, the Nile valley and the northern coasts of the Red Sea, where Ehrenberg made a special study of the corals. Subsequently parts of Syria, Arabia and Abyssinia were examined. Some results of these travels and of the important collections that had been made were reported on by Humboldt in 1826; and afterwards Ehrenberg was enabled to bring out two volumes Symbolae physicae (1828-1834), in which many particulars of the mammals, birds, insects, &c., were made public. Other observations were communicated to scientific societies. In 1829 he accompanied Humboldt through eastern Russia to the Chinese frontier. On his return he gave his attention to microscopical researches. These had an important bearing on some of the infusorial earths used for polishing and other economic purposes; they added, moreover, largely to our knowledge of the microscopic organic life of the surface of the earth, mostly especially of the chalk, and of the modern marine and freshwater accumulations. Until Ehrenberg took up the study it was not known that considerable masses of rock were composed of minute forms of animals or plants. He demonstrated also that the phosphorescence of the sea was due to organisms. He continued until late in life to investigate the microscopic organisms of the deep sea and of various geological formations. He died in Berlin on the 27th of June 1876.

EHRENREICHTH, a town of Germany, in the Prussian Rhine province, on the right bank of the Rhine, facing Coblenz. It has a bridge over the river, a railway bridge and a bridge of boats, on the main line of railway Frankfort-on-Main-Cologne. Pop. (including the garrison) 5300. It has an Evangelical and two Roman Catholic churches, a Capuchin monastery, tanneries, soap-works and a considerable trade in wine. Above the town facing the mouth of the Mosel, on a rock 400 ft. high, lies the magnificent fortress of Ehrenbreitstein, considered practically impregnable. The sides towards the Rhine and the south-west are precipitous, and on the south side, on which is the winding approach, strongly defended. The central fort or citadel is flanked by a double line of works with three tiers of casemate batteries. The works towards the north and north-east.
end in a separate outlying fort. The whole forms a part of the system of fortifications which surround Coblenz.

The site of the castle is said to have been occupied by a Roman fort in the time of the emperors Diocletian and Constantine. In the 10th century the castle was held by a noble named Emmerling, from whom it is said to have derived its name. In the 13th century it came into the possession of Archbishop Hillin (de Falletagne) of Trier, who strengthened the defenses in 1153. These were again extended by Archbishop Henry II. (de Fénétrange) in 1286, and by Archbishop John II. of Baden in 1481. In 1513 it was surrendered by the archbishop elector Philip Christopher von Soutern to the French, but was reconquered by the Empire in 1517 and given to the archbishop elector of Cologne. It was restored to the elector of Trier in 1550, but was not strongly fortified until 1672. In 1688 the French bombarded it in vain, but in 1759 they took it and held it till 1762. It was again blockaded in 1795, 1796 and 1797, in vain; but in 1799 they starved it into surrender, and at the peace of Lunéville in 1801, blew it up before evacuating it. At the second peace of Paris the French paid 15,000,000 francs to the Prussian government for its restoration, and from 1816 to 1836 the fortress was reconstructed by General L. A. *Astier (1728-1835).

**EHUD**, in the Bible, a "judge" who delivered Israel from the Moabites (Judg. iii. 12-30). He was sent from Ephraim to bear tribute to the king of Moab, who had crossed over the Jordan and seized the district around Jericho. Being, like the Benjamites, left-handed (cf. xx. 16), he was able to conceal a dagger and strike down the king before his intentions were suspected.

He left, and entered into his chamber and escaped. The men from Mt Ephraim collected under his leadership and by seizing the fords of the Jordan were able to cut off the Moabites. He is called the son of Gerah, a Benjamite, but both Benah and Gerah are tribal names (2 Sam. xvi. 5, 1 Chron. viii. 5, 5 sq.) it has been thought that this notice is not genuine. The tribe of Benjamin rarely appears in the old history of the Hebrews before the time of Saul. See further BENJAMIN; JUDGES.

**EBENHOE*, a town of Germany, in the kingdom of Saxony, near the Mulde, on the borders of Bohemia, 27 m. by rail S.E. of Zwickau. Pop. (1905) 7460. It is a principal seat of the tannour embroidery which was introduced in 1775 by Clara Angermann. It possesses chemical and tobacco manufactories, and tin and iron works. It has also a large cattle market. Eibenstock, together with Schwarzenberg, was acquired by purchase in 1533 by Saxony and was granted municipal rights in the following year.

**EICHBERG, JULIUS** (1824-1893), German musical composer, was born at Düsseldorf on the 13th of June 1824. When he was nineteen he entered the Brussels Conservatoire, where he took first prizes for violin-playing and composition. For eleven years he occupied the post of professor in the Conservatoire of Geneva. In 1857 he went to the United States, staying two years in New York and then proceeding to Boston, where he became director of the orchestra at the Boston Museum. In 1867 he founded the Boston Conservatory of Music. Eichberg published several educational works on music; and his four operettas, *The Doctor of Alcantara, The Rose of Tyrol, The Two Cadis* and *A Night in Rome*, were highly popular. He died in Boston on the 18th of January 1893.

**EICHENDORFF, JOSEPH, FREIHERR VON** (1788-1857). German poet and romance-writer, was born at Lubowitz, near Ratibor, in Silesia, on the 10th of March 1788. He studied law at Halle and Heidelberg from 1805 to 1808. After a visit to Paris he went to Vienna, where he resided until 1813, when he joined the Prussian army as a volunteer in the famous Lützow corps. When peace was concluded in 1815, he left the army, and in the following year he was appointed to a judicial office at Breslau. He subsequently held similar offices at Danzig, Königsberg and Berlin. Retiring from public service in 1844, he lived successively in Danzig, Vienna, Dresden and Berlin. He died at Naisa on the 26th of December 1857.

Eichendorff was one of the most distinguished of the later members of the German romantic school. His genius was essentially lyrical. Thus he is most successful in his shorter romances and dramas, where constructive power is least called for. His first work, written in 1811, was a romance, *Ahnung und Gegenwart* (1813). This was followed at short intervals by several others, among which the foremost place is by general consent assigned to *Aus dem Leben eines Teufelschweines* (1826), which has often been reprinted. Of his dramas may be mentioned *Erscheinung von Romana* (1828); and *Der letzte Helden von Marienburg* (1830), both tragedies; and a comedy, *Die Freier* (1833). He also translated several of Calderon's religious dramas (Geistliche Schaupiele, 1846). It is, however, through his lyrics (Gedichte, first collected 1837) that Eichendorff is best known and beloved, and he is often spoken of as the chief exponent of the romantic movement. No one has given more beautiful expression than he to the poetry of a wandering life; often, again, his lyrics are exquisite word pictures interpreting the mystical meaning of the moods of nature, as in *Nachts*, or the old-time mystery which yet haunts the twilight forests and feudal castles of Germany, as in the dramatic lyric *Waldgespräch oder Auf einer Burg*. Their language is simple and musical, which makes them very suitable for singing, and they have been often set, notably by Schubert and Schuman.

In the latter years of his life Eichendorff published several works on subjects in literary history and criticism such as *Über die ethischen und religiösen Bedeutungen der neuen romanischen Poesie in Deutschland* (1847), Der deutsche Roman des 18. Jahrhunderts in seinem Verhältnis zum Christentum (1851), and Geschichte der poetischen Litteratur Deutschlands (1856), but the value of these works is impaired by the author's reactionary views. His collected works appeared in six volumes, appeared at Leipzig in 1870.

**EICHHORN, JOHANN GOTTFRIED** (1752-1827), German theologian, was born at Dörrenzimmern, in the principality of Hohenlohe-Oehringen, on the 16th of October 1752. He was educated at the state school in Weikersheim, where his father was superintendent, at the gymnasium at Heilbronn and at the university of Göttingen (1770-1774), studying under J. D. Michaelis. In 1774 he received the rectorship of the gymnasium at Ohrdruf, in the duchy of Gotha, and in the following year was made professor of Oriental languages at Jena. On the death of Michaelis in 1788 he was elected professor ordinarius at Göttingen, where he lectured not only on Oriental languages and on the exegesis of the Old and New Testaments, but also on political history. His health was shattered in 1825, but he continued his lectures until attacked by fever on the 14th of June 1827. He died on the 27th of that month. Eichhorn has been called "the founder of modern Old Testament criticism." He first properly recognized its scope and problems, and began many of its most important discussions. "My greatest trouble," he says in the preface to the second edition of his *Einleitung*, "I had to bestow on a hitherto unworked field—on the investigation of the inner nature of the Old Testament with the help of the Higher Criticism (not a new name to any humanist)." His investigations led him to the conclusion that "most of the writings of the Hebrews have passed through several hands." He took for granted that all the so-called supernatural facts relating to the Old and New Testaments were explicable on natural principles. He sought to judge them from the standpoint of the ancient world, and to account for them by the superstitious beliefs which were then generally in vogue. He did not perceive in the biblical books any religious ideas of much importance for modern times; they interested him merely historically and for the light they threw upon antiquity. He regarded the battle against the Old Testament as spurious and secondary, the genuineness of 7 Peter and Jude, denied the Pauline authorship of Timothy and Titus,
and suggested that the canonical gospels were based upon various translations and editions of a primary Aramaic gospel. He did not appreciate as sufficiently as David Strauss and the Tübinger school, which a national theory has to surmount, nor did he support his conclusions by such elaborate discussions as they deemed necessary.

His principal works were—Geschichte des Oschtindischen Handsels vor Mohammed (Gotha, 1775); Allgemeine Bibliothek der biblischen Literatur (10 vols., Leipzig, 1780-1801); Einleitung in das Neue Testament (2 vols., Leipzig, 1780-1801); Einleitung in das Alte Testament (2 vols., Leipzig, 1790-1801); Einleitung in das Neue Testament (2 vols., Leipzig, 1804-1812); Einleitung in die apokryphischen Bücher des Alten Testaments (Göttingen, 1790); Commentarius in apocalyptam Joannem (2 vols., Göttingen, 1797); Die Hebr. Propheten (3 vols., Göttingen, 1808-1813); Geschichte der Cultur und Literatur des neuen Europs (2 vols., Göttingen, 1796-1799); Literargeschichte (1st vol., Göttingen, 1799: 2nd ed. 1813: 2nd vol. 1814): Geschichte der Literatur von ihrem Anfange bis auf die neueste Zeit (5 vols., Göttingen, 1809-1812); Übersicht der Französischen Revolution (2 vols., Göttingen, 1797); Weltgeschichte (3rd ed., 5 vols., Göttingen, 1819-1820); Geschichte der drei letzten Jahrhunderte (3rd ed., 6 vols., Hanover, 1817-1818); Die geschichte des erlauchten Hauses der Welfen (Hanover, 1817).

EICHORN, KARL FRIEDRICH (1781-1845), German jurist, son of the preceding, was born at Jena on the 20th of November 1781. He entered the university of Göttingen in 1797. In 1805 he obtained the professorship of law at Frankfort-on-Oder, holding it till 1811, when he accepted the same chair at Berlin. On the call to arms in 1813 he became a captain of horse, and returned to the war that was raging in the north of Germany. In 1817 he was offered the chair of law at Göttingen, and preferring it to the Berlin professorship, taught there with great success till ill-health compelled him to resign in 1828. His successor in the Berlin chair having died in 1832, he again entered on its duties, but resigned two years afterwards. In 1833 he received an appointment in the ministry of foreign affairs, which, with his labours on many state committees and his legal researches and writings, occupied him till his death, which occurred on the 4th of July 1854. Eichhorn is regarded as one of the principal authorities on German constitutional law. His chief work is Deutsche Staats- und Reichsgeschichte (Göttingen, 1805-1823, 5th ed. 1843-1844). In company with Savigny and J. F. L. Gösch, he founded the Zeitschrift für geschichtliche Rechtswissenschaft. He was the author besides of Einleitung in das deutsche Privatrecht mit Einschluss des Lehrbuchs der Geschicht der Geschichten der evangelischen Kirchengeschichte in Deutschland, 2 Bde. (ib., 1831-1833).

See Schulte, Karl Friedrich Eichhorn, sein Leben und Wirken (1884).

EICHTÄTTL, a town and episcopal see of Germany, in the kingdom of Bavaria, in the deep and romantic valley of the Altmühl, 35 m. S. of Nuremberg, on the railway to Ingolstadt and Munich. Pop. (1865) 7700. The town, with its numerous spires and remains of medieval fortifications, is very picturesque. It has an Evangelical and seven Roman Catholic churches, among the latter the cathedral of St. Wilibald (first bishop of Eichtätt),—with the tomb of the saint and numerous pictures and relics,—the church of St. Walpurga, sister of Wilibald, whose remains rest in the choir, and the Capuchin church, a copy of the Holy Sepulchre. Of its secular buildings the most noticeable are the town hall and the Leuchtenberg palace, once the residence of the prince bishops and later of the dukes of Leuchtenberg (now occupied by the court of justice of the district), with beautiful grounds. The Wilibaldsburg, built on a neighbouring hill in the 14th century by Bishop Bertold of Hohenzeollern, was long the residence of the prince bishops of Eichtätt, and now contains an historical museum. There are an episcopal lyceum, a clerical seminary, a classical and a modern school, and numerous religious communities. The industries of the township include boot making, brewing and the production of lithographic stones.

Eichtätt (Lat. Aureatum or Rubilocus) was originally a Roman station which, after the foundation of the bishopric by Boniface in 745, developed into a considerable town, which was surrounded with walls in 908. The bishops of Eichstätt were princes of the Empire, subject to the spiritual jurisdiction of the archbishops of Mainz, and ruled over considerable territories in the Circle of Franconia. In 1802 the see was secularized and incorporated in Bavaria. In 1817 it was given, with the duchy of Leuchtenberg, as a mediatised domain under the Bavarian crown, by the king of Bavaria to his son-in-law Eugène de Beauharnais, ex-vicecyro of Italy, henceforth styled duke of Leuchtenberg. In 1855 it reverted to the Bavarian crown.

EICHWALD, KARL EDUARD VON (1795-1876), Russian geologist and physician, was born at Miltau in Courland on the 23rd July 1795. He became doctor of medicine and professor of zoology in Kazan in 1823; four years later professor of zoology and comparative anatomy at Vilna; in 1838 professor of zoology, mineralogy and medicine at St. Petersburg; and finally professor of palaeontology in the institute of mines in that city. He travelled much in the Russian empire, and was a keen observer of its natural history and geology. He died at St Petersburg on the 20th of November 1876. His published works include Reise auf dem Caspischen Meer und in den Caucasus, 2 vols. (Stuttgart and Tübingen, 1834-1838); Die Ueberrett Russlands (St Petersburg, 1840-1845); Leithes Rossica, ou paléontologie de la Russie, 3 vols. (Stuttgart, 1852-1868), with Atlases.

EIDER, a river of Prussia, in the province of Schleswig-Holstein. It rises to the south of Kiel, in Lake Redder, flows first north, then west (with wide-sweeping curves), and after a course of 177 m. enters the North Sea at Tönning. It is navigable for about 148 m. through the city of Kiel, and the channel through which it runs in its lower course. Since the reign of Charlemagne, the Eider (originally Αγγέρ Δήρ—Neptune's gate) was known as Romani terminus imperii and was recognized as the boundary of the Empire in 1027 by the emperor Conrad II., the founder of the Salian dynasty. In the controversy arising out of the Schleswig-Holstein Question, which culminated in the war of Austria and Prussia against Denmark in 1864, the Eider gave its name to the "Eider Dannes," the ironclad Danish party which maintained that Schleswig (Sønderjylland, South Jutland) was by nature and historical tradition an integral part of Denmark. The Eider Canal (Eider-Kanal), which was constructed between 1777 and 1784, leaves the Eider at the point where the river turns to the west and enters the Bay of Kiel at Holtenau. It was hampered by six sluices, but was used annually by some 4000 vessels, and until its conversion in 1887-1895 into the navigation for small vessels, it was the only direct connexion between the North Sea and the Baltic.

EIDER (Icelandic, Arður), a large marine duck, the Somateria mollissima of ornithologists, famous for its down, which, from its extreme lightness and elasticity, is in great request for filling bed-coverlets. This bird generically frequents low rocky islets near the coast, and in Iceland and Norway has long been afforded every encouragement and protection, a fine being inflicted for killing it during the breeding-season, or even for firing a gun near its haunts, while artificial nesting-places are in many localities contrived for its further accommodation. From the care thus taken of it in those countries it has become exceedingly tame at its chief resorts, which are strictly regarded as property, and the taking of eggs or down from them, except by authorized persons, is severely punished by law. In appearance the eider is somewhat clumsy, though it flies fast and dives admirably. The female is of a dark reddish-brown colour barred with brownish-black. The adult male in spring is conspicuous by his pied plumage of velvet-black beneath, and white above: a patch of shining sea-green on his head is only seen on close inspection. This plumage he is considered not to acquire until his third year, being when young almost exactly like the female, and it is certain that the birds which have not attained their full dress remain in flocks by themselves without going to the fountain stations. The nest is generally in some convenient corner among large stones, hollowed in the soil, and furnished with a few bits of dry grass, seaweed or seaweed. By the time that the full number of eggs (which rarely if ever exceeds five) is laid the down is added. Generally the eggs and down are
The numerous so-called crater-lakes or mare of the Eifel present several features of interest. They do not, as a rule, lie in true craters at the summit of volcanic cones, but rather in hollows which have been formed by explosions. The most probable group is that of Daun, where the three craters of Gemünden, Weinfeld and Schalkenmehlen have been hollowed out in the Lower Devonian strata. The first of these shows no sign of either lavas or scoriae, but volcanic rocks occur on the margins of the other two. The two largest lakes in the Eifel region, however, are the Laacher See in the hills west of Andernach on the Rhine, and the Pulvermära S.S. of the Daun group, with its shores of peculiar volcanic sand, which also appears in its sandstone beds. The Laacher See is, however, the largest lake in the Eifel region, and its probable depth is 334 ft.

**Eifel Tower.** Erected for the exposition of 1880, the Eifel Tower, in the Champ de Mars, Paris, is by far the highest artificial structure in the world, and its height of 300 metres (984 ft.) surpasses that of the obelisk at Washington by 425 ft., and that of St Paul's cathedral by 350 ft. Its framework is composed essentially of four uprights, which rise from the corners of a square measuring 100 metres on the side; thus the area it covers at its base is nearly 24 acres. These uprights are supported on huge piles of masonry and concrete, the foundations for which were carried down, by the aid of iron caissons and compressed air, to a depth of about 15 metres on the side next the Seine, and about 9 metres on the other side. At first they curve upwards at an angle of 54°; then they gradually become straighter, until they unite in a single shaft rather more than half-way up. The first platform, at a height of 57 metres, has an area of 5860 sq. yds., and is reached either by staircases or lifts. The next, accessible by only one, is 115 metres up, and has an area of 32 sq. yds; while the third, at 276, supports a pavilion capable of holding 500 persons. Nearly 25 metres higher up still is the lantern, with a gallery 5 metres in diameter. The work of building this structure, which is mainly composed of iron lattice-work, was begun on the 28th of January 1887, and the full height was reached on the 13th of March 1889. Besides being one of the sights of Paris, to which visitors resort in order to enjoy the extensive view that can be had from its higher galleries on a clear day, the tower is used to some extent for scientific and semi-scientific purposes; thus meteorological observations are carried on. The engineer under whose direction the tower was constructed was Alexandre Gustave Eiffel (born at Dijon on the 15th of December 1832), who had already had a wide experience in the construction of large metal bridges, and who designed the huge sluices for the Panama Canal, when it was under construction.

**Eifel Hills.** A group of three conical hills, of volcanic origin, in Roxburghshire, Scotland, 2 m. S. by E. of Melrose, about equidistant from Melrose and St Boswells stations on the North British railway. They were once known as Eildes—the Elidunum of Simeon of Durham (fl. 1130)—probably derived from the Gaelic aill, "rock," and dun, "hill;" but the name is also said to be a corruption of the Cymric moelidin, "hill." The northern peak is 1327 ft. high, the central 1385 ft. and the southern 1216 ft. Whether or not the Roman station of Trimo-tium was situated here is matter of controversy. According to General William Roy (1725-1790) Trimontium—so called, according to this theory, from the triple Eildon heights—was Old Melrose; other authorities incline to place the station on the northern shore of the Solway Firth. The Eildons have been the subject of much legendary lore. Michael Scot (1175-1234), acting as a confidante of the Evil One (so the fable runs) left gold and silver, then a single cone, into the three existing peaks. Another legend states that Arthur and his knights sleep in a vault beneath the Eildons. A third legend centres in Thomas of Erceldoune. The Eildon Tree Stone, a large moss-covered boulder, lying on the high road as it bends towards the west within 2 m. of Melrose, marks the spot where the Fairy Queen led him into her realms in the heart of the hills. Other places associated with this legend may still be identified. Hunly Banks, where "true Thomas" lay and watched the queen's approach, is half a mile west of the Eildon Tree Stone, and on the
EILENBURG—EINHARD

western side of the hills is Bogle Burn, a streamlet that feeds the Tweed and probably derives its name from its ghostly visitor. Here, too, is Rhymer's glen, although the name was invented by Sir Walter Scott, who added the hero to his Abbot of Tornay. Bowden, to the south of the hills, was the birthplace of the poets Thomas Aird (1802–1876) and James Thomson, and its parish church contains the burial-place of the dukes of Roxburghe. Eildon Hall is a seat of the dukes of Buccleuch.

EILENBURG, a town of Germany, in the Prussian province of Saxony, on an island formed by the Mulde, 31 m. E. from Halle, at the junction of the railways Halle-Cottbus and Leipzig-Eilenburg. Pop. (1900) 15,148. There are three churches, two Roman Catholic. The industries of the town include the manufacture of chemicals, cloth, quilting, calico, cigars and agricultural implements, bleaching, dyeing, basket-making, carriage-building and trade in cattle. In the neighbourhood is the iron foundry of Erswinhof. Opposite the town, on the steep left bank of the Mulde, is the castle from which it derives its name, the original seat of the noble family of Eulenburg. This castle (illburg) is mentioned in records of the reigns of Henry the Fowler as an important outpost against the Sorbs and Wendas. The town itself, originally called Moldanau, is of great antiquity. It is first mentioned as a town in 981, when it belonged to the house of Wettin and was the chief town of the East Mark. In 1386 it was incorporated in the margraviate of Meissen. In 1815 it passed to Prussia.

See Gundermann, Chronik der Stadt Eilenburg (Eilenburg, 1879).

EINBECK, or Eimbeck, a town of Germany, in the Prussian province of Hanover, on the Ilme, 50 m. by rail S. of Hanover. Pop. (1905) 8709. It is an old-fashioned town with many quaint wooden houses, notable among them the "Northheimhaus," a beautiful specimen of medieval architecture. There are several churches, among them the Alexanderkirche, containing the tombs of the princes of Grubenhagen, and a synagogue. The schools include a Realgymnasium (i.e. predominantly for "modern subjects", technical schools for the advanced study of machine-making, for weaving and for the textile industries, a preparatory training-college and a police school. The industries include brewing, weaving and the manufacture of cloth, carpets, tobacco, sugar, leather-grease, toys and roofing-felt.

Einebeck grew up originally round the monastery of St Alexander (founded 1080), famous for its relic of the True Blood. It is first recorded as a town in 1274, and in the 14th century was the seat of the prince-bishops of the ducal house of Brunswick. The town subsequently joined the Hanseatic League. In the 15th century it became famous for its beer ("Einbecker," whence the familiar "Bock"). In 1540 the Reformation was introduced by Duke Philip of Brunswick-Salzdetlbergen (d. 1551), with the death of whose son Philip II. (1596) the Grubenhagen line became extinct. In 1636, during the Thirty Years' War, Einbeck was taken by Pappenheim and in October 1643 by Piccolomini. In 1643 it was evacuated by the Imperialists. In 1797 its walls were razed by the French.

See H. L. Harland, Gesch. der Stadt Einbeck, 2 Bde. (Einbeck, 1854–1859; abridgment, ib. 1881).

EINHOFEN, a town in the province of North Brabant, Holland, and a railway junction 8 m. by rail W. by S. of Helmond. Pop. (1900) 4730. Like Tilburg and Helmond it has developed in modern times into a flourishing industrial centre, having linen, woollen, cotton, tobacco and cigar, matches, &c., factories and several breweries.

EINHARD (c. 770–840), the friend and biographer of Charlemagne; he is also called Einhartus, Ainhardus or Heinhardus, in some of the early manuscripts. About the 10th century the name was altered into Agenardus, and then to Eginhardus, or Eginhartus, but, although these variations were largely used in the English and French languages, the form Einhardus, or Einhartus, is unquestionably the right one.

At the statement of Walfrid Strabo, Einhard was born in the district which is watered by the river Main, and his birth is fixed at about 770. His parents were of noble birth, and were probably named Einhart and Engrifrit; and their son was educated in the monastery of Fulda, where he was certainly residing in 788 and in 791. Owing to his intelligence and capacity he was sent by his abbott, Walfrid, to the court of Charlemagne by abbot Baugulf; and he soon became very intimate with the king and his family, and undertook various important duties, one writer calling him dominicus palatii regulus. He was a member of the group of scholars who gathered around Charlemagne, and was entrusted with the charge of the public buildings, receiving, according to a fashion then prevalent, the scriptural name of Bezaleel (Exodus xxxi. 2), and was also 30-30-35 owing to his artistic skill. It has been supposed that he was responsible for the erection of the basilica at Aix-la-Chapelle, where he resided with the emperor, and the other buildings mentioned in chapter xviii. of his Vita Karoli Magni, but there is no express statement to this effect. In 806 Charlemagne sent him to Rome to obtain the signature of Pope Leo III. to a will which he had made concerning the division of his empire; and it was possibly owing to Einhard's influence that in 813, after the death of his two elder sons, the emperor made his remaining son, Louis, a partner with himself in the imperial dignity. When Louis became sole emperor in 814 he retained his father's minister in his former position; then in 817 made him tutor to his son, Lothair, afterwards the emperor Lothair I.; and showed him many other marks of favour. Einhard married Emma, or Imma, a sister of Bernhardus, bishop of Worms, and a tradition of the 12th century represented this lady as a daughter of Charlemagne, and invented a romantic story with regard to the courtesan which deserves to be noticed as it first calls "fili" and "mi nate," but, as Vusin is not mentioned in documents in which his interests as Einhard's son would have been concerned, it is possible that he was only a young man in whom he took a special interest. In January 815 the emperor Louis I. bestowed on Einhard and his wife the domains of Michelstadt and Mulinheim in the Odenwald, and in the charter conveying these lands he is called simply Einhardus, but, in a document dated the 2nd of June of the same year, he is referred to as abbot. After this time he is mentioned as head of several monasteries: St Peter, Mount Blaind and St Bavon at Ghent, St Servais at Maastricht, St Cloud near Paris, and Fontenelle near Rouen, and he also had charge of the church of St John the Baptist at Pavia.

During the quarrels which took place between Louis I. and his sons, in consequence of the emperor's second marriage, Einhard's efforts were directed to making peace, but after a time he grew tired of the troubles and intrigues of court life. In 818 he had given his estate at Michelstadt to the abbey of Lorsch, but he retained Mulinheim, where about 827 he founded an abbey and erected a church, to which he transported some relics of St Peter and St Marcellinus, which he had procured from Rome. To Mulinheim, which was afterwards called Seligenstadt, he finally retired in 830. His wife, who had been his constant helper, and whom he had not put away on becoming an abbot, died in 836, and after receiving a visit from the emperor, Einhard died on the 14th of March 840. He was buried at Seligenstadt, and his epitaph was written by Hrabanus Maurus. Einhard
EINHORN—EISENACH 135

was a man of very short stature, a feature on which Alcuin wrote an epigram. Consequently he was called Nardusius, a diminutive form of Einhardus, and his great industry and activity caused him to be likened to an ant. He was also a man of learning and culture. Reaping the benefits of the revival of learning brought about by Charlemagne, he was on intimate terms with Alcuin, was well versed in Latin literature, and knew some Greek. His most famous work is his Vita Karoli Magni, to which a prologue was added by Walfrid Strabo. Written in imitation of the De vita beati Pauli by Eucherius, this is the best known and fullest account of the life of Charlemagne, and could only have been written by one who was very intimate with the emperor and his court. It is, moreover, a work of some artistic merit, although not free from inaccuracies. It was written before 821, and having been very popular during the middle ages, was first printed at Cologne in 1521. G. H. Pertz collated more than sixty manuscripts for his edition of 1829, and others have since come to light. Other works by Einhard are: Epistolae, which are of considerable importance for the history of the times; Historia translationis beatorum Christi martyrum Marcellini et Petri, which gives a curious account of how the bones of these martyrs were stolen and conveyed to Seligenstadt, and what miracles they wrought; and De adoranda cruce, a treatise which has only recently come to light, and which has been published by E. Dümmler in the Neues Archiv der Gesellschaft für ältere deutsche Geschichtskunde, Band xi. (Hanover, 1886). It has been asserted that it is the only other extant work of Einhard on the history of the Church, as he was especially of the annals of Lorsch (Annales Lorsiacenses majores), and of the annals of Fulda (Annales Fuldenses). Much discussion has taken place on this question, and several of the most eminent of German historians, Ranke among them, have taken part therein, but no certain decision has been reached.

The literature on Einhard is very extensive, as nearly all those who deal with Charlemagne, early German and early French literature, treat of him. Editions of his works are by A. Teulet, Einhardi omnia quae extant opera (Paris, 1840–1843), with a French translation; P. Jaffe, in the Bibliotheca rerum Germanicarum, Band iv. (Berlin, 1867); G. H. Pertz in the Monumenta Germaniae historica, Bande i. and ii. (Hanover, 1826–1829), and J. P. Migne in the Patrologia Latina, tomes 97 and 104 (Paris, 1866). The Vita Karoli Magni, edited by G. H. Pertz and G. Waite, has been published separately (Hanover, 1880). Among the various translations of the Vita may be mentioned an English one by W. Glaister (London, 1877) and a German one by O. Abetz (Leipzig, 1916). For a complete bibliography of Einhard, see P. Potthast, Bibliotheca rerum germanicarum, Band x. (Berlin, 1896), and W. Wattenbach, Deutslands Geschichtsquellen, Band i. (Berlin, 1904). (A. W. H.)

EINHORN, DAVID (1809–1879), leader of the Jewish reform movement in the United States of America, was born in Bavaria. He was a supporter of the principles of Abraham Geiger (q.v.), and while still in Germany advocated the introduction of prayers in the vernacular, the exclusion of nationalistic hopes from the synagogue service, and other ritual modifications. In 1853 he migrated to America, where he became the acknowledged leader of reform, and laid the foundation of the regime under which the mass of American Jews (except the newly arrived Russians) now worship. In 1858 he published his revised prayer book, which has formed the model for all subsequent revisions. In 1861 he strongly supported the anti-slavery party, and was forced to leave Baltimore where he then ministered. He continued his work first in Philadelphia and later in New York. (A. A. S.)

Eisenach is the most populous city of the Territory of Schwyz. It is built on the right bank of the Alpbach (an affluent of the Sihl), at a height of 908 ft. above the sea-level on a rather bare moorland, and by rail is 25 m. S.E. of Zürich, or by a roundabout railway route about 38 m. north of Schwyz, with which it communicates directly over the Hacken Pass (4654 ft.) or the Holzegg Pass (4516 ft.). In 1900 the population was 8496, all (save 75) Romanists and all (save 112) German-speaking. The town is located on the great Benedictine abbey that rises slightly above it to the east. Close to its present site Meinrad, a hermit, was murdered in 861 by two robbers, whose crime was made known by Meinrad's two pet ravens. Early in the 10th century Benno, a hermit, rebuilt the holy man's cell, but the abbey proper was not founded till about 925, the church having been consecrated (it is said by Christ Himself) in 948. In 1274 the dignity of a prince of the Holy Roman Empire was confirmed by the emperor to the reigning abbot. Originally under the protection of the counts of Rapperswil (to which town on the lake of Zürich the old pilgrims' way still leads over the Etzel Pass, 3246 ft., with its chapel and inn), this position passed by marriage with their heiress in 1235 to the Laufenburg in lower Switzerland, and from 1366 was permanently occupied by Schwyz. A black wooden image of the Virgin and the name of St Meinrad caused the throns of pilgrims to resort to Einsiedeln in the middle ages, and even now it is much frequented, particularly about the 14th of September. The existing buildings date from the 18th century only, while the treasury and the library still contain many precious objects, despite the sack by the French in 1798. There are now about 100 fully professed monks, who direct several educational institutions. The Black Virgin has a special chapel in the stately church. Zwingli was the parish priest of Einsiedeln 1516–1518 (before he became a Protestant), while near the town Paraclesus (1493–1541), the celebrated philosopher, was born.

See Father O. Ringholts, Geschichte d. förstl. Benediktinerklost. Einsiedeln, vol. i. (to 1526), (Einsiedeln, 1904). (W. A. B. C.)

EISENACH, a town of Germany, second capital of the granducy of Saxe-Weimar-Eisenach, lies at the north-west foot of the Thuringian forest, on the Fulda, and is separated from the Fulda by the Horsel, 32 m. by rail W. from Erfurt. Pop. (1905) 35,723. The town mainly consists of a long street, running from east to west. Off this are the market square, containing the granducal palace, built in 1742, where the duchess Hélène of Orleans long resided, the town-hall, and the late Gothic St Georgenkirche; and the square on which stands the Nikolakirche, a fine Romanesque building, built about 1150 and restored in 1887. On the south side of the town is the Klemens, a small castle dating from 1260; the Lutherhaus, in which the reformer stayed with the Cotta family in 1498; the house in which Sebastian Bach was born, and that (now a museum) in which Frhr. Reuter lived (1863–1874). There are monuments to the two former in the town, while the resting-place of the latter in the cemetery is marked by a less pretentious memorial. Eisenach has a school of forestry, a school of design, a classical school (Gymnasium) and modern school (Realschule), a deaf and dumb school, a teachers' seminary, a theatre and a Wagner museum. The most important industries of the town are worsted-spinning, carriage and wagon building, and the making of colours and pottery. Among others are the manufacture of cigars, cement pipes, iron-ware and machines, alabaster ware, shoes, leather, &c., cabinet-making, brewing, granite quarrying and working, tile-making, and saw- and corn-milling.

The natural beauty of its surroundings and the extensive forests of the district have of late years attracted many summer residents. Magnificently situated on a precipitous hill, 600 ft. above the town to the south, is the historic Wartburg (q.v.), the ancient castle of the landgraves of Thuringia, famous as the scene of the contest of Minnesingers immortalized in Wagner's Tannhäuser, and as the place where Luther, on his return from the diet of Worms in 1521, was kept in hiding and made his translation of the Bible. On a high rock adjacent to the Wartburg are the ruins of the castle of Müdelstein.

Eisenach (Eisenacum) was founded in 1070 by Louis II. the Springer, landgrave of Thuringia, and its history during the middle ages was closely bound up with that of the Wartburg, the seat of the landgraves. The Klemens, mentioned above, was built by Sophia (d. 1284), daughter of the landgrave Louis IV., and wife of Duke Henry II. of Brabant, to defend the town against Henry III., margrave of Meissen, during the succession war that followed the extinction of the line of the Thuringian landgraves in 1247. The principality of Eisenach fell to the Saxon house of Wettin in 1445, and in the partition of 1485 formed part of the territories given to the Ernestine line. It was a separate Saxon duchy from 1596 to 1628, from 1640
to 1644, and again from 1662 to 1741, when it finally fell to Saxo-
Weimar. The town of Eisenach, by reason of its associations,
has been a favourite centre for the religious propaganda
of Evangelical Germany, and since 1852 it has been the scene of
the annual conference of the German Evangelical Church, known
as the Eisenach conference.

Duschatz, Bevölkerung (Leipzig, 1903), and further references in U.
Chevalier, "Répertoire des sources," &c., Topo-bibliogr. (Mont-
béliard, 1894-1899), s.v.

EISENBERG (Isenberg), a town of Germany, in the duchy of
Saxe-Altenburg, on a plateau between the rivers Saale and
Elster, 20 m. S.W. from Zeitz, and connected with the railway
Leipzig-Gera by a branch to Cossen. Pop. (1905) 8824. It
possesses an old castle, several churches, and monuments to
Duke Christian of Saxe-Eisenberg (d. 1707), Bismarck, and the
philosopher Karl Christian Friedrich Krause (q.v.). Its principal
industries are weaving, and the manufacture of machines,
ovens, furniture, pianos, porcelain and sausages.

See Back, Chronik der Stadt und des Amtes Eisenberg (Eisenb., 1843).

EISNERZ ("Iron ore"), a market-place and old mining
town in Styria, Austria, 68 m. N.W. of Graz by rail. Pop.
(1900) 6404. It is situated in a deep valley, dominated on the
east by the Paffenstein (6140 ft.), on the west by the Kaiser-
schild (6850 ft.), and on the south by the Erzberg (9300 ft.). It
has an interesting example of a medieval fortified church, a
Gothic edifice founded by Rudolph of Habsburg in the 13th
century and rebuilt in the 16th. The Erzberg or Ore Mountain
furnishes such rich ore that it is quarried in the open air like
stone, in the summer months. There is documentary evidence
of the mines having been worked as far back as the 12th century.
They afford employment to two or three thousand hands in
summer and about half as many in winter, and yield some
800,000 tons of iron per annum. Eisner is connected with the
mines by the Erzberg railway, a bold piece of engineering, 24
m. long, constructed on the Abt's track-and-pinion system.
It passes through some beautiful scenery, and descends to
Vorderberg (pop. 3111), an important centre of the iron trade
situated on the south side of the Erzberg. Eisnerz possesses,
in addition, twenty-five furnaces, which produce iron, and
particularly steel, of exceptional excellence. A few miles to the
N.W. of Eisnerz lies the castle of Leopoldstein, and near it the
beautiful Leopoldsteiner Lake. This lake, with its dark green
water, situated at an altitude of 2028 ft., and surrounded on all
sides by high peaks, is not big, but is very deep, having a depth
of 320 ft.

EISELEN (Lat. Iselbia), a town of Germany, in the Prussian
province of Saxony, 24 m. W. by N. from Halle, on the railway
to Nordhausen and Cassel. Pop. (1905) 25,808. It is divided
into an old and a new town (Alstadt and Neustadt). Among
its principal buildings are the church of St Andrew (Andraskirche),
which contains numerous monuments of the counts of Mansfeld;
the church of St Peter and St Paul (Peter-Paulskirche),
containing the font in which Luther was baptized; the royal
gymnasium (classical school), founded by Luther shortly before
his death in 1546; and the hospital. Eisleben is celebrated
as the place where Luther was born and died. The house in
which he was born was burned in 1689, but was rebuilt in 1893
as a folkschool for orphans. This school fell into decay under
the régime of the kingdom of Westphalia, but was restored in
1817 by King Frederick William III. of Prussia, who, in 1819,
transferred it to a new building behind the old house. The
house in which Luther died was restored towards the end of the
19th century, and his death chamber is still preserved. A
bronze statue of Luther by Rudolf Siemering (1835-1902) was
unveiled in 1883. Eisleben has long been the centre of an
important mining district (Luther was a miner's son), the
principal products being silver, copper, and iron. It possesses smelting
works and a school of mining.

The earliest record of Eisleben is dated 974. In 1045, at
which time it belonged to the counts of Mansfeld, it received
the right to hold markets, coin money, and levy tolls. From
1531 to 1710 it was the seat of the cadet line of the counts
of Mansfeld-Eisleben. After the extinction of the main line
of the counts of Mansfeld, Eisleben fell to Saxony, and, in
the partition of Saxony by the congress of Vienna in 1815, was
assigned to Prussia.

Jahrhunderts (Halle, 1875). Chronik des Eislebener Stadtschen,
chronik aus den Jahren 1550-1718, edited from the original, with
notes by Grosse and Sommer (Eisleben, 1882).

EISTEDDFOD (plural Eisteddfoeddau), the national bardic
congress of Wales, the objects which are to encourage bardism
and the general literature of the Welsh, to maintain
the Welsh language and customs of the country, and to foster
and cultivate a patriotic spirit amongst the people. This institution,
so peculiar to Wales, is of very ancient origin.1 The term
Eisteddfod, however, which means "a session" or "sitting,"
was probably not applied to bardic congresses before the 13th
century.
The Eisteddfod in its present character appears to have
originated in the time of Owain ap Maxen Wledig, who at the
close of the 4th century was elected to the chief sovereignty
of the Britons on the departure of the Romans. It was at this
time, or soon afterwards, that the laws and usages of the Gorsedd
were codified and remodelled, and its motto of "Y gwr yn erbyn
y byd" (The truth against the world) given to it. "Chairs" (with
which the Eisteddfod as a national institution is now
inseparably connected) were also established, or rather perhaps
invented, about the same time. The chair was a kind of
convention where disciples were trained, and bardic matters
discussed preparatory to the great Gorsedd, each chair having
a distinctive motto. There are now existing four chairs in Wales,—
namely, the "royal" chair of Powys, whose motto is "A laddo
a leddir" (He that slayeth shall be slain); that of Gwen and
Glamorgan, whose motto is "Dw a phob dafon" (God and all
goodness); that of Dyfed, whose motto is "Calon wrth galon"
(Heart with heart); and that of Gwynedd, or North Wales, whose
motto is "Iesu," or "O Iesu na'd gamawth" (Jesus, or Oh
Iesus suffer not iniquity).

The first Eisteddfod of which any account seems to have
descended to us was one held on the banks of the Conway in
the 6th century, under the auspices of Maelgwn Gwynedd, prince
of North Wales. Maelgwyn on this occasion, in order to prove
the superiority of vocal song over instrumental music, is
recorded to have offered a reward to such bards and minstrels as
should swim over the Conway. There were several competitors,
but on the wall on the opposite shore the harpers found themselves
unable to play owing to the injury their harps had sustained
from the water, while the bards were in as good tune as ever.
King Cadwaladr also presided at an Eisteddfod about the
middle of the 7th century.

Griffith ap Cynan, prince of North Wales, who had been born
in Ireland, brought with him from that country many Irish
musicians, who greatly improved the music of Wales. During
his long reign of 56 years he offered great encouragement to
bards, harpers and minstrels, and framed a code of laws for their
better regulation. He held an Eisteddfod about the beginning
of the 12th century at Caerwys in Flintshire, "to which there
repaired all the musicians of Wales, and some also from England
and Scotland." For many years afterwards the Eisteddfod
appears to have been held triennially, and to have enforced the
rigid observance of the enactments of Griffith ap Cynan.
The places at which it was generally held were Aberystwyth, formerly
the royal seat of the princes of North Wales; Dynevor, the
royal castle of the princes of South Wales; and Mathrafal,
the royal palace of the princes of Powys; and in later times

1 According to the Welsh Triads and other historical records, the
Gorsedd or assembly (an essential part of the modern Eisteddfod,
from which indeed the latter sprang) is as old at least as the time of
the Druids. The son of Erychty, the son of Ebechm, the son of
Preudain, the son of Peddar before the Christian era. Upon the
destruction of the political ascendency of the Druids, the Gorsedd lost its political importance, though it
seems to have long afterwards retained its institutional character as
the medium for preserving the laws, doctrines and traditions of
bardism.
Caerwys in Flintshire received that honourable distinction, it having been the princely residence of Llewelyn the Last. Some of these Eisteddfodau were conducted in a style of great magnificence, under the patronage of the native princes. At Christmas 1107 Cadwgan, the son of Bleddyn ap Cyngynf, prince of Powys, held an Eisteddfod in Cardigan Castle, to which he invited the bards, harpers and minstrels, "the best to be found in all Wales"; and "he gave them chairs and subjects of oratory according to the custom of the feasts of King Arthur." In 1176 Rhys ab Gruffydd, prince of South Wales, held an Eisteddfod in the same castle on a scale of still greater magnificence, it having been proclaimed, we are told, a year before it took place, "over Wales, England, Scotland, Ireland and many other countries."

On the annexation of Wales to England, Edward I. deemed it politic to sanction the bardic Eisteddfod by his famous statute of Rhuddlan. In the reign of Edward III. Haf Haelu, a South Wales chieflain, held one at his mansion. Another was held in 1451, with the permission of the king, by Griffith ab Nicholas at Carmarthen, in princely style, where Dafydd ab Edmund, an eminent poet, signified himself by his wonderful powers of versification in the Welsh metres, and whence "he carried home on his shoulders the silver chair" which he had fairly won. Several Eisteddfodau, were held, one at least by royal mandate, in the reign of Henry VII. In 1553 one was held at Caerwys before the chamberlain of North Wales and others by virtue of a commission issued by Henry VIII. In the course of time, through relaxation of bardic discipline, the profession was assumed by unqualified persons, to the great detriment of the regular bards. Accordingly in 1567 Queen Elizabeth issued a commission for holding an Eisteddfod at Caerwys in the following year, which was duly held, when degrees were conferred on 55 candidates, including 20 harpers. From the terms of the royal proclamation we find that it was then customary to bestow "a silver harp" on the chief of the faculty of musicians, as it had been usual to reward the chief bard with a "silver chair." This was the last Eisteddfod appointed by royal commission, but several others of some importance were held during the 16th and 17th centuries, under the patronage of the earl of Pembroke, Sir Richard Neville, and other influential persons. Amongst these the last of any particular note was one held in Bwber Castle, Glamorgan, by Sir Richard Basset in 1657.

During the succeeding 130 years Welsh nationality was at its lowest ebb, and no general Eisteddfod on a large scale appears to have been held until 1819, though some small ones were held under the auspices of the Gwyneddigion Society, established in 1777,—the most important being those at Corwen (1780), St Asaph (1790) and Caerwys (1798).

At the close of the Napoleonic wars, however, there was a general revival of Welsh nationality, and numerous Welsh literary societies were established throughout Wales, and in the principal English towns. A large Eisteddfod was held under distinguished patronage at Carmarthen in 1819, and from that time to the present they have been held (together with numerous local Eisteddfodau), almost without interruption, annually. The Eisteddfod at Llangollen in 1858 is memorable for its archaic character, and the attempts then made to revive the ancient ceremonies, and restore the ancient vestments of druids, harps and swords.

To constitute a provincial Eisteddfod it is necessary that it should be proclaimed by a graduated bard of a Gorsedd a year and a day before it takes place. A local one may be held without such a proclamation. A provincial Eisteddfod generally lasts three, sometimes four days. A president and a conductor are appointed for each day. The proceedings commence with a Gorsedd meeting, opened with sound of trumpet and other ceremonies, the candidates proceeding forward and receive bardic degrees after satisfying the presiding bard as to their fitness. At the subsequent meetings the president gives a brief address; the bards follow with poetical addresses; adjudications are made, and prizes and medals with suitable devices are given to the successful competitors for poetical, musical and prose compositions, for the best choral and solo singing, and singing with the harp or "Pennilion singing" as it is called, for the best playing on the harp or stringed or wind instruments, as well as occasionally for the best specimens of handicraft and art. In the evening of each day a concert is given, generally attended by very large numbers. The great day of the Eisteddfod is the "chair" day—usually the third or last day—the grand event of the Eisteddfod being the adjudication on the chair subject, and the chaining and investiture of the fortunate winner. This is the greatest object of a Welsh bard’s ambition. The ceremony is an imposing one, and is performed with sound of trumpet. (See also the articles BARD, CELT: Celtic Literature, and WALES.)

EJECTMENT (Lat. e, out, and jacere, to throw), in English law, an action for the recovery of the possession of land, together with damages for the wrongful withholding thereof. In the old classifications of actions, as real or personal, this was known as a mixed action, because its object was twofold, viz. to recover both the real and personal damages. It should be noted that the term “ejectment” applies in law to distinct classes of proceedings—ejectments as between rival claimants to land, and ejectments as between those who hold, or have held, the relation of landlord and tenant. Under the Rules of the Supreme Court, actions in England for the recovery of land are commenced and proceed in the same manner as ordinary actions. But the historical interest attaching to the action of ejectment is so great as to render some mention of it necessary.

The form of the action as it prevailed in the English courts down to the Common Law Procedure Act 1852 was a series of fictitious, among the most remarkable to be found in the entire body of English law. A, the person claiming title to land, delivered to B, the person in possession, a declaration in ejectment in which C and D, fictitious persons, were plaintiff and defendant. C stated that A had devised the land to him for a term of years, and that he had been ousted by D. A notice signed by D informed B of the proceedings, and A was to apply to be made defendant in D’s place, as he, D, having no title, did not intend to defend the suit. If B did not so apply, judgment was given against D, and possession of the lands was given to A. But if B did apply, the Court allowed him to defend the action only on condition that he admitted the three fictitious averments—the lease, the entry and the ouster—which, together with title, were the four things necessary to maintain an action of ejectment. This having been arranged the action proceeded, B being made defendant instead of D. The names used for the fictitious parties were John Doe, plaintiff, and Richard Roe, defendant, who was called "the casual ejector."

The explanation of these mysterious fictions is this. The writ de ejectione formae was invented about the beginning of the reign of Edward III. as a remedy to a leesee for years who had been ousted of his term. It was a writ of trespass, and carried damages, but in the time of Henry VII., if not before that date, the courts of common law added thereto a species of remedy neither warranted by the original writ nor demanded by the declaration, viz. a judgment to recover so much of the term as was still to run, and a writ of possession thereupon. The next step was to extend the remedy—limited originally to leaseholds—to cases of disputed title to freeholds. This was done indirectly by the claimant entering on the land and there making a lease for a term of years to another person; for it was only a term that could be recovered by the action, and to create a term must be actual possession in the granter. The lessee remained on the land, and the next person who entered even by chance was accounted an ejector of the leesee, who then served upon him a writ of trespass and ejectment. The case then went to trial as on a 1

1 According to Jones’s Bardic Remains, “To sing ‘Pennilion’ with a Welsh harp is not so easily accomplished as may be imagined. The singer is obliged to follow the harper, who may change the tune, even as variations ad libitum, whilst the harper includes the harmonies; and end precisely with the strain. The singer does not commence with the harper, but takes the strain up at the second, third or fourth bar, as best suits the ‘Pennilion’ he intends to sing. . . .” considered the best singers who can adapt different metres to one melody, and who are acquainted with the twenty-four measures according to the bardic laws and rules of composition.”
common action of trespass; and the claimant's title, being the real foundation of the lessee's right, was thus indirectly determined. These proceedings might take place without the knowledge of the person really in possession; and to prevent the abuse of the action a rule was laid down that the plaintiff in ejectment must give notice of its bringing to the party in possession, or it might then come in and defend the action. When the action came into general use as a mode of trying the title to freeholds, the actual entry, lease and ouster which were necessary to found the action were attended with much inconvenience, and accordingly Lord Chief Justice Rolle during the Protectorate (c. 1657) substituted for them the fictitious averments already described.

The action of ejectment is now only a curiosity of legal history. Its fictitious suitors were swept away by the Common Law Procedure Act of 1852. A form of writ was prescribed, in which the person in possession of the disputed premises by name and all persons entitled to defend the possession were informed that the plaintiff claimed to be entitled to possession, and required to appear in court to defend the possession of the property or such part of it as they should think fit. In the form of the writ and in some other respects ejectment still differed from other actions. But, as already mentioned, it has now been assimilated (under the name of action for the recovery of lands) to ordinary actions by the Rules of the Supreme Court. It is commenced by writ of summons, and—subject to the rules as to summary judgments (s. inf.)—proceeds along the usual course of pleadings and trial to judgment; but is subject to one special rule, viz: that except by leave of the Court or a judge the only claims which may be joined with one for recovery of land are claims in respect of arrears of rent or double value for holding over, or mean rents (i.e. the value of the land during the period of illegal possession), or damages for breach of a contract under which the premises are held or for any wrong or injury to the premises claimed (R.S.C., O. xviii. r. 2). These claims were formerly recoverable by an independent action.

With regard to actions for the recovery of land—apart from the relationship of landlord and tenant—the only point that need be noted is the presumption of law in favour of the actual possessor of the land in dispute. Where the action is brought by a landlord against his tenant, there is of course no presumption against the landlord's title arising from the tenant's possession. By the Common Law Procedure Act 1852 (ss. 210-212) special provision was made for the prompt recovery of demised premises where half a year's rent was in arrear and the landlord was entitled to re-enter for non-payment. These provisions are still in force, but advantage is now more generally taken of the summary judgment procedure contained in the Rules of the Supreme Court (Order 3, r. 6). This procedure may be adopted when (a) the tenant's term has expired, (b) or has been duly determined by notice to quit, or (c) has become liable to forfeiture for non-payment of rent, and applies not only to the tenant but to persons claiming under him. The writ is specially endorsed with the plaintiff's claim to recover the land with or without rent or mesne profits, and summary judgment obtained if no substantial defence is disclosed. Where an action to recover land is brought against the tenant by a person claiming adversely to the landlord, the tenant is bound, under penalty of forfeiting the value of three years' improved or rack rent of the premises, to give notice to the landlord in order that he may appear and defend his title. Actions for the recovery of land, other than land belonging to spiritual corporations and to the crown, are barred in 12 years (Real Property Limitation Acts 1853 (c. 39) and 1874 (c. 1)). A landlord can recover possession in the county court (1) by an action for the recovery of possession, where neither the value of the premises nor the rent exceeds £100 a year, and the tenant is holding over (County Courts Acts of 1888, s. 138, and 1903, s. 3); (ii) by "an action of ejectment," where (a) the value or rent of the premises does not exceed £100, (b) half a year's rent is in arrear, and (c) no sufficient distress (see RENT) is to be found on the premises (Act of 1888, s. 139; Act of 1903, s. 3; County Court Rules 1903, Ord. v. rule 3). Where a tenant at a rent not exceeding £20 a year of premises at will, or for a term not exceeding 7 years, refuses nor neglects, on the determination or expiration of his interest, to deliver up possession, such possession may be recovered by proceedings before justices under the Small Tenements Recovery Act 1838, an enactment which has been extended to the recovery of allotments under the Dispersal for Rent Act 1777, and the Deserted Tenements Act 1817, a landlord can have himself put by the order of two justices into premises deserted by the tenant where half a year's rent is owing and no sufficient distress can be found.

In Ireland, the practice with regard to the recovery of land is regulated by the Rules of the Supreme Court 1891, made under the Judicature (Ireland) Act 1877; and resembles that of England. Possession may be recovered summarily by a special indorsement of the writ, as in England; and there are analogous provisions with regard to the recovery of premises (see Land Act, 1860 ss. 84 and 89). The law with regard to the ejectment or eviction of tenants is consolidated by the Land Act 1860. (See ss. 52-66, 68-71, and further under LANDLORD AND TENANT.)

In Scotland, the recovery of land is effected by an action of "removing" or summary ejection. In the case of a tenant without title, or a title merely precarious, no warning is needed. A summary process of removing from small holdings is provided for by Sheriff Courts (Scotland) Acts 1838 and 1851.

In the United States, the old English action of ejectment was adopted to a very limited extent, and where it was so adopted has often been superseded, as in Connecticut, by a single action for all cases of ouster, disesain or ejectment. In this action, known as an action of disesain or ejectment, both possession of the land and damages may be recovered. In some of the states a tenant against whom an action of ejectment is brought by a stranger is bound under a penalty, as in England, to give notice of the claim to the landlord in order that he may appear and defend his title.

In French law the landlord's claim for rent is fairly secured by the hypothec, and by summary powers which exist for the seizure of the effects of defaulting tenants. Eviction or annulment of a lease can only be obtained through the judicial tribunals. The Civil Code deals with the position of a tenant in case of the sale of the property leased. If the lease is by authentic act (acte authentique) or has an ascertained date, the purchaser cannot evict the tenant unless a right to do so was reserved on the lease (art. 1743), and then only on payment of an indemnity (arts. 1744-1745). If the lease is not by authentic act, or has not the ascertained date, the purchaser is not liable for indemnity (art. 1750). The tenant of rural lands is bound to give the landlord notice of acts of usurpation (art. 1768).

There are analogous provisions in the Civil Codes of Belgium (arts. 1743 et seq.), Holland (arts. 1613, 1614), Portugal (art. 1572); and see the German Civil Code (arts. 533 et seq.). In many of the colonies there are statutory provisions for the recovery of land or premises on the lines of English law (cf. Ontario, Rev. Stats. 1897, c. 170, ss. 19 et seq.; Manitoba, Rev. Stats. 1902, c. 1903). In others (e.g. New Zealand, Act. No. 55 of 1893, ss. 175-187; British Columbia, Revised Statutes, 1897, c. 182; Cyprus, Ord. 15 of 1895) there has been legislation similar to the Small Tenements Recovery Act 1838.

EKATERINBURG, a town of Russia, in the government of Perm, 312 m. by rail S.E. of the town of Perm, on the Kast River, near the E. foot of the Urals Mountains, in 58° 49' N. and
EKATERINOJAR—EKHOF

60° 35' E., at an altitude of 800 ft. above sea-level. It is the most important town of the Urals. Pop. (1860) 19,830; (1897) 55,488. The streets are broad and regular, and several of the houses of palatial proportions. In 1834 Ekaterinburg was made the see of a suffragan bishop of the Orthodox Greek Church. The church of the Holy Epiphany, Ekaterinoslav, is the most ancient of the Urals, and that of the Epiphany, in 1774—and a museum of natural history, opened in 1835. Ekaterinburg is the seat of the central mining administration of the Ural region, and has a chemical laboratory for the assay of gold, a mining school, the Ural Society of Naturalists, and a magnetic and meteorological observatory. Besides the government mint for copper coinage, which dates from 1735, the government engineering works, and the imperial factory for the cutting and polishing of malachite, jasper, marble, porphyry and other ornamental stones, the industrial establishments comprise candle, paper, soap and machinery works, flour and woolen mills, and tanneries. There is a lively trade in cattle, cereals, iron, woolen and silk goods, and colonial products; and two important fairs are held annually. Nearly forty gold and platinum mines, over thirty iron-works, and numerous other factories are scattered over the district, while wheels, travelling boxes, hardwoods, and other raw materials are also worked in the vicinity. Ekaterinburg took its origin from the mining establishments founded by Peter the Great in 1721, and received its name in honour of his wife, Catherine I. Its development was greatly promoted in 1763 by the diversion of the Siberian highway from Verkhoturye to this place.

EKATERINODAR, a town of South Russia, chief town of the province of Kuban, on the right bank of the river Kuban, 85 m. E.N.E. of Novo-rossiysk, on the railway to Rostov-on-Don, and in 45° 2' N. and 38° 50' E. It is badly built, on a swampy site exposed to the inundations of the river; and its houses, with few exceptions, are slight structures of wood and plaster. Founded by Catherine II. in 1794 on the site of an old town called Tmutarakan, as a small port and Cossack settlement, its population grew from 6,500 in 1860 to 65,697 in 1897. It has various technical schools, an experimental farm, a military hospital, and a natural history museum. A considerable trade is carried on, especially in cereals.

EKATERINOSLAV, a government of South Russia, having the governments of Poltava and Kharkov on the N., the territory of the Don Cossacks on the E., the Sea of Azov and Taurida on the S., and Kherson on the W. Area, 24,478 sq. m. Its surface is undulating steppe, sloping gently south and north, with a few hills reaching 1,200 ft. in the N.E., where a slight swelling (the Don Hills) compels the Don to make a great curve eastwards. Another chain of hills, to which the eastward bend of the Dnieper is due, rises in the west. These hills have a crystalline core (granites, syenites and diorites), while the surface strata belong to the Carboniferous, Permian, Cretaceous and Tertiary formations. The government is rich in minerals, especially in coal—the mines lie in the middle of the Donets coalfield—iron ores, fireclay and rock-salt, and every year the mining output increases in quantity, especially of coal and iron. Granite, limestone, grindstone, slate, with graphite, manganese and mercury are found. The government is drained by the Dnieper, the Don and their tributaries (e.g. the Donets and Volchya) and by several affluents (e.g. the Kalmius) of the Sea of Azov. The soil is the fertile black earth, but the crops occasionally suffer from drought, the average annual rainfall being only 15 in. Forests are scarce. Pop. (1860) 1,368,530; (1897) 2,118,945, chiefly Little Russians, with Great Russians, Greeks (48,740), Germans (86,970), Italians and others. It has two cathedrals—St. Catherine's, instituted in 1728, and population. The estimated population in 1900 was 2,708,700. Wheat and other cereals are extensively grown; other noteworthy crops are potatoes, tobacco and grapes. Nearly 40,000 persons find occupation in factories, the most important being iron-works and agricultural machinery works, though there are also tobacco, glass, soap and candle factories, potteries, tanneries and breweries. In the districts of Mariupol the making of agricultural implements and machinery is carried on extensively as a domestic industry in the villages. Bees are kept in very considerable numbers. Fishing employs many persons in the Don and the Dnieper. Cereals are exported in large quantities via the Dnieper, the Sevastopol railway, and the port of Mariupol. The chief towns of the eight districts, with their populations in 1901, are: Tishinsk, 14,729; Khabovka, 17,618; Mariupol, 32,167; Novomoskovsk, 12,862; Pavlagrad (17,188), Sl'yvanovsky (3,212), and Verkhne-Dniepropetrovsk (11,607).

EKATERINOSLAV, a town of Russia, capital of the government of the same name, on the right bank of the Dnieper above the rapids, 653 m. by rail S.S. of Moscow, in 48° 21' N. and 35° 4' E., at an altitude of 210 ft. Pop. (1862) 36,681, without suburbs; (1900) 135,552. If the suburb of Novyikondak be included, the town extends for upwards of 4 m. along the river. The oldest part lies very low and is much exposed to floods. Contiguous to the towns on the N.W. is the royal village of Novyi-maidani or the New Factories. The bishop's palace, mining academy, archaeological museum and library are the principal public buildings. The house now occupied by the Nobles Club was formerly inhabited by the author and statesman Potemkin. The city is a small port with about 150 ships and 200 boats. It is a depot for ships, and is an important depot for timber floated down the Dnieper, and also for cereals. Its iron-works, flour-mills and agricultural machinery works give occupation to 5,000 persons. In fact since 1805 the city has become the centre of numerous Franco-Belgian industrial undertakings. In addition to the branches just mentioned, there are tobacco factories and breweries. Considerable trade is carried on in cattle, cereals, horses and wool, there being three annual fairs. On the site of the city there formerly stood the Polish castle of Koidak, built in 1635, and destroyed by the Cossacks. The existing city was founded by Potemkin in 1786, and in the following year Catherine II. laid the foundation-stone of the cathedral, though it was not actually built until 1830-1835. On the south side of it is a bronze statue of the empress, put up in 1846. Paul I. changed the name of the city to Novo-rossiysk, but the original name was restored in 1802.

EKHOF, KONRAD (1720-1778), German actor, was born in Hamburg on the 12th of August 1720. In 1739 he became a member of Johann Friedrich Schönenmann's (1704-1782) company in Lüneburg, and made his first appearance there on the 15th of January 1740 as Xiphares in Racine's Miïridate. From 1757 the Schönenmann company performed mainly in Hamburg and at Schwerin, where Duke Christian Louis II. of Mecklenburg-Schwerin made them comedians to the court. During this period Ekhof founded in Hamburg an operatic theatre, which, though short-lived, was of great importance in the German drama. It was the standard of German acting and the status of German actors. In 1757 Ekhof left Schönenmann to join Franz Schuch's company at Danzig; but he soon returned to Hamburg, where, in conjunction with two other actors, he succeeded Schönenmann in the direction of the company. He resigned this position, however, in favour of H. G. Koch, with whom he acted until 1764, when he joined K. E. Ackermann's company. In 1767 was founded the National Theatre at Hamburg, made famous by Lessing's Hamburgische Dramaturgie, and Ekhof was the leading member of the company. After the failure of the enterprise Ekhof was for a time in Weimar, and ultimately became co-director of the new court theatre at Gotha. This, the first permanently established theatre in Germany, was opened on the 2nd of October 1775. Ekhof's reputation was now at its height; Goethe called him the only German tragic actor; and in 1777 he acted with Duke Charles of Brunswick and Duke Charlotte of Weimar opposite Goethe at Weimar, dining afterwards with the poet at the ducal table. He died on the 16th of June 1788. His versatility may be judged from the fact that in the comedies of Goldoni and Molière he was no less successful than in the tragedies of Lessing and Shakespeare. He was regarded by his contemporaries as an unsurpassed exponent of naturalness on the stage; and in this respect he has been not unfairly compared with Garrick. His fame, however, was rapidly eclipsed by that of Friedrich U. L.
EKRON—ELAM

Schröder. His literary efforts were chiefly confined to translations from French authors.

See H. Uhde, biography of Ekhof in vol. iv. of Der neue Plutarch (1876), and J. Rüschner, K. Ekhofs Leben und Werke (1872); cf. H. Devrient, J. P. Schönemann und seine Schauspielergesellschaft (1895).

EKRON (better, as in the Septuagint and Josephus, ACCARON, Ἀκαρῶν), a royal city of the Philitines commonly identified with the modern Syrian village of Ἀκίρ, 5 m. from Ramleh, on the southern slope of a low ridge separating the plain of Philitis from Sharon. It lay inland and off the main line of traffic. Though included by the Israelites within the limits of the kingdom of Judah, and mentioned in Judges xix. and xxi., it inhabited a valley which may perhaps be the modern Māḥ-Sabadan, as well as the level district of Yamutbal or Yathur which separated Elam from Babylonia, and the smaller districts of Characene, Cabandene, Corbiana and Gabiene mentioned by classical authors, we come to the fourth principal tribe of Susiana, the Cissii (Aesch. Pers. 16; Strabo xv. 3, 2) or Cissaei (Strabo xii. 5, 6, xii. 17; Arr. Ind. 45; Polib. v. 54, &c.), the Kasii of the cuneiform inscriptions. So important were they, that the whole of Susiana was sometimes called Cissia after them, as by Herodotus (iii. 91, v. 49, &c.). In fact Susiana was only a late name for the country, dating from the time when Susa had been made a capital of the Persian Empire. In the Sumerian texts of Babylonia it was called Numma, "the Highlands," of which Elamtu or Elamu, "Elam," was the Semitic translation. Apart from Susa, the most important part of the country was Anzan (Anshan, contracted Assan), where the native population maintained itself unaffected by Semitic intrusion. The exact position of Anzan is still disputed, but it probably included originally the site of Susa and was distinguished from it only when Susa became the seat of a Semitic government. In the lexical tablets Anzan is given as the equivalent of Elamtu, and the native kings entitle themselves kings of "Anzan and Susa," as well as "princes of the Khapiri.

The principal mountains of Elam were on the north, called Charbanus and Cambalibus by Pliny (vi. 27, 31), and belonging to the Parachothas chain. There were numerous rivers flowing into either the Tigris or the Persian Gulf. The most important were the Ulai or Eulaeus (Kīrān) with its tributary the Pastorigis, the Choaspes (Kerkhah), the Coprates (river of Diā called Itiṭe in the inscriptions), the Hedyphon or Hedyphus (Terahd), and the Oroatīs (Kīrētum), besides the monumental Surappi and Uki, perhaps to be identified with the Hedyphon and Oroatīs, which fell into the sea in the marshy region at the mouth of the Tigris. Shushan or Susa, the capital now marked by the mounds of Shush, stood near the junction of the Choaspes and Eulaeus (see Susa); and Badaca, Maqaktu in the inscriptions, lay between the Shapur and the river of Diā. Among the other chief cities mentioned in the inscriptions may be named Naditu, Khaltemas, Din-sar, Bubuli, Bit-imbi, Khidas, and Nagitu on the sea-coast. Here, in fact, lay some of the oldest and wealthiest towns, the sites of which have, however, been removed inland by the silting up of the shore. J. de Morgan's excavations at Susa have thrown a flood of light on the early history of Elam and its relations to Babylon. The earliest settlement there goes back to neolithic times, but it was already a fortified city when Elam was conquered by Sargon of Akkad (3500 B.C.) and Susa became the seat of a Babylonian viceroy. From this time onward for many centuries it continued under Semitic suzerainty, its high-priests, also called "Chief Envoys of Elam, Sippara and Susa," bearing sometimes Semitic, sometimes native "Anzanite" names. One of the kings of the dynasty of Ur built at Susa. Before the rise of the First Dynasty of Babylon, however, Elam had recovered its independence, and in 2280 B.C. the Elamite king Kultur-Nabikhuhe made a raid in Babylonia and carried away thousands of prisoners. The monuments of many of his successors have been discovered by de Morgan and their inscriptions deciphered by v. Scheil. One of them was defeated by Ammi-zadq
of Babylon (c. 2100 B.C.); another would have been the Chedor-lasomer (Kutur-Lagamar) of Genesis xiv. One of the greatest builders among them was Untas-Gal (the pronunciation of the second element in the name is uncertain). About 1330 B.C. Khubaba-tita was captured by Kurru-gezlu III., the Kassite king of Babylon, but a later prince Kidin-Khurtrnas avenged his defeat, and Sutruk-Nakhkhunte (1230 B.C.) carried fire and sword through Babylonia, slew its king Zimara-sum-ididu and captured his palace. He was famous in the law of Khorsabad from Sippur, as well as a stela of Manishtusu from Akkuttum or Akkad. He also conquered the land of Assunnak and carried off from Padan a stela belonging to a refugee from Malatia. He was succeeded by his son who was followed by his throne by one of the great builders of Elam. In 750 B.C. Umibadda was king of Elam; Khubanigas was his successor in 742 B.C. In 730 B.C. the latter prince met the Assyrians against Sargon at Dur-ili in Vamutbal, and though Sargon claims a victory the result was that Babylon recovered its independence under Merodach-baladan and the Assyrian forces were driven north. From this time forward it was against Assyria instead of Babylon that Elam found itself compelled to exert its strength, and Elamite policy was directed towards fomenting revolt in Babylon and assisting the Babylonians in their struggle with Assyria. In 715 B.C. Khubanigas was defeated by his successor, Sutruk-Nakhkhunte. He failed to make head against the Assyrians; the frontier cities were taken by Sargon and Merodach-baladan was left to his fate. A few years later (704 B.C.) the combined forces of Elam and Babylon were overthrown at Kis, and in the following year the Kassites were reduced to subjection. The Elamite king was deposed and imprisoned in 700 B.C. by his brother Khallus, who six years later marched into Babylon, captured the son of Sennacherib, whom his father had placed there as king, and raised a nominee of his own, Surp-xurshu, to the throne. Khallus was murdered in 694 B.C., after seeing the maritime part of his dominions invaded by the Assyrians. His successor Kudur-Nakhkhunte invaded Babylonia; he was repulsed, however, by Sennacherib, 34 of his cities were destroyed, and he himself fled to Madaktu to Khidhalu. The result was a revolt in which he was killed after a reign of ten months. His brother Ummannemen at once collected allies and prepared for resistance to the Assyrians. But the terrible defeat at Khallit broke his power; he was attacked by paralysis shortly afterwards, and Khumba-Khadla II. followed him on the throne (688 B.C.). The new king endeavored to gain Assyrian favor by putting to death the son of Merodach-baladan, but was himself murdered by his brothers Urtaki and Teuman (681 B.C.), the first of whom seized the crown. On his death Teuman succeeded and almost immediately provoked a quarrel with Assur-bani-pal by demanding the surrender of nephews who had taken refuge at the Assyrian court. The Assyrians pursued the Elamite army to Susa, where a battle was fought on the banks of the Euacaeus, in which the Elamites were defeated, Teuman captured and slain, and Ummannigas, the son of Urtaki, made king, his younger brother Tammaritu being given the district of Khidhalu. Ummannigas afterwards assisted in the revolt of Babylonia under Samsu-sum-yukin, but his nephew, a second Tammaritu, raised a rebellion against him, defeated him in battle, cut off his head and seized the crown. Tammaritu marched to Babylonia; while there, his officer Inda-bigas made himself master of Susa and drove Tammaritu to the coast whence he fled to Assur-bani-pal. Inda-bigas was himself overthrown and slain by a new pretender, Khumba-Khadla III., who was opposed, however, by three other rivals, two of whom maintained themselves in the mountains until the Assyrian conquest of the country, when Tammaritu was first restored and then imprisoned, Elam being utterly dired and was followed by his nephew, Sutruk-Nakhkhunte, to a fresh Assyrian invasion; the Elamite king fled from Madaktu to Dur-undasi; Susa and other cities were taken, and the Elamite army almost exterminated on the banks of the Iltiu. The whole country was reduced to a desert, Susa was plundered and razed to the ground, the royal sepulchres were desecrated, and the images of the gods and of 32 kings "in silver, gold, bronze and alabaster," were carried away. All this must have happened about 640 B.C. After the fall of the Assyrian empire Elam was occupied by the Persian Teispes, the forfather of Cyrus, who, accordingly, like his immediate successors, is called in the inscriptions "king of Anzan." Susa once more became a capital, and on the establishment of the Persian empire remained one of the three seats of government, its language, the Neo-Babylonian, making with the Persic a kind of Semitic of Babylon as an official tongue. In the reign of Darius, however, the Susians attempted to revolt, first under Assina or Atrina, the son of Umibadda, and later under Martinia, the son of Issinaskia, who called himself Immanes; but they gradually became completely Aryanized, and their agglutinative dialects were supplanted by the Aryan Persian from the south-east.

Elam, "the land of the cedar-forest," with its enchanted trees, figured largely in Babylonian mythology, and one of the adventures of the hero Gilgamesh was the destruction of the tyrant Khumbaba who dwelt in the midst of it. A list of the Elamite deities is given by Assur-bani-pal; at the head of them was In-Susinak, "the lord of the Susians," —a title which went back to the age of Babylonian suzerainty,—whose image and oracle were hidden from the eyes of the profane. Nakhkhunte, according to Scheil, was the Sun-goddess, and Lagamar, whose images were found in the ruins, was identified with the Babylonian "God of the breezy wind," and was worshiped as a god of the air. It is probable that the first name of the goddess is the same as that of the goddess of Semitic Babylonia.

See W. K. Loftus, Chaldaeans and Susians (1877); A. Billerbeck, Susa (1893); J. de Morgan, Memoires de la Division de Persia (9 vols., 1899—1906).

ELAND (= elk), the Dutch name for the largest of the South African antelopes (Taurotragus oryx), a species native akin to the kudu, but with horns present in both sexes, and their spiral much closer, being in fact screw-like instead of cork-screw-like. The male is also a large animal, while old bulls have a thick forehead. In the typical southern form the body-colour is wholly pale fawn, but north of the Orange river the body is marked by narrow vertical white lines, this race being known as T. oryx livingstonii. In Sonegambia the genus is represented by T. derbianus, a much larger animal, with a dark neck; while in the Bahr-el-Ghazal district there is a gigantic local race of this species (T. derbianus gigas).

ELASTICITY. 1. Elasticity is the property of recovery of an original size or shape. A body of which the size, or shape, or both size and shape, have been altered by the application of forces may, and generally does, tend to return to its previous size and shape when the forces cease to act. Bodies which exhibit this tendency are said to be elastic (from Greek, dhaleusin, to drive). All bodies are more or less elastic as regards size; and all solid bodies are more or less elastic as regards shape. The ideal gas contained in a vessel, which is closed by a piston, can be compressed by additional pressure applied to the piston; but, when the additional pressure is removed, the gas expands and drives the piston outwards. For a second example: a steel bar hanging vertically, and loaded with one ton for each square inch of its sectional area, will have its length increased by about seven one-hundred-thousandths of itself, and its sectional area diminished by about half as much; and it will spring back to its original length and sectional area when the load is gradually removed. Such changes of size and shape in bodies subjected to forces, and the recovery of the original size and shape when the forces cease to act, become conspicuous when the bodies have the forms of thin wires or planks; and these properties of bodies in such forms are utilized in the construction of spring balances, carriage springs, buffers and so on.

It is a familiar fact that the hair-spring of a watch can be coiled and uncoiled millions of times a year for several years without losing its elasticity; yet the same spring can have its shape permanently altered by forces which are much greater than those to which it is subjected in the motion of the watch. The incompleteness of the recovery from the effects of great forces is as important a fact as the practical completeness of the recovery from the effects of comparatively small forces.
ELASTICITY

The fact is referred to in the distinction between "perfect" and "imperfect" elasticity; and the limitation which must be imposed upon the forces in order that the elasticity may be perfect leads to the investigation of "limits of elasticity" (see §§ 31, 32 below). Steel pianoforte wire is perfectly elastic within rather wide limits, glass within rather narrow limits; building stone, cement and cast iron appear not to be perfectly elastic within any limits, however narrow. When the limits of elasticity are not exceeded no injury is done to a material or structure by the action of the forces. The strength or weakness of a material, and the safety or insecurity of a structure, are thus closely related to the elasticity of the material and to the change of size or shape of the structure when subjected to forces. The "science of elasticity" is occupied with the more abstract side of this relation, viz. with the effects that are produced in a body of definite size, shape and composition by definite forces; the "science of the strength of materials" is occupied with the more concrete side, viz. with the application of the results obtained in the science of elasticity to practical questions of strength and safety (see STRENGTH OF MATERIALS).

2. Stress.—Every body that we know anything about is always under the action of forces. Every body upon which we can experiment is subject to the force of gravity, and must, for the purpose of experiment, be supported by other forces. Such forces are usually applied as pressure of the upper portion of the surface of the body; and such pressure is exerted by another body in contact with the first. The supported body exerts an equal and opposite pressure upon the supporting body across the portion of surface which is common to the two. The same thing is true of two portions of the same body. If, for example, we consider the two portions into which a body is divided by a (geometrical) horizontal plane, we conclude that the lower portion supports the upper portion by pressure across the plane, and the upper portion presses downwards upon the lower portion with an equal pressure. The pressure is still exerted when the plane is not horizontal, and its direction may be obliquely inclined to, or tangential to, the plane. A more precise meaning is given to "pressure" below. It is important to distinguish between the two classes of forces: forces such as the force of gravity, which act all through a body, and forces such as pressure applied over a surface. The former are named "body forces" or "volume forces," and the latter "surface tractions." The action between two portions of a body separated by a geometrical surface is of the nature of surface traction. Body forces are ultimately, when the volumes upon which they act are small enough, proportional to the volumes; surface tractions, on the other hand, are ultimately, when the surfaces across which they act are small enough, proportional to these surfaces. Surface tractions are always exerted by one body upon another, across a surface of contact; and a surface traction is always to be regarded as one aspect of a "stress," that is to say a pair of equal and opposite forces; for an equal traction is always exerted by the second body, or part, upon the first across the surface.

The proper method of estimating and specifying stress is a matter of importance, and its character is necessarily matrix to the magnitude of the tractions that compose a stress are estimated as so much force (in dynes or tons) per unit of area (per sq. cm. or per sq. in.). The traction across an assigned plane at an assigned point is measured by the mathematical limit of the fraction F/S, where F denotes the numerical measure of the force exerted across a small portion of the plane containing the point, and S denotes the numerical measure of the area of this portion, and the limit is taken by diminishing S indefinitely. The traction may act as "tension," as it does in the case of a horizontal section of a bar supported at its upper end and hanging vertically, or as "pressure," as it does in the case of a horizontal section of a block resting on a horizontal plane, or again it may act obliquely or even tangentially to the separating plane. Normal tractions are reckoned as positive when they are tensions, negative when they are pressures. Tangential tractions are often called "shears" (see § 7 below). Oblique tractions can always be resolved, by the vector law, into normal and tangential tractions. In a fluid at rest the traction across any plane at any point is normal to the plane, and acts as pressure. For the complete specification of the "state of stress" at any point of a body, we should require to know the normal and tangential components of the traction across every plane drawn through the point. Fortunately this requirement can be very much simplified (see §§ 6, 7 below).

4. In general let s denote the direction of the normal drawn in a specified sense to a plane drawn through a point O of a body; and let T denote the traction exerted across the plane, at the point O, in the direction of the traction towards which s is drawn on the remaining portion. Then T is a vector quantity having magnitude (estimated as above by the limit of a fraction of the form F/S) and a definite direction. It can be specified completely by its components Xs, Ys, Zs; and a similar notation is used when the direction of s is that of y or z, the suffix x being replaced by y or z.

5. Every body about which we know anything is always in a state of stress, that is to say there are always internal forces acting between the parts of the body, and these forces are exerted as surface tractions across geometrical surfaces drawn in the body. The body, and each part of the body, moves under the action of all the forces (body forces and surface tractions) which are exerted upon it; or remains at rest if these forces are in equilibrium. This statement is expressed analytically by means of certain equations—the "equations of motion" or "equations of equilibrium" of the body.

Let \( \rho \) denote the density of the body at any point, \( X, Y, Z \) the components parallel to the axes of \( x, y, z \) of the body forces, estimated so much force per unit of mass; further let \( f_x, f_y, f_z \) denote the components, parallel to the same axes, of the acceleration of the particle which is momentarily at the point \( (x, y, z) \). The equations of motion express the result that the rates of change of the momentum, and of the moment of momentum, of any particle, are those due to the action of all the forces exerted upon the particle by other bodies, or by other portions of the same body. For the changes of momentum of the type

\[
\int f_x dx \frac{dx}{dy} + \int f_y dx \frac{dy}{dz} + \int f_z dx \frac{dz}{dy},
\]

in which the volume integrations are taken through the volume of the portion of the body, the surface integration is taken over the surface, and the notation \( \int \mathbf{s} \cdot \mathbf{dA} = \int f_x dx \frac{dx}{dy} + \int f_y dx \frac{dy}{dz} + \int f_z dx \frac{dz}{dy} \)

is used, the equations of motion are obtained by replacing the right-hand members of these equations by zero.

6. These equations can be used to obtain relations between the values of \( \rho \), \( X, Y, Z \) for different directions. When the body is applied to a very small volume, it appears that the terms expressed by surface integrals would, unless they tend to zero limits in a higher order than the areas of surfaces, be very great compared with the terms expressed by volume integrals. We conclude that the surface tractions on the portion of the body which is bounded by any very small closed surface, are ultimately, in equilibrum. When this result is interpreted for a small portion in the shape of a tetrahedron, having three of its faces at right angles to the coordinate axes, it leads to three equations of the type

\[
X = X_0 \cos(s) + X_2 \cos(y),
\]

where \( s \) is the direction of the normal (drawn outwards) to the remaining face of the tetrahedron, and \( X_0, X_2, \ldots \) denote the angles which this normal makes with the axes. Hence \( X_0, \ldots \) for any direction \( s \) are expressed in terms of \( X_0, \ldots \). When the above is interpreted for a very small portion in the shape of a cube, having its edges parallel to the coordinate axes, it leads to the equations

\[
Y = Y_0, \quad Z = Z_0, \quad X = X_0 - Y_0.
\]

When we substitute in the general equations the particular results which are thus obtained, we find that the equations of motion take such forms as

\[
\rho X + \frac{\partial f}{\partial x} + X_0 \frac{\partial f}{\partial y} + \frac{\partial f}{\partial z} = f_x,
\]

and the equations of moments are satisfied identically. The equations of equilibrium are obtained by replacing the right-hand members by zero.
7. A state of stress in which the traction across any plane of a set of parallel planes is normal to the plane, and that across any perpendicular plane vanishes, is described as a state of "simple tension" ("simple pressure" if the traction is negative). A state of stress in which the traction across any plane parallel to the plane, and the traction is the same for all planes passing through any point, is described as a state of "uniform tension" ("uniform pressure" if the traction is negative). Sometimes the phrases "isotropic tension" and "hydrostatic pressure" are used instead of "uniform" tension or pressure. The distinction between the two states, simple tension and uniform tension, is illustrated in Fig. 1.

A state of stress in which there is purely tangential traction on a plane, and no normal traction on any perpendicular plane, is described as a state of "shearing stress." The result (2) of § 6 shows that tangential tractions occur in pairs. If, at any point, there is tangential traction, in any direction, on a plane parallel to this direction, and if we draw through the point a plane at right angles to the direction of this traction, and therefore containing the normal to the first plane, then there is equal tangential traction on this second plane in the direction of the normal to the first plane. The result is illustrated in Fig. 2, where a rectangular block is subjected on two opposite faces to opposing tangential tractions, and is held in equilibrium by equal tangential tractions applied to two other faces.

Through any point there always pass three planes, at right angles to each other, across which there is no tangential traction. These planes are called the "principal planes of stress," and the (normal) tractions across them are the "principal stresses." Lines, usually curved, which have at every point the direction of a principal stress at the point, are called "lines of stress."

8. It appears that the stress at any point of a body is completely specified by six quantities, which can be taken to be the \(X_x, Y_y, Z_z\) and \(X_x, Y_y, Z_z\) of § 6. The first three are tensions (pressures if they are negative) across three planes parallel to fixed rectangular directions, and the remaining three are tangential tractions across the same three planes. These six quantities are called the "components of stress." It appears also that the components of stress are connected with each other, and with the body forces and accelerations, by the three partial differential equations of the type (3) of § 6. These equations are available for the purpose of determining the state of stress which exists in a body of definite form subjected to definite forces, but they are not sufficient for the purpose (see § 36 below). In order to effect the determination it is necessary to have information concerning the constitution of the body, and to introduce subsidiary relations founded upon this information.

9. The definite mathematical relations which have been found to connect the components of stress with each other, and with other quantities, result necessarily from the formation of a clear conception of the nature of stress. They do not admit of experimental verification, because the stress within a body does not admit of direct measurement. Results which are deduced by the aid of these relations can be compared with experimental results. If any discrepancy was observed it would not be interpreted as requiring a modification of the concept of stress, but as affecting some one or other of the subsidiary relations which must be introduced for the purpose of obtaining the theoretical result.

10. Strain.—For the specification of the changes of size and shape which are produced in a body by stress forces begin by defining the "average extension" of any linear element or "filament" of the body. Let \(l_0\) be the length of the filament before the forces are applied, \(l\) its length when the body is subjected to the forces. The average extension of the filament is measured by the fraction \((l-l_0)/l_0\). If this fraction is negative there is "contraction." The "extension at a point" of a body in any assigned direction is the mathematical limit of this fraction when one end of the filament is at the point, the filament has the assigned direction, and its length is diminished indefinitely. It is clear that all the changes of size and shape of the body are known when the extension at every point in every direction is known.

The relations between the extensions in different directions around the same point are most simply expressed by introducing the same in the directions of the co-ordinate axes and the angles between filaments of the body which are initially parallel to these axes. Let \(e_{xx}, e_{yy}, e_{zz}\) denote the extensions parallel to the axes of the body, \(e_{xy}, e_{yz}, e_{zx}\) denote the co-angles of the angles between the pairs of filaments which are initially parallel to the axes of \(x, y, \) and \(z\) and \(x, z\) and \(y, z\). Also let \(\theta\) denote the extension in the direction of a line the direction cosines of which are \(m, n, \) and \(p.\) Then, if the changes of size and shape are slight, we have the relation

\[
e = e_{xx}^{mp} + e_{yy}^{np} + e_{zz}^{mq} - e_{xy}^{mp} + e_{yz}^{np} + e_{zx}^{mq}.
\]

The body which undergoes the change of size or shape is said to be "strained," and the "strain" is determined when the quantities \(e_{xx}, e_{yy}, \) and \(e_{zz}\) and \(e_{xy}, e_{yz}, e_{zx}\) defined above are known at every point of it. These quantities are called "components of strain." The three of the type \(e_{xx}\) are extensions, and the three of the type \(e_{xy}\) are called "shearing strains" (see § 12 below).

11. All the changes of relative position of particles of the body are known when the strain is known, and conversely the strain can be determined when the changes of relative position are given. These changes can be expressed most simply by the introduction of a vector quantity to represent the "displacement" of any particle.

When the body is deformed by the action of any forces its particles pass from the positions which they occupied before the action of the forces into new positions. If \(x, y, z\) are the co-ordinates of the position of a particle in the first state, its co-ordinates in the second state may be denoted by \(x, y, z\) and \(\delta x, \delta y, \delta z\). The quantities \(\delta x, \delta y, \delta z\) are the "components of displacement." When these quantities are small, the strain is connected with them by the equations

\[
\begin{align*}
\delta x &= \frac{\partial u}{\partial x} \delta x + \frac{\partial u}{\partial y} \delta y + \frac{\partial u}{\partial z} \delta z, \\
\delta y &= \frac{\partial v}{\partial x} \delta x + \frac{\partial v}{\partial y} \delta y + \frac{\partial v}{\partial z} \delta z, \\
\delta z &= \frac{\partial w}{\partial x} \delta x + \frac{\partial w}{\partial y} \delta y + \frac{\partial w}{\partial z} \delta z.
\end{align*}
\]

12. These equations enable us to determine more exactly the nature of the "shearing strains" such as \(e_{xy}\). Let \(s, t, u\), for example, be the form of the surface, \(d, e,\) and \(f, g,\) vanish. Then \(e_{xy} = s,\) and the remaining components of strain vanish.

The nature of the strain (called "simple shear") is simply appreciated by imagining the body to consist of a series of thin sheets, like the leaves of a book, which lie one over another and are all parallel to a plane (that of \(x, z\)); and the displacement is seen to consist in the shifting of each sheet relative to the sheet below in a direction (that of \(z\)) which is the same for all the sheets. The displacement of any sheet is proportional to its distance \(y\) from a particular sheet, which remains undisplaced.

The shearing strain has the effect of distorting the shape of any portion of the body without altering its volume. This is shown in Fig. 3, where a square ABCD is distorted by simple shear (each point moving parallel to the line marked zz into a rhombus A'B'C'D', as if by an extension of the diagonal BD and a contraction of the diagonal AC, which extension and contraction are adjusted so as to leave the area unaltered. In the general case, where \(w\) is not of the form \(xy\) and \(z\) and \(w\) do not vanish, the shearing strains such as \(e_{xy}\) result from the decomposition of pairs of simple shears of the type which has just been explained.
13. Besides enabling us to express the extension in any direction and the changes of relative direction of any filaments of the body, the components of strain also express the changes of size of volumes and areas. In particular, the "cubical dilatation," that is to say, the increase of volume per unit of volume, is expressed by the quantity $\varepsilon_a + \varepsilon_b + \varepsilon_c$ of $\partial u \over \partial x + \partial v \over \partial y + \partial w \over \partial z$. When this quantity is negative there is "compression."

![Figure 3](image)

must be a displacement which can be associated with it in accordance with the equations (1) of § 11.

We may eliminate $u, v, w$ from these equations. When this is done we find that the quantities $\varepsilon_a, \varepsilon_b, \varepsilon_c$ are connected by the two sets of equations

\[ \begin{align*}
\frac{\partial^2 \varepsilon_a}{\partial x^2} + \frac{\partial^2 \varepsilon_a}{\partial y^2} + \frac{\partial^2 \varepsilon_a}{\partial z^2} &= \frac{\partial^2 \varepsilon_b}{\partial x^2} + \frac{\partial^2 \varepsilon_b}{\partial y^2} + \frac{\partial^2 \varepsilon_b}{\partial z^2} \quad (1) \\
\frac{\partial^2 \varepsilon_b}{\partial x^2} + \frac{\partial^2 \varepsilon_b}{\partial y^2} + \frac{\partial^2 \varepsilon_b}{\partial z^2} &= \frac{\partial^2 \varepsilon_c}{\partial x^2} + \frac{\partial^2 \varepsilon_c}{\partial y^2} + \frac{\partial^2 \varepsilon_c}{\partial z^2} 
\end{align*} \]

and

\[ \begin{align*}
\frac{\partial^2 \varepsilon_a}{\partial y \partial z} &= \frac{\partial^2 \varepsilon_b}{\partial x \partial z} \\
\frac{\partial^2 \varepsilon_b}{\partial x \partial y} &= \frac{\partial^2 \varepsilon_c}{\partial x \partial y} \\
\frac{\partial^2 \varepsilon_c}{\partial y \partial x} &= \frac{\partial^2 \varepsilon_a}{\partial y \partial x} 
\end{align*} \]

These equations are known as the conditions of compatibility of strain-components. The components of strain which specify any possible strain satisfy them. Quantities arrived at in any way, and intended to be components of strain, if they fail to satisfy these equations, are not the components of any possible strain; and the theory or speculation by which they are reached must be modified or abandoned.

When the components of strain have been found in accordance with these and other necessary equations, the displacement is to be found by solving the equations (1) of § 11, considered as differential equations to determine $u, v, w$. The most general possible solution will differ from any other solution by terms which contain arbitrary constants, and these terms represent a possible displacement. This "complementary displacement" involves no strain, and would be a possible displacement of an ideal perfectly rigid body.

14. It is important to distinguish between two types of strain: the "rotational" type and the "irrotational" type. The distinction is illustrated in fig. 3, where the figure $A'B'C'D'$ is obtained from the figure $ABCD$ by contraction parallel to $AC$ and extension parallel to $BD$, and the figure $A'B'C'D'$ can be obtained from $ABCD$ by the same contraction and extension followed by a rotation through the angle $A'OA$. In strains of the irrotational type there are at any point three filaments at right angles to each other, which are such that the particles which lie in them before strain continue to lie in them after strain. A small spherical element of the body with its centre at the point becomes a small ellipsoid with its axes in the directions of these three filaments. In the case illustrated in the figure, the lines of the filaments in question, when the figure $ABCD$ is strained into the figure $A'B'C'D'$, are $OA$, $OB$, and a line through $O$ at right angles to their plane. In strains of the rotational type, on the other hand, the single existing set of three filaments (issuing from a point) which cut each other at right angles both before and after strain do not retain their directions after strain, though one of them may do so in certain cases. In the figure, the lines of the filaments in question, when the figure $ABCD$ is strained into $A'B'C'D'$, are $OA$, $OB$, and a line at right angles to their plane before strain, and after strain they are $OA'$, $OB'$, and the same third line. A rotational strain can always be analyzed into an irrotational strain (or "pure" strain) followed by a rotation.

Analytically, a strain is irrotational if the three quantities

\[ \frac{\partial \varepsilon_a}{\partial x} - \frac{\partial \varepsilon_b}{\partial y} + \frac{\partial \varepsilon_c}{\partial z} = 0 \quad (2) \]

vanish, rotational if any one of them is different from zero. The values of these three quantities are the components of a vector quantity called the "rotation."

15. Whether the strain is rotational or not, there is always one set of three linear elements issuing from any point which cut each other at right angles both before and after strain. If these directions are chosen as axes of $x, y, z$, the shearing strains $\varepsilon_a, \varepsilon_b, \varepsilon_c$ vanish at this point. These directions are called the "principal axes of strain," and the extensions in the directions of these axes the "principal extensions."

16. It is very important to observe that the relations between components of strain and components of displacement imply relations between the components of strain themselves. If by any process of reasoning we arrive at the conclusion that the state of strain in a body is such and such a state, we have a test of the possibility or impossibility of our conclusion. The test is that, if the state of strain is a possible one, then there

17. The relations which connect the strains with each other and with the displacement are geometrical relations resulting from the definitions of the quantities and not requiring any experimental verification. They do not admit of such verification, because the strain within a body cannot be measured. The quantities (belonging to the same category) which can be measured are displacements of points on the surface of a body. For example, on the surface of a bar subjected to tension we may make two fine transverse scratches, and measure the distance between them before and after the bar is stretched. For such measurements very refined instruments are required. Instruments for this purpose are called barabara "extensometers," and many different kinds have been devised. From measurements of displacement by an extensometer we may deduce the average extension of a filament of the bar terminated by the two scratches. In general, when we attempt to measure a strain, we really measure some displacements, and deduce the values, not of the strain at a point, but of the average extensions of some particular linear filaments of a body containing the point; and these filaments are, from the nature of the case, nearly always superficial filaments.

18. In the case of transparent materials such as glass there is available a method of studying experimentally the state of strain within a body. This method is founded upon the result that a piece of glass when strained becomes doubly refracting, with its optical principal axes at any point in the directions of the principal axes of strain (§ 15) at the point. When the piece has two parallel plane faces, and two of the principal axes of strain at any point are parallel to these faces, polarized light transmitted through the piece in a direction normal to the faces can be used to determine the directions of the principal axes of the strain at any point. If the directions of these axes are known theoretically the comparison of the experimental and theoretical results yields a test of the theory.

19. Relations between Stresses and Strains.—The problem of the extension of a bar subjected to tension is the one which has been most studied experimentally, and as a result of this study it is found that for most materials, including all metals except cast metals, the measurable extension is proportional
to the applied tension, provided that this tension is not too great. In interpreting this result it is assumed that the tension is uniform over the cross-section of the bar, and that the extension of longitudinal filaments is uniform throughout the bar; and then the result takes the form of a law of proportionality connecting stress and strain: The tension is proportional to the extension. Similar results are found for the same materials when other methods of experimenting are adopted, for example, when a bar is supported at the ends and bent by an attached load and the deflection is measured, or when a bar is twisted by an axial couple, and the relative angular displacement of two sections is measured. We have thus very numerous experimental verifications of the famous law first enunciated by Robert Hooke in 1678 in the words "'Ul Tensio sic vis''; that is, "the Power of any spring is in the same proportion as the Tension (stretcing) thereof." The most general statement of Hooke's Law in modern language would be: Each of the six components of stress at any point of a body is a linear function of the six components of strain at the point. It is evident from what has been said above as to the nature of the measurement of stresses and strains that this law in all its generality does not admit of complete experimental verification, and that the evidence for it consists largely in the agreement of the results which are deduced from it in a theoretical fashion with the results of experiments. Of such results one of a general character may be noted here. If the law is assumed to be true, and the equations of motion of the body (§ 3) are transformed by means of it into differential equations for determining the components of displacement, these differential equations admit of solutions which represent periodic vibrations, displacements (see § 85 below). The fact that solid bodies can be thrown into states of isochoronic vibration has been emphasized by G. G. Stokes as a peremptory proof of the truth of Hooke's Law.

20. According to the statement of the generalized Hooke's Law, the strain-components vanish when the strain-components vanish. The strain-components contemplated in experiments upon which the law is founded are measured from a zero of reckoning which corresponds to the state of the body subjected to experiment before the experiment is made, and the stress-components referred to in the statement of the law are those which are called into action by the forces applied to the body in the course of the experiment. No account is taken of the stresses which must already exist in the body owing to the force of gravity and the forces by which the body is supported. When it is desired to take account of this stress it is usual to suppose that the strains which would be present in the body if it could be freed from the action of gravity and from the pressures of supports are so small that the strains produced by the forces which are applied in the course of the experiment can be compounded with them by simple superposition. This supposition comes to the same thing as measuring the strain in the body, not from the state in which it was before the experiment, but from an ideal state (the "unstressed" state) in which it would be entirely free from internal stress, and allowing for the strain which would be produced by gravity and the supporting forces if these forces were applied to the body when free from stress. In most practical cases the initial strain to be allowed for is unimportant (see § 85 below).

21. Hooke's law of proportionality of stress and strain leads to the introduction of important physical constants: the modulus of elasticity of a body. Let a bar of uniform section (of area a) be stretched with tension T, which is distributed uniformly over the section, so that the stretching force is Tw, and let the bar be unsupported at the sides. The bar will undergo a longitudinal extension of magnitude T/E, where E is a constant quantity depending upon the material. This constant is called Young's modulus after Thomas Young, who introduced it into the science in 1807. The quantity E is of the same nature as a traction, that is to say, it is measured as a force estimated per unit of area. For steel it is about 2 x 10^11 dynes per square centimetre, or about 13,000 tons per sq. in.

22. The longitudinal extension of the bar under tension is not the only strain in the bar. It is accompanied by a lateral contraction by which all the transverse filaments of the bar are shortened. The amount of this contraction is $\sigma / E$, where $\sigma$ is a certain number called Poisson's ratio, because its importance was first noted by S. D. Poisson in 1828. Poisson arrived at the existence of this contraction, and the corresponding number $\nu$, from theoretical considerations, and his theory led him to assign to $\nu$ the value $\frac{1}{2}$. Many experiments have been made with the view of determining $\nu$, with the result that it has been found to be different for different materials, although for very many it does not differ much from $\frac{1}{2}$. For steel the best value (Amagat's) is $\nu = 0.28$. Poisson's theory admits of being modified so as to agree with the results of experiment.

23. The behaviour of an elastic solid body, strained within the limits of its elasticity, is entirely determined by the constants $E$ and $\nu$ if the body is isotropic, that is to say, if it has the same quality in all directions around any point. Nevertheless it is convenient to introduce other constants which are related to the action of particular sorts of forces. The most important of these are the "modulus of compression" (or "bulk modulus") and the "rigidity" (or "modulus of shear"). To define the modulus of compression, we suppose that a solid body of any form is subjected to uniform hydrostatic pressure of amount $p$. The state of stress within it will be one of uniform pressure, the same at all points, and the same in all directions round any point. There will be compression; the same at all points, and proportional to the amount of compression can be expressed as $p/k$. The quantity $k$ is the modulus of compression. In this case the linear contraction in any direction is $p/k$; but in general the linear extension (or contraction) is not one-third of the cubical dilatation (or compression).

24. To define the rigidity, we suppose that a solid body is subjected to forces in such a way that there is shearing stress within it. For example, a cubical block may be subjected to opposing tractions on one of its faces acting in directions parallel to an edge of the cube and to both the faces. Let $S$ be the amount of the traction; and let it be uniformly distributed over the faces. As we have seen (§ 7), equal tractions must act upon two other faces in suitable directions in order to maintain equilibrium (see fig. 2 of § 7). The two directions involved may be chosen as axes of $x$, $y$ as in that figure. Then the state of stress will be one in which the stress-component denoted by $X$, is equal to $S$, and the remaining stress-components vanish; and the strain produced in the body is shearing strain of the type denoted by $\varepsilon_{xy}$. The amount of the shearing strain is $S/\mu$, and the quantity $\mu$ is the "rigidity."

25. The modulus of compression and the rigidity are quantities of the same kind as Young's modulus. The modulus of compression of steel is about 2 x 10^{11} dynes per square centimetre, the rigidity is about 8 x 10^{10} dynes per square centimetre. It must be understood that the values for different specimens of nominally the same material may differ considerably.

The modulus of compression $k$ and the rigidity $\mu$ of an isotropic material are connected with the Young's modulus $E$ and Poisson's ratio $\nu$ of the material by the equations

$$k = E/(1 + \nu)(1 - 2 \nu), \quad \mu = E/(2(1 + \nu))$$

26. Whatever the forces acting upon an isotropic solid body may be, provided that the body is strained within its limits of elasticity, the strain-components are expressed in terms of the stress-components by the equations

$$\varepsilon_{xx} = (X_x - \nu \varepsilon_{yy} - \nu \varepsilon_{zz})/E, \quad \varepsilon_{yy} = Y_y/\nu, \quad \varepsilon_{zz} = (Y_z - \nu \varepsilon_{xx})/E, \quad \varepsilon_{xy} = (Z_y - \nu \varepsilon_{xx} - \nu \varepsilon_{yy})/E, \quad \varepsilon_{xz} = (Z_x - \nu \varepsilon_{xx} - \nu \varepsilon_{zz})/E, \quad \varepsilon_{yz} = (Z_y - \nu \varepsilon_{yy} - \nu \varepsilon_{zz})/E.$$

If we introduce a quantity $\lambda$, of the same nature as $E$ or $\mu$, by the equation

$$\lambda = E/(1 + \nu)(1 - 2 \nu),$$

we may express the stress-components in terms of the strain-components by the equations

$$X_x = \lambda(\varepsilon_{xx} + \nu \varepsilon_{yy} + \nu \varepsilon_{zz} + 2 \mu \varepsilon_{xy}), \quad Y_y = \lambda(\varepsilon_{yy} + \nu \varepsilon_{xx} + \nu \varepsilon_{zz} + 2 \mu \varepsilon_{yz}), \quad Z_z = \lambda(\varepsilon_{zz} + \nu \varepsilon_{xx} + \nu \varepsilon_{yy} + 2 \mu \varepsilon_{xz})$$

and then the behaviour of the body under the action of any forces.
ELASTICITY

depends upon the two constants $A$ and $\mu$. These two constants were introduced by G. Lamé in his treatise of 1832. The importance of the quantity $\mu$ had been previously emphasized by L. J. Vicat and G. G. Stokes.

The potential energy per unit of volume (often called the "resilience") stored up in the body by the strain is equal to

$$\sigma(1+2\mu)(e_{xx}+e_{yy}+e_{zz})+\mu(e_{xx}+e_{yy}+e_{zz}^2-4e_{xx}^2-4e_{yy}^2-4e_{zz}^2),$$
or the equivalent expression

$$\sigma[Y_{xx}+2Y_{yy}+2Y_{zz}-2e_{xx}(Y_{xx}+Z_{xx}+X_{xx}+Y_{yy})+2(1+\mu)(Y_{xx}^2+Z_{xx}^2+X_{xx}^2)]/E.$$

The former of these expressions is called the "strain-energy-functional." 28. The Young's modulus $E$ of a material is often determined experimentally by the direct method of the extensometer (§ 17), but more frequently it is determined indirectly by means of a result obtained in the theory of the flexure of a bar (see §§ 47, 53 below). The rigidity $\mu$ is usually determined indirectly by means of results obtained in the theory of the torsion of a bar (see §§ 41, 42 below). The modulus of compression $k$ may be determined directly by means of the piezometer, as was done by E. H. Amagat, or it may be determined indirectly by means of a result obtained in the theory of a tube under pressure, as was done by A. Mallock (see § 78 below). The value of Poisson's ratio $\sigma$ is generally inferred from the relation connecting it with $E$ and $\mu$ or with $E$ and $k$, but it may also be determined indirectly by means of a result obtained in the theory of the flexure of a bar (§ 47 below), as was done by M. A. Cornu and A. H. P. Mallock, or indirectly by a modification of the extensometer method, as has been done recently by J. Morrow.

29. The elasticity of a fluid is always expressed by means of a single quantity of the same kind as the modulus of compression of a solid body. To any increment of pressure, which is not too great, there corresponds a proportional cubical compression, and the amount of this compression for an increment $dp$ of pressure can be expressed as $dp/h$. The quantity that is usually tabulated is the reciprocal of $h$, and it is called the coefficient of compressibility. It is the amount of compression per unit increase of pressure. As a physical quantity it is of the same dimensions as the reciprocal of a pressure (or of a force per unit of area). The pressures concerned are usually measured in atmospheres (1 atmosphere $= 1.014 \times 10^6$ dynes per sq. cm.). For water the coefficient of compressibility, or the compression per atmosphere, is about $4.5 \times 10^{-5}$. This gives for $h$ the value $2.22 \times 10^6$ dynes per sq. cm. The Young's modulus and the rigidity of a fluid are always zero.

30. The relations between stress and strain in a material which is not isotropic are much more complicated. In such a material the Young's modulus depends upon the direction of the tension, and its variations about a point are expressed by means of a surface of the fourth degree. The Poisson's ratio depends upon the direction of the contracted lateral filament as well as upon that of the longitudinal extended ones. The rigidity depends upon both the directions involved in the specification of the shearing stress. In general there is no simple relation between the Young's moduluses and Poisson's ratios and rigidities for assigned directions and the modulus of compression. Many materials in common use, all fibrous woods for example, are actually anisotropic (that is to say, are not isotropic), but the materials which are anisotropic in the most regular fashion are the natural crystals. The behavior of crystals has been studied exhaustively by many physicists, and in particular by W. Voigt. The strain-energy-function is a homogeneous quadratic function of the six strain-components, and this function may have as many as 21 independent coefficients, taking the place in the general case of the 2 coefficients $\lambda$, $\mu$ which occur when the material is isotropic—a result first obtained by George Green in 1837. The best experimental determinations of the coefficients have been made indirectly by Voigt by means of results obtained in the theories of the torsion and flexure of anisotropic bars.

31. Limits of Elasticity.—A solid body which has been strained by considerable forces does not in general recover its original size and shape completely after the forces cease to act. The strain that is left is called set. If set occurs the elasticity is said to be "imperfect," and the greatest strain (or the greatest load) of any specified type, for which no set occurs, defines the "limit of perfect elasticity" corresponding to the specified type of strain, or of stress. All fluids and many solid bodies, such as glasses and crystals, as well as some metals (copper, lead, silver) appear to be perfectly elastic as regards change of volume within wide limits; but malleable metals and alloys can have their densities permanently increased by considerable pressures. The limits of perfect elasticity as regards change of shape, on the other hand, are very low. If they exist at all, for glasses and other hard, brittle solids; but a class of metals including copper, brass, steel, platinum are very perfectly elastic as regards distortion, provided that the distortion is not too great. The question can be tested by observation of the torsional elasticity of thin fibres or wires. The limits of perfect elasticity are somewhat ill-defined, because an experiment cannot warrant us in asserting that there is no set, but only that, if there is any set, it is too small to be observed.

32. A different meaning may be, and often is, attached to the phrase "limits of elasticity" in consequence of the following experimental result:—Let a bar be held stretched under a moderate tension, and let the extension be measured; let the tension be slightly increased and the extension again measured; let this process be continued, the tension being increased by equal increments. It is found that when the tension is not too great the extension increases by equal increments (as nearly as experiment can decide), but that, as the tension increases, a stage is reached in which the extension increases faster than it would do if it continued to be proportional to the tension. The beginning of this stage is tolerably well marked. Some time before this stage is reached the limit of perfect elasticity is passed; that is to say, if the load is removed it is found that there is some permanent set. The limiting tension beyond which the above law of proportionality fails is often called the "limit of linear elasticity." It is higher than the limit of perfect elasticity. For steel bars of various qualities L. Bauschinger found for this limit values varying from 10 to 17 tons per square inch. The result indicates that, when forces which produce any kind of strain are applied to a solid body and are gradually increased, the strain at any instant increases proportionally to the forces up to a stage beyond that at which, if the forces were removed, the body would completely recover its original size and shape, but that the increase of strain ceases to be proportional to the increase of load when the load surpasses a certain limit. There would thus be, for any type of strain, a limit of linear elasticity, which exceeds the limit of perfect elasticity.

33. A body which has been strained beyond the limit of linear elasticity is often said to have suffered an "over-strain." When the load is removed, the set which can be observed is not entirely permanent; but it gradually diminishes with lapse of time. This phenomenon is named "elastic after-working." If, on the other hand, the load is maintained constant, the strain is gradually increased. This effect indicates a gradual flowing of solid bodies under great stress; and a similar effect was observed in the experiments of H. Tresca on the punching and crushing of metals. It appears that all solid bodies under such great loads become "plastic." The elastic after-working, or "plastic," as it is sometimes called, can take a set which gradually increases with the lapse of time. No plasticity is observed when the limit of linear elasticity is not exceeded.

34. The values of the elastic limits are affected by overstrain. If the load is maintained for some time, and then removed, the limit of linear elasticity is found to be higher than before. If the load is not maintained, but is removed and then reapplied, the limit is found to be lower than before. During a period of rest a test piece recovers its elasticity after overstrain.

35. The effects of repeated loading have been studied by A. Wöhler, J. Bauschinger, O. Reynolds and others. It has been found that, after many repetitions of rather rapidly alternating stress, pieces are fractured by loads which they have many times withstood. It is not certain whether the fracture
ELASTICITY

is in every case caused by the gradual growth of minute flaws from the beginning of the series of tests, or whether the elastic quality of the material suffers deterioration apart from such flaws. It appears, however, that the stress exceeds a certain limit, so long as the limit of linear elasticity is not exceeded, repeated loads and rapidly alternating loads do not produce failure of the material.

36. The question of the conditions of safety, or of the conditions in which rupture is produced, is one upon which there has been much speculation, but no completely satisfactory result has been obtained. It has been variously held that rupture occurs when the numerically greatest principal stress exceeds a certain limit, or when this stress is tension and exceeds a certain limit, or when the greatest difference of two principal stresses (called the "stress difference") exceeds a certain limit, or when the greatest extension or the greatest shearing strain or the greatest strain of any type exceeds a certain limit. Some of these hypotheses appear to have been disproved. It was held by G. F. Fitzgerald (Nature, Nov. 5, 1896) that rupture is not produced by pressure symmetrically applied all round a body, and this opinion has been confirmed by the recent experiments of A. Pöppel. This result disposes of the greatest stress hypothesis and also of the greatest strain hypothesis. The fact that short pillars can be crushed by longitudinal pressure disposes of the greatest tension hypothesis, for there is no tension in the pillar. The greatest extension hypothesis failed to satisfy some tests imposed by H. Wehage, who experimented with blocks of wrought iron subjected to equal pressures in two directions at right angles to each other. The greatest stress difference hypothesis and the greatest shearing strain hypothesis would lead to practically identical results, and these results have been held by J. J. Guest to accord well with his experiments on metal tubes subjected to various systems of combined stress; but these experiments and Guest's conclusion have been criticized adversely by O. Mohr, and the question cannot be regarded as settled. The fact seems to be that the conditions of rupture depend largely upon the nature of the test (tensional, torsional, flexural, or whatever it may be) that is applied to a specimen, and that no general formula holds for all kinds of tests. The best modern technical writings emphasize the importance of the limits of linear elasticity and of tests of dynamical resistance (§ 87 below) as well as of statical resistance.

37. The question of the conditions of rupture belongs rather to the science of the strength of materials than to the science of elasticity itself; but it has been necessary to refer to it briefly here, because there is no method except the methods of the theory of elasticity for determining the state of stress or strain in a body subjected to forces. Whatever view may ultimately be adopted as to the relation between the conditions of safety of a structure and the state of stress or strain in it, the calculation of this state by means of the theory or by experimental means (as in § 18) cannot be dispensed with.

38. Methods of determining the Stress in a Body subjected to given Forces.—To determine the state of stress, or the state of strain, in an isotropic solid body strained within its limits of elasticity by given forces, we have to use (i.) the equations of equilibrium, (ii.) the equations of the bounding surface, (iii.) the relations between stress-components and strain-components, and (iv.) the relations between strain-components and displacement. The equations of equilibrium (ii.) are (with notation already used) three partial differential equations of the type

\[ \lambda + \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) + \frac{\partial}{\partial y} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) + \frac{\partial}{\partial z} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) = \alpha X - \beta X, \]

(3)

and three boundary conditions of the type

\[ \lambda \cos(x, y) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) + \mu \left( 2 \cos(x, y) + \cos(x, y) \frac{\partial u}{\partial x} + \cos(y, z) \frac{\partial v}{\partial y} + \cos(y, x) \frac{\partial w}{\partial z} \right) = \alpha X, \]

(4)

In the alternative method we eliminate the strain-components and the displacements. This method leads to a system of partial differential equations which is satisfied by the stress-components. In this system there are three equations of the type

\[ \frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 X}{\partial y^2} + \frac{\partial^2 X}{\partial z^2} = 0, \]

(1 bis)

three of the type

\[ \frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 Y}{\partial y^2} + \frac{\partial^2 Z}{\partial z^2} = 0, \]

(5)

and three of the type

\[ \frac{\partial^2 Y}{\partial x^2} + \frac{\partial^2 Y}{\partial y^2} + \frac{\partial^2 Z}{\partial z^2} = 0, \]

(6)

the equations of the two latter types being necessitated by the conditions of compatibility of strain-components. The solutions of these equations have to be adjusted so that the boundary conditions of the type (2) may be satisfied.

40. It is evident that whichever method is adopted the mathematical problem is in general very complicated. It is also evident that if we attempt to solve it by an integral expression as to the nature of the stress or strain, our intuition ought to satisfy the tests provided by the above systems of equations. Neglect of this precaution has led to many errors. Another source of frequent error lies in the neglect of the conditions in which the above systems of equations are correct. They are obtained by help of the supposition that the relative displacements of the parts of the strained body are equivalent. The solutions of them must therefore satisfy the test of smallness of the relative displacements.

41. Torsion.—As a first example of the application of the theory we take the problem of the torsion of prisms. This problem, considered first by C. A. Coulomb in 1784, was finally solved by B. de Saint-Venant in 1855. The problem is this:—

A cylindrical or prismatic bar is held twisted by terminal couples; it is required to determine the state of stress and strain in the interior. When the bar is a circular cylinder the problem is easy. Any section is displaced by rotation about the central-line through a small angle, which is proportional to the distance s of the section from a fixed plane at right angles to this line. This plane is a terminal section if one of the two terminal sections is not displaced. The angle through which the section s rotates is \( \tau s \), where \( \tau \) is a constant, called the amount of the twist; and this constant \( \tau \) is equal to \( G/\mu I \), where \( G \) is the twisting couple and \( I \) the moment of inertia of the cross-section about the central-line. This result is called "Coulomb's law." The stress within the bar is shearing stress, consisting, as it must, of two sets of equal tangential tractions on two sets of planes which are at right angles to each other. These planes are the cross-sections and the axial planes of the bar. The tangential traction at any point of the cross-section is directed at right angles to the axial plane through the point, and the tangential traction on the axial plane is directed parallel to the length of the bar. The amount of either of a distance \( \tau \) from the axis is \( \mu r \) or \( G/\mu I \). The result that \( G = \mu I \) can be used to determine \( \mu \) experimentally, for \( r \) may be measured and \( G \) and \( I \) are known.

42. When the cross-section of the bar is not circular it is clear that this solution fails; for the existence of tangential traction, near the prismatic bounding surface, on any plane which does not cut this surface at right angles, implies the existence of traction applied to this surface. We may attempt to modify the theory by retaining the supposition that the stress consists of shearing stress, involving tangential traction distributed in some way over the cross-sections. Such traction is obviously a necessary constituent of any stress-system which could be produced by terminal couples around the axis.
ELASTICITY

We should then know that there must be equal tangential
traction directed along the length of the bar, and exerted across
some planes or others which are parallel to this direction. We
should also know that, at the bounding surface, these planes
must cut this surface at right angles. The corresponding strain
would be shearing strain which could involve (i) a sliding
elements of one cross-section relative to another, (ii) a relative
sliding of elements of the above mentioned planes in the direction
of the length of the bar. We could conclude that there may be
a longitudinal displacement of the elements of the cross-
sections. We should then attempt to satisfy the conditions of
the problem by supposing that this is the character of the
strain, and that the corresponding displacement consists of
(i) a rotation of the cross-sections in their planes such as we
found in the case of the circle, (ii) a distortion of the cross-
sections into curved surfaces by a displacement \( \omega \) which is
directed normally to their planes and varies in some manner
from point to point of these planes. We could show that all
the conditions of the problem are satisfied by this assumption,
provided that the longitudinal displacement \( \omega \), considered as
a function of the position of a point \((x,y)\) in the cross-section,
satisfies the equation

\[
\frac{\partial \omega}{\partial x} + \frac{\partial \omega}{\partial y} = 0,
\]

and the boundary condition

\[
\left( \frac{\partial \omega}{\partial x} \right) \cos(x) + \left( \frac{\partial \omega}{\partial y} \right) \cos(y) = 0,
\]

where \( \tau \) denotes the amount of the twist, and \( \nu \) the direction
of the normal to the boundary. The solution is known for a
great many forms of section. (In the particular case of a circular
section \( \omega \) vanishes.) The tangential traction at any point of
the cross-section is directed along the tangent to that curve
of the family \( \psi = \text{const.} \) which passes through the point, \( \psi \) being
the function determined by the equations

\[
\frac{\partial \omega}{\partial x} = \tau \frac{\partial \psi}{\partial x}, \quad \frac{\partial \omega}{\partial y} = \tau \frac{\partial \psi}{\partial y}.
\]

The amount of the twist \( \tau \) produced by terminal couples of
magnitude \( G \) is \( \psi = \text{const.} \), where \( C \) is a constant, called the "toroidal
rigidity" of the prism, and expressed by the formula

\[
C = \mu \iint \left\{ \frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial y} \right\} \, dx \, dy,
\]

the integration being taken over the cross-section. When
the coefficient of \( \mu \) in the expression for \( C \) is known for any
section, \( \mu \) can be determined by experiment with a bar of that
form of section.

43. The distortion of the cross-sections into curved surfaces
is shown graphically by drawing the contour lines \((\omega = \text{const.})\).
In general the section is divided into a number of compartments,
and the portions that lie within two adjacent compartments
are respectively concave and convex. This result is
illustrated in the accompanying figures

(fig. 4 for the ellipse,
given by \( x^2/a^2 + y^2/b^2 = 1 \);
fig. 5 for the equilateral
triangle, given by \((x+1)(x-3y - \frac{1}{2}ax + \frac{3}{2}) = 0\);
fig. 6 for the square).

44. The distribution of the
shearing stress over the
cross-section is de-
determined by the function \( \psi \) already introduced. If we
draw the curve \( \psi = \text{const.} \), corresponding to any form of
section, for equidistant values of the constant, the tangential
traction at any point on the cross-section is directed along
the tangent to that curve of the family which passes through
the point, and the magnitude of it is inversely proportional to the
distance between consecutive curves of the family. Fig. 7
illustrates the result in the case of the equilateral triangle. The
boundary is, of course, one of the lines. The "lines of shearing
stress" which can thus be drawn are in every case identical
with the lines of flow of frictionless liquid filling a cylindrical
vessel of the same cross-section as the bar, when the liquid
circulates in the plane of the section with uniform spin. They
are also the same as the contour lines of a flexible and slightly
extensible membrane, of which the edge has the
same form as the bounding curve of the cross-section of the
bar, when the membrane is fixed at the edge
and slightly deformed by
uniform pressure.

Fig. 5

Fig. 6

Fig. 7
permanent set is produced by torsion. In the case of a section of any form, the strain and stress are greatest at points on the contour, and these points are in many cases the points of which the contour which are nearest to the centroid of the section. The theory has also been applied to show that a longitudinal flaw near the axis of a shaft transmitting a torsional couple has little influence on the strength of the shaft, but that in the neighbourhood of a similar flaw which is much nearer to the surface than to the axis the shearing strain may be nearly doubled, and thus the possibility of such flaws is a source of weakness against which special provision ought to be made.

46. Bending of Beams.—As a second example of the application of the general theory we take the problem of the flexure of a beam. In this case also we begin by forming a simple intuition as to the nature of the strain and the stress. On the side of the beam towards the center of curvature the longitudinal filaments must be contracted, and on the other side they must be extended. If we assume that the cross-sections remain plane, and that the central-line is unaltered in length, we see (at once from fig. 10) that the extensions (or contractions) are given by the formula \( \frac{y}{R} \), where \( y \) denotes the distance of a longitudinal filament from the plane drawn through the unstrained central-line at right-angles to the plane of bending, and \( R \) is the radius of curvature of the curve into which this line is bent (shown by the dotted line in the figure). Corresponding to this strain there must be a traction acting across the cross-sections. If we assume that there is no other stress, then the magnitude of the traction in question is \( E \frac{y}{R} \), where \( E \) is Young's modulus, and it is tension on the side where the filaments are extended and pressure on the side where they are contracted. If the plane of bending contains a set of principal axes of the cross-sections at their centroids, these tractions for the whole cross-section are equivalent to a couple of moment \( E \frac{y}{R} \), where \( I \) denotes the moment of inertia of the cross-section about an axis through its centroid at right angles to the plane of bending, and the plane of the couple is the plane of bending. Thus a beam of any form of section can be held bent in a "principal plane" by terminal couples of moment \( M \), that is to say by a "bending moment" \( M \); the central-line will take a curvature \( M/EI \), so that it becomes an arc of a circle of radius \( EI/M \); and the stress at any point will be tension of amount \( My/I \), where \( y \) denotes distance (reckoned positive towards the side remote from the centre of curvature) from that plane which initially contains the central-line and is at right angles to the plane of the couple. This plane is called the "neutral plane." The restriction that the beam is bent in a principal plane means that the plane of bending contains one set of principal axes of the cross-sections at their centroids; in the case of a beam of rectangular section the plane would bisect two opposite edges at right angles. In order that the theory may hold good the radius of curvature must be very large.

47. In this problem of the bending of a beam by terminal couples the stress is tension, determined as above, and the corresponding strain consists therefore of longitudinal extension of amount \( My/EI \) or \( y/R \) (contraction if \( y \) is negative), accompanied by lateral contraction of amount \( yM/EI \) or \( yR \) (extension if \( y \) is negative), \( \sigma \) being Poisson's ratio for the material. Our intuition of the nature of the strain was imperfect, inasmuch as it took no account of these lateral strains. The necessity for introducing them was pointed out by Saint-Venant. The effect of them is a change of shape of the cross-sections in their own planes. This is shown in an exaggerated way in fig. 10, where the rectangle ABCD represents the cross-section of the unstrained beam, or a rectangular portion of this cross-section, and the curvilinear figure A'B'C'D' represents an exaggerated fashion the cross-section (or the corresponding portion of the cross-section) of the same beam, when bent so that the centre of curvature of the central-line (which is at right angles to the plane of the figure) is on the line EF produced beyond F. The lines A'B' and C'D' are approximately circles of radii \( R/\sigma \), when the central-line is a circle of radius \( R \), and their centres are on the line EF produced beyond E. Thus the neutral plane, and each of the faces that is parallel to it, becomes strained into an antilastic surface, whose principal curvatures are in the ratio \( \sigma : 1 \). The general appearance of the bent beam is shown in an exaggerated fashion in fig. 11, where the traces of the surface into which the neutral plane is bent are dotted. The result is that the ratio of the principal curvatures of the antilastic surfaces, into which the top and bottom planes of the beam (of rectangular section) are bent, is Poisson's ratio \( \sigma \), which has been used for the experimental determination of \( \sigma \). The result that the radius of curvature of the bent central-line is \( EI/M \) is used in the experimental determination of \( E \). The quantity \( EI \) is often called the "flexural rigidity" of the beam. There are two principal flexural rigidities corresponding to bending in the two principal planes (cf. § 62 below).

48. That this theory requires modification, when the load does not consist simply of terminal couples, can be seen most easily by considering the problem of a beam loaded at one end with a weight \( W \), and supported in a horizontal position at its other end. The forces that are exerted at any section \( p \), to balance the weight \( W \), must reduce statically to a vertical force \( W \) and a couple, and these forces arise from the action of the part \( Ap \) on the part \( Bp \) (see fig. 12), i.e. from the stresses across the section at \( p \). The couple is equal to the moment of the applied load \( W \) about an axis drawn through the centroid of the section \( p \) at right angles to the plane of bending. This moment is called the "bending moment" at the section, it is the product of the load \( W \) and the distance of the section from the loaded end, so that it varies uniformly along the length of the beam. The stress that suffices in the simpler problem gives rise to no vertical force, and it is clear that in addition to longitudinal tensions and pressures there must be tangential tractions on the cross-sections. The resultant of these tangential tractions must be a force equal to \( W \), and directed vertically;
but the direction of the traction at a point of the cross-section need not in general be vertical. The existence of tangential traction on the cross-section implies the existence of equal tangential traction, directed parallel to the central-line, on some planes or other which are parallel to this line, the two sets of tractions forming a shearing stress. We conclude that such shearing stress is a necessary constituent of the stress-system in the beam bent by terminal transverse load. We can develop a theory of this stress-system from the assumptions (1) that the tension at any point of the cross-section is related to the bending moment at the section by the same law as in the case of uniform bending by terminal couples; (2) that, in addition to this tension, there is at any point shearing stress, involving tangential tractions acting in appropriate directions upon the elements of the cross-sections. When these assumptions are made it appears that there is one and only one distribution of shearing stress by which the conditions of the problem can be satisfied. The determination of the amount and direction of this shearing stress, and of the corresponding strains and displacements, was effected by Saint-Venant and R. F. A. Clebsch for a number of forms of section by means of an analysis of the same kind as that employed in the solution of the torsion problem.

50. The expressions for the shearing stresses depend on the shape of the cross-section. Taking the beam to be of isotropic material, and the cross-section to be an ellipse of semi-axes and , and drawing the axes at right angles to the plane of flexure, we find that the vertical shearing stress at any point of the cross-section is

\[ W_{y} = \frac{W(1 - \frac{a}{b})}{\pi a b} \left( \frac{x}{a} \right) \left( \frac{y}{b} \right) \]

The resultant of these stresses is , but the amount at the centroid, which is the maximum amount, exceeds the average amount, by the ratio

\[ \frac{1}{\pi} \left( \frac{a}{b} \right) \left( \frac{x}{a} \right) \left( \frac{y}{b} \right) \]

If , this ratio is , for a circle, nearly for a flat elliptic bar with the longest diameter vertical, nearly for a flat elliptic bar with the longest diameter horizontal.

In the same problem the horizontal shearing stress at any point of the cross-section is of amount

\[ W_{x} = \frac{W a (1 + \frac{a}{b}) + b}{\pi a b} \left( \frac{x}{a} \right) \left( \frac{y}{b} \right) \]

The resultant of these stresses vanishes; but, taking as before , and putting for the three cases above , , and , we find that the ratio of the maximum of this stress to the average vertical shearing stress has the values , nearly , and nearly . Thus the stress is of considerable importance when the beam is a plank. As another example we may consider a circular tube of external radius and internal radius . Writing , we find

\[ P = \frac{4W}{\pi (r_0 - r_1)} \left( \frac{x}{r_0} \right) \left( \frac{y}{r_1} \right) \]

\[ U = \frac{2(1 + x) \pi (r_0 - r_1)^2 (3 + 2e)}{(r_0 + r_1) (r_0 - r_1)} \left( \frac{x}{r_0} \right) \left( \frac{y}{r_1} \right) \]

\[ T = \frac{4W}{\pi (r_0 - r_1)} \left( \frac{x}{r_0} \right) \left( \frac{y}{r_1} \right) \left( \frac{z}{r_2} \right) \]

and for a tube of radius and small thickness the value of and the maximum values of and reduce approximately to

\[ P = -\frac{W(1 - x) y}{r_0 r_1} \]

\[ U_{\text{max}} = \frac{W}{r_0}, U_{\text{max}} = \frac{W}{2r_1} \]

The greatest value of in this case approximately twice its average value, but it is possible that these results for the bending of very thin tubes may be seriously at fault if the tube is not plugged, and if the load is not applied in the manner contemplated in the theory (cf. § 53). In such cases the extensions and contractions of the longitudinal filaments may be practically confined to a small part of the material near the ends of the tube, while the rest of the tube is deformed without noticing it.

51. The tangential tractions , at any point of the cross-sections are necessarily accompanied by tangential tractions on the longitudinal sections, and on each such section the tangential traction is parallel to the central line; on a vertical section , and on a horizontal section , its amount at any point is , and on a horizontal section , its amount at any point is . The internal stress at any point is completely determined by the components , , and compound , into a resultant represented by ; the plane is a principal plane of stress at , and the principal stress at right angles to this plane vanishes. Take the middle point of , and centre and radius . Then the principal stresses , and can be obtained from the general geometrical constructions for determining the principal stresses at any point when the values of , , are known.

From the point (fig. 14) draw lines , , , to represent the stresses , , at , on the cross-section through , in magnitude, direction and sense, and compound , and , into a resultant represented by ; the plane is a principal plane of stress at , and the principal stress at right angles to this plane vanishes. Take the middle point of , and centre , and radius . Then and represent the major and minor principal stresses of the two remaining principal stresses. On describe a rectangle ABCD so that BC passes through ; then OC is the direction of the principal stress represented in magnitude by , and OD is the direction of the principal stress represented in magnitude by .

52. As regards the strain in the beam, the longitudinal and lateral extensions and contractions depend on the bending moment in the same way as in the simpler problem; but, the bending moment being variable, the antilastic curvature produced is also variable. In addition to these extensions and contractions there are shearing strains corresponding to the shearing stresses , . The shearing strain corresponding to consists of a relative sliding parallel to the central-line of different longitudinal linear elements combined with a relative sliding in a transverse horizontal direction of elements of different cross-sections; the latter of these is caused in the production of those displacements by which the variable antilastic curvature is brought about; to see the effect of the former we may most suitably consider, for the case of an elliptic cross-section, the distortion of the shape of a rectangular portion of a plane of the material which in the natural state was horizontal; all the boundaries of such a portion become parabolas of small curvature, which is variable along the length of the beam, and the particular effect under consideration is the change of the transverse horizontal linear elements from straight lines such as to parabolas such as (fig. 15); the lines and are parallel to the central-line, and the figure is drawn for a plane above the neutral plane. When the cross-section is not an ellipse the character of the strain is the same, but the curves are only approximately parabolic.

The shearing strain corresponding to is a distortion which has the effect that the straight vertical filaments become curved lines which cut the longitudinal filaments obliquely, and thus the cross-sections do not remain plane, but become curved surfaces, and the tangent plane to any one of these surfaces at the centroid cuts the central line obliquely (fig. 16). The angle between these tangent planes and the central-line is the same at all points of the line; and, if it is denoted by , the value of is expressible as
and it depends on the shape of the cross-section; for the elliptic section of \( \frac{1}{2} \) its value is
\[
\frac{4W}{Ea^{\theta}(1+\nu)+b^{\theta}}
\]

for a circle (with \( \sigma = 1 \)) this becomes \( 7W/\pi Ea^{\theta} \). The vertical filament through the centroid of any cross-section becomes a cubical parabola, as shown in fig. 16, and the contour lines of the curved surface into which any cross-section is distorted are shown in fig. 17 for a circular section.

53. The deflection of the beam is determined from the equation

\[
\text{curvature of central line = bending moment + flexural rigidity}
\]

and the special conditions at the supported end; there is no alteration of this statement on account of the shears. As regards the special condition at an end which is unstiffened, or built in, Saint-Venant proposed to assume that the central tangent plane of the cross-section at the end is vertical; with this assumption the tangent to the central line at the end is inclined downwards and makes an angle \( \theta \) with the horizontal (see fig. 18); it is, however, improbable that this condition is exactly realized in practice. In the application of the theory to the experimental determination of Young's modulus, the small angle which the central line at the support makes with the horizontal is an unknown quantity, to be eliminated by observation of the deflection at two or more points.

54. We may suppose the displacement in a bent beam to be produced by the following operations: (1) the central-line is deflected into its curved form, (2) the cross-sections are rotated about axes through their centroids at right angles to the plane of flexure so as to make angles equal to \( \pi + \theta \) with the central-line, (3) each cross-section is distorted in its own plane in such a way that the appropriate variable antischliss curvature is produced, (4) the cross-sections are further distorted into curved surfaces. The contour lines of fig. 17 show the disturbance from the central tangent plane, not from the original vertical plane.

55. Practical Application of Saint-Venant's Theory.—The theory above described is exact provided the forces applied to the loaded end, which have \( W \) for resultant, are distributed over the terminal section in a particular way, not likely to be realized in practice; and the application to practical problems depends on a principle due to Saint-Venant, to the effect that, except for comparatively small portions of the beam near to the loaded and fixed ends, the resultant only is effective, and its mode of distribution does not seriously affect the internal strain and stress. In fact, the actual stress is that due to forces with the required resultant distributed in the manner contemplated in the theory, superposed upon that due to a certain distribution of forces on each terminal section which, if applied to a rigid body, would keep it in equilibrium; according to Saint-Venant's principle, the stresses and strains due to such distributions of force are unimportant except near the ends. For this principle to be exactly applicable it is necessary that the length of the beam should be very great compared with any linear dimension of its cross-section; for the practical application it is sufficient that the length should be about ten times the greatest diameter.

In recent years the problem of the bending of a beam by loads distributed along its length has been much advanced. It is now practically solved for the case of a load distributed uniformly, or according to any rational algebraic law, and it is also solved for the case where the thickness is small compared with the length and depth, as in a plate girder, and the load is distributed in any way. These solutions are rather complicated and difficult to interpret. The case which has been worked out most fully is that of a transverse load distributed uniformly along the length of the beam. In this case two noteworthy results have been obtained. The first of these is that the central-line in general suffers extension. This result had been found experimentally many years before. In the case of the plate girder loaded uniformly along the top, this extension is just half as great as the extension of the central-line of the same girder when free at the ends, supported along the base, and carrying the same load along the top. The second noteworthy result is that the curvature of the central-line is not proportional to the bending moment. Over and above the curvature which would be found from the ordinary relation—

\[
\text{curvature of central-line = bending moment + flexural rigidity}
\]

there is an additional curvature which is the same at all the cross-sections. In ordinary cases, provided the length is large compared with any linear dimension of the cross-section, this additional curvature is small compared with that calculated from the ordinary formula, but it may become important in cases like that of suspension bridges, where a load carried along the middle of the roadway is supported by tennons in rods attached at the sides.

57. When the ordinary relation between the curvature and the bending moment is applied to the calculation of the deformation of continuous beams it must not be forgotten that a correction of the above just mentioned may possibly be requisite. In the usual method of treating the problem such corrections are not considered, and the ordinary relation is made the basis of the theory. In order to apply this relation to the calculation of the deflection, it is necessary to know the bending moment at every point; and, since the pressures of the supports are not among the data of the problem, we require a method of determining the bending moments at the supports either by calculation or in some other way. The calculation of the bending moment can be replaced by a method of graphical construction, due to Mohr, and depending on the two following theorems:

(i.) The curve of the central-line of each span of a beam, when the bending moment \( M \) is given, is identical with the catenary or funicular curve passing through the ends of the span under a (fictitious) load per unit length of the span equal to \( M/EI \), the horizontal tension in the funicular being unity.

(ii.) The directions of the tangents to this funicular curve at the ends of the span are the same for all statically equivalent systems of (fictitious) load.

When \( M \) is known, the magnitude of the resultant shearing stress at any section is \( dM/dx \), where \( x \) is measured along the beam.

The sign of \( M \) is shown by the arrow-heads in fig. 19, for which, with \( y \) downwards,

\[
EJ\frac{d^2y}{dx^2} + M = 0.
\]
ELASTICITY

58. Let \( L \) be the length of a span of a loaded beam (fig. 19). \( M_1 \) and \( M_2 \) bending moments at the ends, \( M \) the bending moment at a section distant \( x \) from the end \((M_1)\), \( M' \) the bending moment at the same section when the same span with the same load is simply supported; then \( M \) is given by the formula

\[
M = M_1 + \frac{1}{E} \frac{L}{I} M_2.
\]

and thus a fictitious load statically equivalent to \( M/EI \) can be easily found when \( M' \) has been found. If we draw a curve (fig. 20) to pass through the ends of the span, so that its ordinate represents the value of \( M'/EI \), the corresponding fictitious loads are statically equivalent to a single load, of amount represented by the area of the curve, placed at the point of the span vertically above the centre of gravity of this area.

If \( P \) is the ordinate of this curve, and if at the ends of the span we erect ordinates in the proper sense to represent \( M_1/EI \) and \( M_2/EI \), the bending moment at any point is represented by the length \( P \).

For a uniformly distributed load the curve of \( M' \) is a parabola \( M' = \frac{wL^2}{2}(1-\frac{x}{L}) \), where \( w \) is the load per unit of length; and the statically equivalent fictitious load is \( \frac{wL}{E} \) placed at the middle point \( G \) of the span; also the loads statically equivalent to the fictitious loads \( M_1(L-x)/EI \) and \( M_2/EI \) are \( \frac{wL}{E} \) and \( \frac{wL}{2E} \) respectively.

The centre of gravity of the two latter is a fixed point independent of \( M_0 \), and the line \( VK \) of the figure is the vertical through this point. We draw \( AD \) and \( CE \) to represent the loads at \( G \); \( G' \) in magnitude; then \( D \) and \( E \) are fixed points. We construct any triangle \( UVW \) whose sides \( UV, \) \( UW \) pass through \( D, \) \( B, \) and whose vertices lie on the verticals \( gU, \) \( gK, \) \( gW; \) the point \( F \) where \( VW \) meets \( DB \) is a fixed

\[ \frac{1}{E_1} \frac{1}{g} \]

this appears from the diagrams of forces, fig. 22, in which the oblique lines are marked to correspond to the sides of the fictorials to which they are parallel.

In the application of the method to more complicated cases there are two systems of fixed points corresponding to \( F, \) by means of which the sides of the fictorials are drawn.

60. Finite Bending of Thin Rod.—The equation curvature = bending moment + flexural rigidity may also be applied to the problem of the flexure in a principal plane of a very thin rod or wire, for which the curvature need not be small. When the forces that produce the flexure are applied at the ends only, the curve into which the central-line is bent is one of a definite family of curves, to which the name elastic has been given, and there is a division of the family into two species according as the external forces are applied directly to the ends or are applied to rigid arms attached to the ends; the curves of the former species are characterized by the presence of inflections at all the points at which they cut the line of action of the applied forces.

We select this case for consideration. The problem of determining the form of the curve (fig. 23) is mathematically identical with the problem of determining the motion of a simple circular pendulum oscillating through a finite angle, as is seen by comparing the differential equation of the curve

\[
\frac{d^2 \phi}{dt^2} + g \sin \phi = 0
\]

with the equation of motion of the pendulum

\[
\frac{d^2 \phi}{dt^2} + g \sin \phi = 0.
\]

The length \( L \) of the curve between two inflections corresponds to the time of oscillation of the pendulum from rest to rest, and we thus have

\[
L \sqrt{\frac{W}{EI}} = 2K,
\]

where \( K \) is the real quarter period of elliptic functions of modulus \( \sin \phi, \) and \( \phi \) is the angle at which the curve cuts the line of action of the applied forces. Unless the length of the rod exceeds the real period of oscillation \( \sqrt{EI/W} \) it will not bend under the force, but when the length is great enough there may be more than two points of inflection and more than one bay of the curve; for \( n \) bays \( (n+1) \) inflections the length must exceed \( n \sqrt{EI/W} \).

Some of the forms of the curve are shown in fig. 24.

For the form \( d, \) in which two bays make a figure of eight, we have

\[
L \sqrt{\frac{W}{EI}} = 4.6, \phi = 130^\circ
\]

approximately. It is noteworthy that whenever the length and force admit of a sinusuous form, such as \( a \) or \( b, \) with more than two inflections, there is also possible a crossed form, like \( e, \) with two inflections only; the latter form is stable and the former unstable.

61. The particular case of the above for which \( a \) is very small is a curve of sines of small amplitude, and the result in this case has been applied to the problem of the buckling of struts under thrust. When the strut, of length \( L', \) is...
maintained upright at its lower end, and loaded at its upper end, it is simply contracted, unless \( L^{\pi}W > \pi^{2}EI \), for the lower end corresponds to a point at which the tangent is vertical on an elastic for which the line of inflections is also vertical, and thus the length must be half of one bay (fig. 25, a).

For greater lengths or loads the strut tends to bend or buckle under the load. For a very slight excess of \( L^{\pi}W \) above \( \frac{1}{\pi^{2}}EI \), the theory on which the above discussion is founded, is not quite adequate, as it assumes the central-line of the strut to be free from extension or contraction, and it is probable that bending without extension does not take place when the length or the force exceeds the critical value but slightly. It should be noted also that the formula has no application to short struts, as the theory from which it is derived is founded on the assumption that the length is great compared with the diameter (cf. § 56).

The condition of buckling, corresponding to the above, for a long strut, of length \( L \), when both ends are free to turn is \( L^{\pi}W > \pi^{2}EI \); for the central-line forms a complete bay (fig. 25, b); if both ends are maintained in the same vertical line, the condition is \( L^{\pi}W > 4\pi^{2}EI \), the central-line forming a complete bay and two half bays (fig. 25, c).

62. In our consideration of flexure it has so far been supposed that the bending takes place in a principal plane. We may remove this restriction by resolving the forces that tend to produce bending into systems of forces acting in the two principal planes. To each plane there corresponds a particular flexural rigidity, and the systems of forces in the two planes give rise to independent systems of stress, strain and displacement, which must be superposed in order to obtain the actual state. Applying this process to the problem of §§ 48-54, and supposing that one principal axis of a cross-section at its centroid makes an angle \( \theta \) with the vertical, then for any shape of section the neutral surface or locus of unextended fibres cuts the section in a line \( DD' \), which is conjugate to the vertical diameter \( CP \) with respect to any ellipse of inertia of the section. The central-line is bent into a plane curve which is not in a vertical plane, but is in a plane through the line \( CV \) which is perpendicular to \( DD' \) (fig. 26).

63. Bending and Twisting of Thin Rods.—When a very thin rod or wire is bent and twisted by applied forces, the forces on any part of it or a wire is bent and twisted by applied forces, the forces on any part of it or a wire are balanced by the tractions across the section, and these tractions are statically equivalent to certain forces and couples at the centroid of the section; we shall call them the stress-resultants and the stress-couples. The stress-couples consist of two flexural couples in the two principal planes, and the torsional couple about the tangent to the central-line. The torsional couple is the product of the torsional rigidity and the twist produced; the torsional rigidity is exactly the same as for a straight rod of the same material and section twisted without bending, as in Saint-Venant's torsion problem (§ 42). The twist \( \tau \) is connected with the deformation of the wire in this way: if we suppose a very small ring which fits the cross-section of the wire to be provided with a pointer in the direction of one principal axis of the section at its centroid, and to move along the wire with velocity \( v \), the pointer will rotate about the central-line with angular velocity \( \tau \).

The amount of the flexural couple for either principal plane at any section is the product of the flexural rigidity for that plane, and the resolved part in that plane of the curvature of the central line at the centroid of the section; the resolved part of the curvature along the normal to any plane is obtained by treating the curvature as a vector directed along the normal to the osculating plane and projecting this vector. The flexural couples reduce to a single couple in the osculating plane proportional to the curvature when the two flexural rigidities are equal, and in this case only.

The stress-resultants across any section are tangential forces in the two principal planes, and a tension or thrust along the central-line; when the stress-couples and the applied forces are known these stress-resultants are determinate. The existence, in particular, of the resultant tension or thrust parallel to the central-line does not imply sensible extension or contraction of the central filament, and the tension per unit area of the cross-section to which it would be equivalent is small compared with the tensions and pressures in longitudinal filaments not passing through the centroid of the section; the moments of the latter tensions and pressures constitute the flexural couples.

64. We consider, in particular, the case of a naturally straight spring or rod of circular section, radius \( c \), and of homogeneous isotropic material. The torsional rigidity is \( \frac{1}{2}Ec^{3}/(1+\sigma) \); and the flexural rigidity, which is the same for all planes through the central-line, is \( \frac{1}{2}Ec^{3} \); we shall denote these by \( C \) and \( A \) respectively. The rod may be held bent by suitable forces into a curve of double curvature with an amount of twist \( \tau \), and then the torsional couple is \( C\tau \), and the flexural couple in the osculating plane is \( A\rho \), where \( \rho \) is the radius of circular curvature. Among the curves in which the rod can be held by forces and couples applied at its ends only, one is a circular helix; and then the applied forces and couples are equivalent to a wrench about the axis of the helix.

Let \( \rho \) be the radius of the helix, so that \( \rho = \rho \cos \alpha \), and let \( R \) and \( K \) be the force and couple of the wrench (fig. 27). Then the couple formed by \( R \) and an equal and opposite force at any section and the couple \( K \) are equivalent to the torsional and flexural couples at the section, and this gives the equations for \( R \) and \( K \):

\[
R = A\sin \alpha \cos^{2} \alpha - C\cos \alpha \sin \alpha,
\]

\[
K = A\cos^{2} \alpha + C\sin \alpha.
\]

The thrust across any section is \( R \sin \alpha \) parallel to the tangent to the helix, and the shearing stress-resultant is \( R \cos \alpha \) at right angles to the osculating plane.

When the twist is such that, if the rod were simply bent, it
would also be un twisted, \( r = (\sin a \cos a) / r \), and then, restoring the values of A and C, we have

\[
R = \frac{E r c^4 \sigma}{4 \pi^2 \frac{1}{r} \cos^4 a},
\]

\[
K = \frac{E r c^4 \frac{1}{r} + \cos^2 a}{4 \pi^2 \frac{1}{r} \cos^2 a}.
\]

65. The theory of spiral springs affords an application of these results. The stress-couples called into play when a naturally helical spring \((a, r)\) is held in the form of a helix \((a', r')\), are equal to the differences between those called into play when a straight rod of the same material and section is held in the first form, and those called into play when it is held in the second form.

Thus the torsional couple is

\[
C \left( \sin a' \cos a' - \sin a \cos a \right),
\]

and the flexural couple is

\[
A \left( \frac{\cos^2 a' - \cos^2 a}{r} \right).
\]

The wrench \((R, K)\) along the axis by which the spring can be held in the form \((a', r')\) is given by the equations

\[
R = A \left( \frac{\sin a' \cos^2 a' - \cos^2 a}{r} \right) - C \cos a' \left( \frac{\sin a' \cos a'}{r} + \sin a \cos a \right),
\]

\[
K = A \left( \frac{\cos a' \cos^2 a' - \cos^2 a}{r} \right) + C \sin a' \left( \frac{\sin a' \cos a'}{r} - \sin a \cos a \right).
\]

When the spring is slightly extended by an axial force \(F = -R\), and there is no couple, so that \(K\) vanishes, and \(a', r'\) differ very little from \(a, r\), it follows from these equations that the axial elongation, \(\delta c\), is connected with the axial length \(x\) and the force \(F\) by the equation

\[
F = \frac{E r c^4 \sin a}{4 \pi^2 \frac{1}{r} + \cos^2 a} \frac{\delta c}{x},
\]

and that the loaded end is rotated about the axis of the helix through a small angle

\[
\frac{4 \pi E F r c^4}{E r c^4 \cos a},
\]

the sense of the rotation being such that the spring becomes more tightly coiled.

66. A horizontal pointer attached to a vertical spiral spring would be made to rotate by loading the spring, and the angle through which it turns might be used to measure the load, at any rate, when the load is not too great; but a much more sensitive contrivance is the twisted strip devised by W. E. Ayrton and J. Perry. A very thin, narrow rectangular strip of metal is given a permanent twist about its longitudinal middle line, and a pointer is attached to it at right angles to this line. When the strip is subjected to longitudinal tension the pointer rotates through a considerable angle. G. H. Bryan (Phil. Mag., December 1890) has succeeded in constructing a theory of the action of the strip, according to which it is regarded as a strip of plate in the form of a right helicoid, which, after extension of the middle line, becomes a portion of a slightly different helicoid; on account of the thinness of the strip, the change of curvature of the surface is considerable, even when the extension is small, and the pointer turns with the generators of the helicoid.

If \(\beta\) stands for the breadth and \(l\) for the thickness of the strip, and \(r\) for the permanent twist, the approximate formula for the angle \(\delta\) through which the strip is untwisted on the application of a load \(W\) was found to be

\[
\delta = -\frac{W l r (1 + \epsilon)}{2E l r (1 + (1 + \epsilon) \frac{b r^2}{l})}.
\]

The quantity \(b r\) which occurs in the formula is the total twist in a length of the strip equal to its breadth, and this will generally be very small; if it is small of the same order as \(1/b\), or a higher order, the formula becomes \(W l r (1 + \epsilon) / E l r\), with sufficient approximation, and this result appears to be in agreement with observations of the behaviour of such strips.

67. Thin Plate under Pressure.—The theory of the deformation of plates, whether plane or curved, is very intricate, partly because of the complexity of the kinematical relations involved. We shall here indicate the nature of the effects produced in a thin plate plane, of isotropic material, which is slightly bent by pressure. This theory should have an application to the stress produced in a ship's plates. In the problem of the cylinder under internal pressure (§ 77 below) the most important stress is the circumferential tension, counteracting the tendency of the circular filaments to expand under the pressure; but in the problem of a plane plate some of the filaments parallel to the plane of the plate are extended and others are contracted, so that the tensions and pressures along them give rise to resultant couples but not always to resultant forces. Whatever forces are applied to bend the plate, these couples are always expressible, at least approximately in terms of the principal curvatures produced in the surface which, before strain, was the middle plane of the plate. The simplest case is that of a rectangular plate, bent by a distribution of couples applied to its edges, so that the middle surface becomes a cylinder of large radius \(R\); the requisite couple per unit of length of the straight edges is of amount \(C/R\), where \(C\) is a certain constant; and the requisite couple per unit of length of the circular edges is of amount \(C/eR\), the latter being required to resist the tendency to antilastic curvature (cf. § 47). If normal sections of the plate are supposed drawn through the generators and circular sections of the cylinder, the action of the neighbouring portions on any portion so bounded involves flexural couples of the above amounts. When the plate is bent in any manner, the curvature produced at each section of the middle surface may be regarded as arising from the superposition of two cylindrical curvatures; and the flexural couples across normal sections through the lines of curvature, estimated per unit of length of those lines, are \(C'(x/R)\) and \(C(x/R)\), where \(R_u\) and \(R_v\) are the principal radii of curvature. The value of \(C\) for a plate of small thickness \(h\) is \(\sqrt{Eh}/(1 - \epsilon^2)\). Exactly as in the problem of the beam (§§ 48, 56), the action between neighbouring portions of the plate generally involves shearing stresses across normal sections as well as flexural couples; and the resultants of these stresses are determined by the conditions that, with the flexural couples, they balance the forces applied to the plate.

68. To express this theory analytically, let the middle plane of the plate in the unstrained position be taken as the plane of \((x, y)\), and let normal sections at right angles to the axes of \(x\) and \(y\) be drawn through any point. After strain let \(w\) be the displacement of this point in the direction perpendicular to the plane, marked \(\rho\) in fig. 28. If the axes of \(x\) and \(y\) were parallel to the lines of curvature at the point, the flexural couple acting across the section normal to \(x\) (or \(y\)) would have the axis of \(y\) (or \(x\)) for its axis; but when the lines of curvature are inclined to the axes of co-ordinates, the flexural couple across a section normal to either axis has a component about that axis as well as a component about the perpendicular axis. Consider an element ABCD of the section at right angles to the axis of \(x\), contained between two lines near together and perpendicular to the middle plane. The action of the portion of the plate to the right upon the portion to the left, across the element, gives rise to a couple about the middle line \((y)\) of amount, estimated per unit of length of that line, equal to \(C_{x'} \frac{\partial y}{\partial x} + C_{y'} \frac{\partial x}{\partial y}\) = \(G_1\), say, and to a couple, similarly estimated, about the normal \(z\) of amount \(-C(1 - \epsilon) \frac{\partial y}{\partial x} - H\), say. The
corresponding couples on an element of a section at right angles
to the axis of , estimated per unit of length of the axis of , are
of amounts \(-C \frac{\partial^2 u}{\partial x^2} \), \(-G \frac{\partial^2 v}{\partial x \partial y} \), \(-G \frac{\partial^2 w}{\partial x^2} \), \(-C \frac{\partial^2 v}{\partial y^2} \), \(-G \frac{\partial^2 w}{\partial x \partial y} \), \(-C \frac{\partial^2 w}{\partial x \partial y} \). The resultant
shear force on the element is then found by the equation
\[ F = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 v}{\partial x \partial y} + \frac{\partial^2 w}{\partial x \partial y} + \frac{\partial^2 w}{\partial y^2} \]

This equation, together with the special conditions at the rim, suffices for the determination of \( F \), and then all the quantities here introduced are determined. Further, the most important of the stress-components are those which act across elements of normal sections: the tension in direction \( z \), at a distance \( z \) from the middle plane measured in the direction of \( p \), is of amount
\[ \frac{3C}{2a} \left( \frac{\partial^2 u}{\partial z^2} + i \cdot \frac{\partial^2 v}{\partial z^2} \right) \]
and there is a corresponding tension in direction \( \gamma \); the shearing stress consisting of traction parallel to \( \gamma \) on planes \( \sigma = \text{const.} \), and traction parallel to \( \sigma \) on planes \( \gamma = \text{const.} \), is of amount
\[ \frac{3C}{2a} \left( \frac{\partial^2 u}{\partial z^2} + \frac{\partial^2 v}{\partial z \partial \gamma} \right) \]
These tensions and shearing stresses are equivalent to two principal tensions, in the directions of the lines of curvature in the middle plane, and they give rise to the flexural couples. In the special example of a circular plate, of radius \( a \), supported at the rim, and having a uniform pressure \( p \) at its surface, the value of \( w \) at a point distant \( r \) from the axis is
\[ \frac{1}{4} \frac{E}{(a-r)^2} \left( 1 - \frac{r}{a} \right)^2 \]
and the most important of the stress components is the radial tension, of which the amount at any point is \( \frac{E}{(a-r)^2} \); the maximum radial tension is about \( \frac{E}{a^2} \), and, when the thickness of the plate is small compared with the diameter, this is a large multiple of \( p \).

General Theorems.—Passing now from these questions of flexure and torsion, we consider some results that can be deduced from the general equations of equilibrium of an elastic solid body.

The form of the general expression for the potential energy

\[ \frac{1}{2} \int \left( \frac{E}{a^2} \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 v}{\partial x \partial y} + \frac{\partial^2 w}{\partial x \partial y} + \frac{\partial^2 w}{\partial y^2} \right) \right) \]

The effects of forces applied at different points and in different directions can be obtained by summation, and the effect of continuously distributed forces can be obtained by integration.

The stress system considered in \( \S 71 \) is equivalent, on the plane through the origin at right angles to the line of action of \( F \), to a resultant pressure of magnitude \( |F| \) at the origin and a radial traction of amount \( \frac{F}{2(1-\nu)} \) and, by the application of this system of tractions to a solid bounded by a plane, the displacement just described would be produced. There is also another stress system for a solid so bounded which is equivalent, on the same plane, to a resultant pressure at the origin, and a radial traction proportional to \( F \).

The second stress system (see fig. 32) consists of:

1. \( \frac{F}{2(1-\nu)} \) acting at the point of application of the force.
2. \( \frac{F}{2(1-\nu)} \) acting at the point of application of the force.
3. The stress across the plane boundary consists of a resultant pressure of magnitude \( 2F \) and a radial traction of amount \( F \).

The line joining the points of contact must be normal to the planes.

Fig. 29.

Fig. 30.

Fig. 31.
ELASTICITY

then we superpose the component stresses of the last section multiplied by $\alpha(1-e)W/F$, and the component stresses here written down multiplied by $-(1-2\varepsilon)W/2\pi r^4 F$, the stress on the plane boundary will reduce to a single pressure $W$ at the origin. We shall henceforth state the system at any point due to such a force applied at one point of the boundary.

In the stress system thus arrived at the traction across any plane parallel to the boundary is directed away from the place where $W$ is supported, and its amount is $3W \cos \vartheta/2\pi r^4$. The corresponding displacement consists of

1. horizontal displacement radially outwards from the vertical through the origin of amount

$$W(1-\varepsilon) \sin \vartheta \cos \theta \cdot \frac{1}{2\pi r^4} \left( \cos \theta - 1 + \cos \theta \right).$$

2. a vertical displacement downwards of amount

$$W(1-\varepsilon) \cos \vartheta \cos \theta \cdot \frac{1}{2\pi r^4} \cos^2 \vartheta.$$

The effects produced by a system of loads on a solid bounded by a plane can be deduced.

The results for a solid body bounded by an infinite plane may be interpreted as giving the local effects of forces applied to a small part of the surface of a body. The results show that pressure is transmitted into a body from the boundary in such a way that the traction at a point on a section parallel to the plane is the same at all points of any sphere which touches the boundary at the point of pressure, and that its amount at any point is inversely proportional to the square of the radius of this sphere, while its direction is that of a line drawn from the point of pressure to the point at which the traction is estimated. The transmission of force through a solid body indicated by this result was strikingly demonstrated in an attempt that was made to measure the lunar deflexion of gravity; it was found that the weight of the observer on the floor of the laboratory produced a disturbance of the instrument sufficient to disguise completely the effect which the instrument had been designed to measure (see G. H. Darwin, The Tides and Kindred Phenomena in the Solar System, London, 1898).

73. There is a corresponding theory of two-dimensional systems, that is, to say, systems in which either the displacement is parallel to a fixed plane, or there is no traction across any plane of a system of parallel planes. This theory shows that, when pressure is applied at a point of the edge of a plate in any direction in the plane of the plate, the stress developed in the plate consists exclusively of radial pressure across any circle having the point of pressure as centre, and the magnitude of this pressure is the same at all points of any circle which touches the edge at the point of pressure, and its amount at any point is inversely proportional to the radius of this circle. This result leads to a number of interesting solutions of problems relating to plate systems; among these may be mentioned the problem of a circular plate strained by any forces applied at its edge.

The results stated in § 72 have been applied to give an account of the nature of the actions concerned in the impact of two solid bodies. The dissipation of energy involved in the impact is neglected, and the resultant pressure between the bodies at any instant during the impact is equal to the rate of destruction of momentum of either along the normal to the plane of contact drawn towards the interior of the other. It has been shown that in general the bodies come into contact over a small area bounded by an ellipse, and remain in contact for a time which varies inversely as the fifth root of the initial relative velocity.

For equal spheres of the same material, with $\sigma = 1$, impinging directly with relative velocity $v$, the patches that come into contact are circles of radius

$$\sqrt{\frac{5\pi}{256}} \left( \frac{2\varepsilon}{\frac{\tau}{r}} \right)^{\frac{1}{4}} r,$$

where $r$ is the radius of either, and $V$ the velocity of longitudinal waves in a thin bar of the material. The duration of the impact is approximately

$$\sqrt{\frac{9432}{256}} \left( \frac{2025\pi}{512} \right)^{\frac{1}{6}} \frac{r}{\sqrt{\pi V \rho}}.$$

For two steel spheres of the size of the earth impinging with a velocity of 1 cm. per second the duration of the impact would be about twenty-seven hours. The fact that the duration of impact is, for moderate velocities, a considerable multiple of the time taken by a wave of compression to travel through either of two impinging bodies has been ascertained experimentally, and constitutes the reason for the adequacy of the statical theory here described.

75. Spheres and Cylinders.—Simple results can be found for spherical and cylindrical bodies strained by radial forces.

For a sphere of radius $a$, and of homogeneous isotropic material of density $\rho$, strained by the mutual gravitation of its parts, the stress at a distance $r$ from the centre consists of

1. uniform hydrostatic pressure of amount $\frac{1}{2} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,
2. radial tension of amount $\frac{1}{8} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,
3. uniform tension at right angles to the radius vector of amount $\frac{1}{4} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,

where $g$ is the value of gravity at the surface. The corresponding strains consist of

1. uniform contraction of all lines of the body of amount $\frac{1}{8} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,
2. radial extension of amount $\frac{1}{8} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,
3. extension in any direction at right angles to the radius vector of amount $\frac{1}{4} \rho a^2 g (3-\varepsilon)/(1-\varepsilon)$,

where $k$ is the modulus of compression. The volume is diminished by the fraction $\rho a^2 g k/b$ of itself. The parts of the radii vectores within the sphere $r = a(3-\varepsilon)/(3-\varepsilon)$ are contracted, and the parts without $\varepsilon$ are extended. The application of the above results to the state of the interior of the earth involves a neglect of the caution emphasized in § 40, viz. that the strain determined by the solution must be small if the solution is to be accepted. In a body of the size and mass of the earth, and having a resistance to compression and a rigidity equal to those of steel, the radial contraction at the centre, as given by the above solution, would be nearly $\varepsilon$, and the radial extension at the surface nearly $3\varepsilon$, and these fractions can by no means be regarded as "small."

76. In a spherical shell of homogeneous isotropic material, of internal radius $r_1$ and external radius $r_0$, subjected to pressure $p_0$ on the outer surface, and $p_1$ on the inner surface, the stress at any point distance $r$ from the centre consists of

1. uniform tension in all directions of amount $\frac{1}{8} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$,
2. radial pressure of amount $\frac{1}{8} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$,
3. tension in all directions at right angles to the radius vector of amount $\frac{1}{4} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$.

The corresponding strains consist of

1. uniform extension of all lines of the body of amount $\frac{1}{8} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$,
2. radial contraction of amount $\frac{1}{8} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$,
3. extension in all directions at right angles to the radius vector of amount $\frac{1}{4} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$,

where $\mu$ is the modulus of rigidity of the material, $\mu E/(1-\varepsilon)$. The volume included between the two surfaces of the body is increased by the fraction $\frac{1}{4} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$ of itself, and the volume within the inner surface is increased by the fraction

$\frac{3}{4} \rho r^2 p_0 (3-\varepsilon)/(1-\varepsilon)$

of itself. For a shell subject only to internal pressure $p$ the greatest extension is the extension at right angles to the radius at the inner surface, and its amount is

$$\frac{p r^2}{\rho r^2 - r^2 (1 + \frac{1}{4} \mu E)};$$

the greatest tension is the transverse tension at the inner surface, and its amount is

$$p (r^2 + r^2)/r^2 (1 + \frac{1}{4} \mu E)).$$

77. In the problem of a cylindrical shell under pressure a complication may arise from the effects of the ends; but when the ends are free from stress the solution is very simple. With notation similar to that in § 76 it can be shown that the stress at a distance $r$ from the axis consists of

1. uniform tension in all directions at right angles to the axis of amount $\frac{1}{8} \rho r^2 p^2 (3-\varepsilon)/(1-\varepsilon)$,
2. radial pressure of amount $\frac{1}{8} \rho r^2 p^2 (3-\varepsilon)/(1-\varepsilon)$,
3. hoop tension numerically equal to this radial pressure.
ELASTICITY

The corresponding strains consist of
(1) uniform extension of all lines of the material at right angles to the axis of amount
\[
1 - \sigma \frac{p r^2 - \rho d^2}{E r^2 - r^1 r^2 - r^1 r^2},
\]
(2) radial contraction of amount
\[
1 + \frac{\rho}{E} r^2 - r^1 r^2.
\]

(3) extension along the circular filaments numerically equal to this radial contraction,
(4) uniform contraction of the longitudinal filaments of amount
\[
\frac{6 \pi}{E} r^1 r^2 r^2.
\]

For a shell subject only to internal pressure \( p \) the greatest extension is the circumferential extension at the inner surface, and its amount is
\[
\frac{E}{(r^2 - r^1 r^2 + \varepsilon)}.
\]
The greatest tension is the hoop tension at the inner surface, and its amount is \( p(r^2 + \varepsilon) / (r^2 - r^1 r^2) \).

When the ends of the tube, instead of being free, are closed by disks, so that the tube becomes a closed cylindrical vessel, the longitudinal extension is determined by the condition that the resultant longitudinal tension in the walls balances the resultant normal pressure on either end. This condition gives the value of the extension of the longitudinal filaments as
\[
(\rho r^2 - \rho r^1) / (k(r^2 - r^1)),
\]
where \( k \) is the modulus of compression of the material. The result may be applied to the experimental determination of \( k \); by measuring the increase of length of a tube subjected to internal pressure (A. Mallock, Proc. Roy. Soc. London, iv., 1904., and C. Chree, ibid.).

The results obtained in § 77 have been applied to gun construction; we may consider that one cylinder is heated so as to slip over another upon which it shrinks by cooling, so that the two form a single body in a condition of initial stress.

We take \( P \) as the measure of the pressure between the two, and \( p \) for the pressure within the inner cylinder by which the system is afterwards strained, and denote by \( r \) the radius of the common surface. To obtain the stress at any point we supposp the system consisting of radial pressure \( \frac{P}{r^1} \) and hoop tension \( \frac{P}{r^1} \) upon a system which, for the outer cylinder, consists of radial pressure \( \frac{P}{r^2} \) and hoop tension \( \frac{P}{r^2} \), and for the inner cylinder consists of radial pressure \( \frac{P}{r^2} \) and hoop tension \( \frac{P}{r^2} \). The hoop tension at the inner surface is less than this would be for a tube of equal thickness without initial stress in the ratio
\[
1 - \frac{P}{\rho r^2} = 1.
\]
This shows how the strength of the tube is increased by the initial stress. When the initial stress is produced by tightly wound wire, a similar gain of strength accrues.

80. In the problem of determining the distribution of stress and strain in a circular cylinder, rotating about its axis, simple solutions have been obtained which are sufficiently exact for the two special cases of a thin disk and a long shaft.

Suppose that a circular disk of radius \( a \) and thickness \( 2\ell \), and of density \( \rho \), rotates about its axis with angular velocity \( \omega \), and consider the following systems of superposed stresses at any point distant \( r \) from the axis and \( z \) from the middle plane:
(1) uniform tension in all directions at right angles to the axis of amount
\[
\frac{1}{E} \sigma r^2(3 + \varepsilon).
\]
(2) radial pressure of amount \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \),
(3) pressure along the circular filaments of amount \( \frac{1}{E} \sigma r^2(1 + 3\varepsilon) \),
(4) uniform tension in all directions at right angles to the axis of amount
\[
\frac{1}{E} \sigma r^2(3 + \varepsilon).
\]
The corresponding strains may be expressed as
(1) uniform extension of all filaments at right angles to the axis of amount
\[
1 - \sigma \frac{r^2}{E} r^2(3 + \varepsilon),
\]
(2) radial contraction of amount
\[
1 + \frac{\sigma}{E} r^2,
\]
(3) contraction along the circular filaments of amount
\[
1 - \frac{\sigma}{E} r^2.
\]

(4) extension of all filaments at right angles to the axis of amount
\[
\frac{1}{E} \sigma r^2(3 + \varepsilon).
\]

(5) contraction of the filaments normal to the plane of the disk of amount
\[
\frac{1}{E} \sigma r^2(3 + \varepsilon).
\]
The greatest extension is the circumferential extension near the centre, and its amount is
\[
\frac{3 + \varepsilon}{E} r^2.
\]
The longitudinal contraction is required to make the plane faces of the disk free from pressure, and the terms in \( 1 \) and \( z \) enable us to avoid tangential tension on any cylindrical surface. The system of stresses and strains thus expressed satisfies all the conditions, except that there is a small radial tension on the bounding surface of amount per unit area \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \). The result of these tensions on any part of the edge of the disk vanishes, and the stress in question is very small in comparison with the stresses involved when the disk is thin; we may conclude that, for a thin disk, the expressions given represent the actual condition at all points which are not very close to the edge (cf. § 55).

The effect to the longitudinal contraction, that is the presence of \( z \), become slightly concave (fig. 32).

81. The corresponding solution for a disk with a circular hole (radius \( b \) will be obtained from that given in the last section by superposing the following system of additional stresses:
(1) radial tension of amount \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \),
(2) tension along the circular filaments of amount
\[
\frac{1}{E} \sigma r^2(1 + 3\varepsilon),
\]
(3) contraction of the filaments parallel to the axis of amount
\[
\frac{1}{E} \sigma r^2(1 + 3\varepsilon).
\]

The corresponding additional strains are
(1) radial contraction of amount
\[
\frac{1}{E} \sigma r^2(1 + 3\varepsilon),
\]
(2) extension along the circular filaments of amount
\[
\frac{1}{E} \sigma r^2(1 + 3\varepsilon),
\]
(3) contraction of the filaments parallel to the axis of amount
\[
\frac{1}{E} \sigma r^2(1 + 3\varepsilon).
\]

Again, the greatest extension is the circumferential extension at the inner surface, and, when the hole is very small, its amount is nearly the same as it would be for a complete disk.

82. In the problem of the rotating shaft we have the following stress-system:
(1) radial tension of amount \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \),
(2) circumferential tension of amount
\[
\frac{1}{E} \sigma r^2(3 + \varepsilon),
\]
(3) longitudinal tension of amount \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \).

The resultant longitudinal tension at each normal section vanishes, and the radial tension vanishes at the bounding surface; and thus the expressions given may be taken to represent the actual condition at all points which are not very close to the ends of the shaft. The contraction of the longitudinal filaments is uniform and equal to \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \). The greatest extension in the rotating shaft is the circumferential extension close to the axis, and its amount is \( \frac{1}{E} \sigma r^2(3 + \varepsilon) \).

The value of any theory of the strength of long rotating shafts founded on these formulæ is diminished by the circumstance that at sufficiently high speeds the shaft may tend to take up a curved form, the straight form being unstable. The shaft is then said to whirl. This occurs when the circumferential strain of rotation of the shaft is very nearly coincident with one of its periods of lateral vibration. The lowest speed at which whirlimg can take place in a shaft of length \( l \), freely supported at its ends, is given by the formula
\[
\omega = \sqrt{E \rho l / (1 - \sigma)}.
\]
As in § 61, this formula should not be applied unless the length of the shaft is a considerable multiple of its diameter. It implies that whirlimg is to be expected whenever \( \omega \) approaches this critical value.

83. When the forces acting upon a spherical or cylindrical body are not radial, the problem becomes more complicated. In the case of the sphere deformed by any forces it has been completely solved, and the solution has been applied by Lord Kelvin and
ELASTICITY

Sir G. H. Darwin to many interesting questions of cosmical physics. The nature of the stress produced in the interior of the earth by the weight of continents and mountains, the spheroidal figure of a rotating solid planet, the rigidity of the earth, are among the questions which have in this way been attacked. Darwin concluded from his investigation that, to support the weight of the existing continents and mountain ranges, the materials of which the earth is composed must, at great depths (1600 kilometres), have at least the strength of granite. Kelvin concluded from his investigation that the actual heights of the tides in the existing oceans can be accounted for only on the supposition that the interior of the earth is solid, and of rigidity nearly as great as, if not greater than, that of steel.

83. The general problem of vibrations of solids is to determine the stresses produced in a cylinder of finite length by forces distributed symmetrically round the axis have been solved. The most important is that of a cylinder crushed between parallel planes in contact with its plane ends. The solution was applied to explain the discrepancies that have been observed in different tests of crushing strength according as the ends of the test specimen are or are not prevented from spreading. It was applied also to explain the fact that in such tests small conical pieces are sometimes cut out at the ends subjected to pressure.

83. Vibrations and Waves.—When a solid body is struck, or otherwise suddenly disturbed, it is thrown into a state of vibration. There always exist dissipative forces which tend to destroy the vibratory motion, one cause of the subsidence of the motion being the communication of energy to surrounding bodies. When these dissipative forces are disregarded, it is found that an elastic solid body is capable of vibrating in such a way that the motion of any particle is simple harmonic motion, all the particles completing their oscillations in the same period and being at any instant in the same phase, and the displacement of any selected one in any particular direction bearing a definite ratio to the displacement of an assigned one in an assigned direction. When a body is moving in this way it is said to be vibrating in a normal mode. For example, when a tightly stretched string of negligible flexural rigidity, such as a violin string, may be taken to be, is fixed at the ends, and vibrations transversely in a normal mode, the displacements of all the particles have the same direction, and their magnitudes are proportional at any instant to the ordinates of a curve of sines. Every body possesses an infinite number of normal modes of vibration, and the frequencies (or numbers of vibrations per second) that belong to the different modes form a sequence of increasing numbers. For the string, above referred to, the fundamental tone and the various overtones form an harmonic scale, that is to say, the frequencies of the normal modes of vibration are proportional to the integers 1, 2, 3, ... In all these modes except the first the string vibrates as if it were divided into a number of equal pieces, each having fixed ends; this number is in each case the integer defining the frequency. In general the normal modes of vibration of a body are distinguished one from another by the number and situation of the surfaces (or other loci) at which some characteristic displacement or traction vanishes. The problem of determining the normal modes and frequencies of free vibration of a body of definite size, shape and constitution, is a mathematical problem of a similar character to the problem of determining the state of stress in the body when subjected to given forces. The bodies which have been studied are rings and thin bodies, branes, thin plates and shells, including bells, spheres and cylinders. Most of the results are of special importance in their bearing upon the theory of sound.

86. The most complete success has attended the efforts of mathematicians to solve the problem of free vibrations for an isotropic sphere. The method reduces normal modes of vibration to those that are characterized by the absence of a radial component of displacement, and the other by the absence of a radial component of rotation (§ 14). In each class there is a doubly infinite number of modes. The displacement in any mode is determined in terms of a single spherical harmonic function, so that there are modes of each class corresponding to spherical harmonics of every integral degree, and there is an infinite number of modes from one another in the number and position of the concentric spherical surfaces at which some characteristic displacement vanishes. The most interesting modes are those in which the sphere becomes slightly spheroidal, being alternately prolate and oblate during the course of a vibration; these vibrations tend to be set up in a spherical planet by tide-generating forces. In a sphere of the size of the earth, supposed to be incompressible and as rigid as steel, the period of these vibrations is 66 minutes.

87. The theory of free vibrations has an important bearing upon the question of the strength of structures subjected to sudden blows or shocks. The stress and strain developed in a body by sudden applications of force may exceed considerably those which would be produced by a gradual application of the same forces. Hence there arises the general question of dynamical resistance, or of the resistance of a body to forces applied so quickly that the inertia of the body comes sensibly into play. In regard to this question we have two chief theoretical results. The first is that the strain produced by a force suddenly applied may be as much as twice the statical strain, that is to say, as the strain which would be produced by the same force when the body is held in equilibrium under its action; the second is that the sudden reversal of the force may produce a strain three times as great as the statical strain. These results point to the importance of specially strengthening the parts of any machine (e.g. screw propeller shafts) which are subject to sudden application of force. The reversals of the stress in structural members, though up to three times, the statical strain are not in general attained. For example, if a thin bar hanging vertically from its upper end is suddenly loaded at its lower end with a weight equal to its own weight, the greatest dynamical strain bears to the greatest statical strain the ratio 1:63:1; when the attached weight is four times the weight of the bar the ratio becomes 1:84:1. The method by which the result just mentioned is reached has recently been applied to the question of the breaking of winding ropes used in mines. It appeared that, in order to bring the results into harmony with the observed facts, the strain in the supports must be taken into account as well as the strain in the rope (J. Perry, Phil. Mag., 1906 (vi.), vol. ii.).

88. The immediate effect of a blow or shock, locally applied to a body, is the generation of a wave which travels through the body from the locality first affected. The question of the propagation of waves through an elastic solid body is historically of very great importance; for the first really successful efforts to construct a theory of elasticity (those of S. D. Poisson, A. L. Cauchy and G. Green) were prompted, at least in part, by Fresnel's theory of the propagation of light by transverse vibrations. For many years the luminiferous medium was identified with the isotropic solid of the theory of elasticity. Poisson showed that a disturbance communicated to the body gives rise to two waves which are propagated through it with different velocities; G. St. L. B. M. G. Stoney showed that the quicker wave is a wave of irrotational dilatation, and the slower wave is a wave of rotational distortion accompanied by no change of volume. The velocities of the two waves in a solid of density \( \rho \) are \( \sqrt{(\lambda + 2\mu)/\rho} \) and \( \sqrt{\mu/\rho} \), \( \lambda \) and \( \mu \) being the constants so denoted in § 26. When the surface of the body is free from traction, the waves on reaching the surface are reflected; and thus after a little time the body would, if there were no dissipative forces, be in a very complex state of motion due to multitudes of waves passing into and from through it. This state can be expressed as a state of vibration, in which the motions belonging to the various normal modes (§ 85) are superposed, each with an appropriate amplitude and phase. The waves of dilatation and distortion do not, however, give rise to different modes of vibration, as was at one time supposed, but any mode of vibration in general involves both dilatation and rotation. There are exceptional results for solids of revolution; such solids possess normal modes of vibration which involve no dilatation. The existence of a boundary to the solid body has another effect, besides reflection, upon the propagation of waves. Lord Rayleigh has shown that any disturbance originating at the surface gives rise to waves which travel away over the surface as well as to waves which travel through the interior; and any internal disturbance, on reaching the surface, also gives rise to such superficial waves. The velocity of the superficial waves is a little less than that of the waves of distortion:
ELASTICITY 159

\[ 0.9554 \sqrt{\mu/p} \]

when the material is incompressible \( 0.9104 \sqrt{\mu/p} \)

when the Poisson’s ratio belonging to the material is \( 1 / 3 \).

These results have an application to the propagation of earthquake tremors (see also Earthquake). An internal disturbance should, if the earth can be regarded as solid, give rise to three wave-motions: two propagated through the interior of the earth with different velocities, and a third propagated over the surface. The results of seismographic observations have independently led to the recognition of three phases of the recorded vibrations: a set of “preliminary tremors” which are received at different stations at such times as to show that they are transmitted directly through the interior of the earth with a velocity of about 10 km. per second, a second set of preliminary tremors which are received at different stations at such times as to show that they are transmitted directly through the earth with a velocity of about 5 km. per second, and a “main shock,” or set of large vibrations, which becomes sensible at different stations at such times as to show that a wave is transmitted over the surface of the earth with a velocity of about 3 km. per second. These results can be interpreted if we assume that the earth is a solid body the greater part of which is practically homogeneous, with high values for the rigidity and the resistance to compression, while the superficial portions have lower values for these quantities. The rigidity of the central portion would be about \( (4.4) \times 10^{18} \) dyynes per square cm., which is considerably greater than that of steel, and the resistance to compression would be about \( (3.8) \times 10^{15} \) dyynes per square cm. which is much greater than that of any known material. The rapidity of the wave is not surprising when account is taken of the great pressures, due to gravitation, which must exist in the interior of the earth. The high value of the rigidity can be regarded as a confirmation of Lord Kelvin’s estimate founded on tidal observations (§ 83).

90. Strain produced by Heat.—The mathematical theory of elasticity as at present developed takes no account of the strain which is produced in a body by unequal heating. It appears to be impossible in the present state of knowledge to form as in § 39 a system of differential equations to determine both the stress and the temperature at any point of a solid body the temperature of which is liable to variation. In the cases of isothermal and adiabatic changes, that is to say, when the body is slowly strained without variation of temperature, and also when the changes are effected so rapidly that there is no gain or loss of heat by any element, the internal energy of the body and the stress represented by the equations (§§ 37, 30). Thus states of equilibrium and of rapid vibration can be determined by the theory that has been explained above. In regard to thermal effects we can obtain some indications from general thermodynamic theory. The following passages extracted from the article “Elasticity” contributed to the 9th edition of the Encyclopaedia Britannica by Sir W. Thomson (Lord Kelvin) illustrate the nature of these indications:

“From thermodynamic theory it is concluded that cold is produced whenever a solid is strained by opposing, and heat when it is strained by yielding to, any elastic force of its own, the strength of which would diminish if the temperature were raised; but that, on the contrary, heat is produced when a solid is strained against, and cold when it is strained by yielding to, any elastic force of its own, the strength of which would increase if the temperature were raised. When the strain is a condensation or dilatation, uniform in all directions, a fluid may be included in the statement. Heat is produced by compression, but it is not necessary to extremities; for instance, a sheet of metal rolled into a cylinder, and soldered to maintain the tubular shape, must be in a state of considerable initial stress quite apart from the action of gravity. Initial stress is utilized in many manufacturing processes, as, for example, in the construction of ordnance, referred to in § 79, in the winding of golf balls by means of India-rubber in a state of high tension (see the report of the case The Haskell Golf Ball Company v. Hutchinson & Main in The Times of March 1, 1906). In the case of a body of ordinary dimensions it is such internal stress
ELATERITE—ELBA

ELATERITE, also termed Elastic Bitumen and Mineral Cautchouc, a mineral hydrocarbon, which occurs at Castleton in Derbyshire, in the lead mines of Odin and elsewhere. It becomes somewhat inelastic, and sometimes brittle; it is elastic and sticky; often closely resembling india-rubber; and occasionally hard and brittle. It is usually dark brown in colour and slightly translucent. A substance of similar physical character is found in the Coorong district of South Australia, and is hence termed coorongite, but Prof. Ralph Tate considers this to be a vegetable product.

ELATERIUM, a drug consisting of a sediment deposited by the juice of the fruit of Eclatium Elaterium, the squiring cucumber, a native of the Mediterranean region. The plant, which is a member of the natural order Cucurbitaceae, resembles the vegetable marrow in its growth. The fruit resembles a small cucumber, and when ripe is highly turgid, and separates almost at a touch from the fruit stalk. The end of the stalk forms a stopper, on the removal of which the fluid contents of the fruit, together with the seeds, are squirted through the aperture by the sudden contraction of the wall of the fruit. To prepare the drug the fruit is sliced lengthwise and slightly pressed; the greenish and slightly turbid juice thus obtained is strained and set aside; and the deposit of elaterium formed after a few hours is collected on a linen filter, rapidly drained, and dried on porous tiles at a gentle heat. Elaterium is met with in commerce in light, thin, friable, flat or slightly incurved opaque cakes, of a greyish-green colour, bitter taste and tea-like smell.

The drug is soluble in alcohol, but insoluble in water and ether. The official dose is 1/4-1/2 grain, and the British pharmacopoeia directs that the drug is to contain from 20 to 25% of the active principle elaterium or elaterin. A resin in the natural product aids its action. Elaterin is extracted from elaterium by chloroform and then precipitated by ether. It has the formula C₇₆H₄₈O₁₈. It forms colourless scales which have a bitter taste, but it is highly inadvisable to taste either this substance or elaterium. Its dose is 1-2 grains, and the British pharmacopoeia contains a useful preparation, the Pulvis Elaterini Compositus, which contains one part of the active principle in forty.

The action of this drug resembles that of the saline aperients, but is much more powerful. It is the most active hydrogogoue purgative known, causing also much depression and violent griping. When injected subcutaneously it is inert, as its action is entirely dependent upon its admixture with the bile. The drug is undoubtedly valuable in cases of dropsy and Bright’s disease, and also in cases of cerebral haemorrhage, threatened or present. It must not be used except in urgent cases, and must invariably be employed with the utmost care, especially if the state of the heart be unsatisfactory.

ELBA (Gr. Ἐλβα; Lat. Itea), an island off the W. coast of Italy, belonging to the province of Leporno, from which it is 45 m. S., and 7 m. S.W. of Piumbino, the nearest point of the mainland. Pop. (1901) 25,043 (including Pianosa). It is about 19 m. long, 63 m. broad, and 140 sq. m. in area; and its highest point is 3,340 ft. (Monte Capanne). It forms, like Giglio and Monte Cristo, part of a sunken mountain range extending towards Corsica and Sardinia.

The oldest rocks of Elba consist of schist and serpentine which in the eastern part of the island are overlaid by beds containing Silurian and Devonian fossils. The Permian may be represented, but the Trias is absent, and in general the older Palaeozoic rocks are overlaid directly by the Rhetic and Lias. The Liassic beds are often metamorphosed and the limestones contain garnet and wollastonite. The next geological formation which is represented is the Eocene, consisting of nummulitic limestone, sandstone and schist. The Miocene and Pliocene are absent. The most remarkable feature in the geology of Elba is the extent of the granitic and ophiolitic eruptions of the Tertiary period. Serpentine, peridotites and diabases are interstratified with the deposits. The granite, which is intruded through the Eocene beds, is associated with a pegmatite containing tourmaline and cassiterite. The celebrated iron ore of Elba is of
ELBE

Tertiary age and occurs indifferently in all the older rocks. The deposits are superficial, resulting from the opening out of veins at the surface, and consist chiefly of haematite. These ores were worked by the ancients, but so inefficiently that their spoilheaps can be smelted again with profit. This process is now gone through on the island itself. The granite was also quarried by the ancients, but not now worked, the fourth.

Parts of the island are fertile, and the cultivation of vines, and the sunny and sardine fishery, also give employment to a part of the population. The capital of the island is Porto Ferraio—pop. (1901) 3987—in the centre of the N. coast, enclosed by an amphitheatre of lofty mountains, the slopes of which are covered with villas and gardens. This is the best harbour, the ancient Portus Argus. The town was built and fortified by Cosimo I. in 1548, who called it Cosmopolis. Above the harbour, between the forts Stella and Falcone, is the palace of Napoleon I., and 4 m. to the S.W. is his villa; while on the N. slope of Monte Capanne is another of his country houses. The other villages in the island are Campo nell' Elba, on the S. near the W. end, Marciana and Marciana Marina on the N. of the island near the W. extremity, Porto Longone, on the E. coast, with picturesque Spanish fortifications, constructed in 1602 by Philip III.; Rio dell' Elba and Rio Marina, both on the W. side of the island in the mining district. At Le Grotte, between Porto Ferraio and Rio dell' Elba, and at Capo Castello, on the N.E. of the island, are ruins of Roman date.

Elba was famous in early times, and the smelting furnaces gave it its Greek name of Α'θηλια ("soul island"). In Roman times, and until 1900, however, owing to lack of fuel, the smelting was done on the mainland. In 453 A.C. Elba was devastated by a Syracusan squadron. From the 11th to the 14th century it belonged to Pisa, and in 1399 came under the dukes of Fiombino. In 1548 it was ceded by them to Cosimo I. of Florence. In 1596 Porto Longone was taken by Philip III. of Spain, and retained until 1700, when it was ceded to Naples. In 1802 the island was given to France by the peace of Amiens. On Napoleon's deposition, the island was ceded to him with full sovereign rights, and he resided there from the 5th of May 1814 to the 26th of February 1815. After his fall it was restored to Tuscany, and passed with it to Italy in 1860.

See Sir R. Colt Hoare, A Tour through the Island of Elba (London, 1814).

ELBE (the Albis of the Romans and the Labe of the Czechs), a river of Germany, which rises in Bohemia not far from the frontiers of Silesia, on the southern side of the Riesengebirge, at an altitude of about 4000 ft. Of the numerous small streams (Seifen or Fiessen as they are named in the district) whose confluent waters compose the infant river, the most important are the Waal, the White Waal, and the Elbe, which is formed in the same neighbourhood, but at a little lower elevation. After plunging down the 140 ft. of the Elbefall, the latter stream unites with the steep torrential Weisswasser at Mädelstegbaude, at an altitude of 2920 ft., and thereafter the united stream of the Elbe pursues a southerly course, emerging from the mountain glens at Hohenelbe (1495 ft.), and continuing on to a soberer pace to Pardubitz, where it turns sharply to the west, and at Kolín (910 ft.), some 167 m. farther on, bends gradually towards the north-west. A little above 'Branděe it picks up the Isar, which, like itself, comes down from the Riesengebirge, and at Melnik it has its stream more than doubled in volume by the Moldau, a river which winds northwards through the heart of Bohemia in a sinuous, trough-like channel carved through the plateaux. Some miles lower down, at Leitmeritz (433 ft.), the waters of the Elbe are tinted by the reddish Eger, a stream which drains the Bohemian area, but the_Eger has now disappeared. Thus swollen into a stream 140 yds. wide, the Elbe carves a path through the basaltic mass of the Mittelgebirge, charming its way through a deep, narrow rocky gorge. Then the river winds through the fantastically sculptured sandstone mountains of the "Saxon Switzerland," washing successively the feet of the lofty Lilienstein (932 ft. above the Elbe), the scene of one of Frederick the Great's military exploits in the Seven Years' War, Königstein (997 ft. above the Elbe), where in times of war Saxony has more than once stored her national purse for security, and the pinnacled rocky wall of the Bastei, towering 650 ft. above the surface of the stream. Shortly after crossing the Bohemian-Saxon frontier, and whilst still struggling through the sandstone defiles, the stream assumes a north-westerly direction, which on the whole it keeps, except for the short stretch right away from the Elbe to the North Sea, as it is carried by the leaves behind it the stress and turmoil of the Saxon Switzerland, rolls through Dresden, with its noble river terraces, and finally, beyond Meißen, enters on its long journey across the North German plain, touching Torgau, Wittenberg, Magdeburg, Wittenberge, Hamburg, Harburg and Altona on the way, and gathering into itself the waters of the Mulde and Saale from the left, and those of the Schwarze Elster, Havel and Elde from the right. Eight miles above Hamburg the stream divides into the Norder (or Hamburg) Elbe and the Süder (or Harburg) Elbe, which are linked together by several cross-channels, and embrace in their arms the large island of Wilhelmsburg and some smaller ones. But by the time the river reaches Blankenese, 7 m. below Hamburg, all these anastomosing branches have been reunited, and the Elbe, with a width of 4 to 9 m. between bank and bank, travels on between the green marshes of Holstein and Hanover until it becomes merged in the North Sea off Cuxhaven. At Kolín, the width is about 1000 ft., at the mouth of the Moldau about 900, at Dresden 960, and at Magdeburg over 1000. From Dresden to the sea the river has a total fall of only 280 ft., although the distance is about 430 m. For the 75 m. between Hamburg and the sea the fall is only 3 ft. One consequence of this is that the bed of the river just below Hamburg is obstructed by a bar, and still lower down is choked with sandbanks, so that navigation is confined to a relatively narrow channel down the middle of the river. But unremitting efforts have been made to maintain a sufficient fairway up to Hamburg (g.s.). The tide advances as far as Geesthacht, a little more than 100 m. from the sea. The river is navigable as far as Melnik, that is, the confluence of the Moldau, a distance of 525 m., of which 67 are in Bohemia. It total length is 725 m., of which 190 are in Bohemia, 77 in the kingdom of Saxony, and 350 in Prussia, the remaining 108 being in Hamburg and other states of Germany. The area of the drainage basin is estimated at 36,000 sq. m.

Navigation.—Since 1842, but especially since 1871, improvements have been made in the navigability of the Elbe by all the states which border upon its banks. As a result of these labours there is now in the Bohemian portion of the river a minimum depth of 2 ft. 8 in., whilst from the Bohemian frontier down to Magdeburg the minimum depth is 3 ft., and from Magdeburg to Hamburg 3 ft. 20 in. In 1866 and 1871 Prussia and Hamburg signed covenants whereby two channels are to be kept open to a depth of 9 ft., a width of 656 ft., and a length of 520 yds. between Buxhaus and Ortkathen, just above the bifurcation of the Norder Elbe and the Süder Elbe. In 1860 the maximum burden of the vessels which were able to ply on the upper Elbe was 250 tons; but in 1895 it was increased to 800 tons. The large towns through which the river flows have vied with one another in building harbours, providing shipping accommodation, and furnishing other facilities for the efficient navigation of the Elbe. In this respect the greatest efforts have naturally been made by Hamburg; but Magdeburg, Dresden, Meißen, Riesa, Tetschen, Aussig and other places have all done their relative shares, Magdeburg, for instance, providing a commercial harbour and a winter harbour. In spite, however, of all that has been done, the Elbe remains subject to serious inundations at periodic intervals. Among the worst floods were those of the years 1774, 1799, 1815, 1820, 1845, 1862, 1870 and 1900. The present river has, however, much less water than that which used to flow through the city of Dresden, and the Elbe is no longer very considerable. A towing channel, laid in the bed of the river, extends from Hamburg to Aussig, and by this means, as by paddle-tug haulage, large barges are brought from the port of Hamburg into the heart of Bohemia. The fleet of steamers and barges navigating the Elbe is in point of fact greater than on any other German river. In addition to goods thus conveyed, enormous quantities of timber are floated down the Elbe; the
weight of the rafts passing the station of Schandau on the Saxon Bohemian frontier amounting in 1901 to 333,000 tons.

A vast amount of traffic is directed to Berlin, by means of the Havel-Spree system of canals, to the Thuringian states and the Prussian province of Saxony, to the kingdom of Saxony and Bohemia, and to the various riverine states and provinces of the lower and middle Elbe. The passenger traffic, which is in the hands of the Sächsische-Böhmische Dampfschiffahrts-gesellschaft, is limited to Bohemia and Saxony, steamers plying up and down the stream from Dresden to Melnik, occasionally continuing the journey up the Moldau to Prague, and down the river as far as Riesa, near the northern frontier of Saxony, and on the average 11 million passengers are conveyed.

In 1877-1879, and again in 1888-1895, some 100 m. of canal were dug, 5 to 6 ft. deep and of various widths, for the purpose of connecting the Elbe, through the Havel and the Spree, with the system of the Oder. The most noteworthy of these connexions are the Elbe Canal (142 m. long), the Reck Canal (99 m.), the Rüdersdorfer Gewässer (114 m.), the Rheinsberger Canal (112 m.), and the Sacrow-Paretzer Canal (10 m.), besides which the Spree has been canalized for a distance of 28 m., and the Elbe for a distance of 70 m. Since 1856 great improvements have been made in the Moldau and the Bohemian Elbe, with the view of facilitating communication between Prague and the middle of Bohemia generally on the one hand, and the middle and lower reaches of the Elbe on the other. In the year named a special commission was appointed for the regulation of the Moldau and Elbe between Prague and Aussig, at a cost estimated at about £1,000,000, of which sum two-thirds were to be borne by the Austrian empire and one-third by the kingdom of Bohemia. The regulation is effected by locks and movable dams, the latter so designed that in times of flood or frost they can be dropped flat on the bottom of the river. In 1900 the Austrian government laid before the Reichsrat a canal bill, with proposals for works estimated to take twenty years to complete, and including the construction of a canal between the Oder, starting at Gradau, and the upper Elbe at Pardubitz, and for the canalization of the Elbe from Pardubitz to Melnik (see AUSTRIA: Waterways). In 1900 Lübeck was put into direct communication with the Elbe at Lauenburg by the opening of the Elbe-Trave Canal, 42 m. in length, and constructed at a cost of £1,177,700, of which the state of Lübeck contributed £820,700, and the kingdom of Prussia £375,000. The canal has been made 72 ft. wide at the bottom, 105 to 126 ft. wide at the top, has a minimum depth of 8 ft., and is equipped with seven locks, each 262 ft. long and 39 ft. wide. It is thus able to accommodate vessels up to 600 tons burden, and the passage from Lübeck to Lauenburg occupies 12 to 24 hours, a third of the time of its being opened in 1901. A total of 112,000 tons passed through the canal. A gigantic project has also been put forward for providing water communication between the Rhine and the Elbe, and so with the Oder, through the heart of Germany. This scheme is known as the Midland Canal. Another canal has been projected for connecting Kiel with the Elbe by means of a canal trained through the Flotte Lakes.

Bridges.—The Elbe is crossed by numerous bridges, as at Königgrätz, Pardubitz, Kolín, Letatitz, Tetschen, Schandau, Pirna, Dresden, Meissen, Torgau, Wittenberg, Rossau, Barby, Magdeburg, Rathenow, Wittenberg, Dömitz, Lauenburg, and Hamburg and Harburg. At all these places there are railway bridges, and nearly all, but more especially those in Bohemia, Saxony and the middle course of the river—these last on the main lines between Berlin and the west and south-west of the empire—possess a greater or less strategic value. At Letatitz there is an iron trellis bridge, 600 yds. long. Dresden has four bridges, and there is a fifth bridge at Loschwitz, about 3 m. above the city. Meissen has a railway bridge, in addition to an old road bridge. Magdeburg is one of the most important railway centres in northern Germany; and the Elbe, besides being bridged—it divides there into three arms—several times for vehicular traffic.

ELBE is also spanned by two fine railway bridges. At both Hamburg and Harburg, again, there are handsome railway bridges, the one (1868-1873 and 1894) crossing the northern Elbe, and the other (1900) the southern Elbe; and the former arm is also crossed by a fine triple-arched bridge (1888) for vehicular traffic.

The river is rich with both salt-water and fresh-water species being found in its waters, and several varieties of fresh-water fish in its tributaries. The kinds of greatest economic value are sturgeon, shad, salmon, lampreys, eels, pike and whiting.

Tolls.—In the days of the old German empire no fewer than thirty-five different tolls were levied between Melnik and Hamburg, to say nothing of the special dues and privileged exactions of various riparian owners and political authorities. After these had been de facto, though not de jure, in abeyance during the period of the Napoleonic wars, a commission of the various Elbe states met and drew up a scheme for their regulation, and the scheme, embodied in the Elbe Navigation Acts, came into force in 1822. By this a definite number of tolls, at fixed rates, was substituted for the often arbitrary tolls which had been exacted previously. Still further relief was afforded in 1844 and in 1850, on the latter occasion by the abolition of all tolls between Melnik and the Rhin; but the number of tolls was only reduced to one, levied at Wittenberge, in 1863, about one year after Hanover was induced to give up the Stade or Brunsbüttel toll in return for a compensation of 2,575,340 thalers. Finally, in 1870, 1,000,000 thalers were paid to Mecklenburg and 85,000 thalers to Anhal, which thereupon abandoned all claims to levy tolls upon the Elbe shipping, and thus navigation on the river became at last entirely free.

History.—The Elbe cannot rival the Rhine in the picturesqueness of the scenery it travels through, nor in the glamour which its romantic and legendary associations exercise over the imagination. But it possesses much to charm the eye in the deep glens of the Riesengebirge, amid which its sources spring, and in the bizarre rock-carving of the Saxon Switzerland. It has been indirectly or directly associated with many stirring events in the history of the German peoples. In its lower course, whatever is worthy of record clusters round the historical vicissitudes of Hamburg—it is early prominence as a missionary centre (Ansgar) and as a bulwark against Slav and marauding Northman, its commercial prosperity as a leading member of the Hanseatic League, and its sufferings during the Napoleonic wars, especially at the hands of the ruthless Davout. The bridge over the river at Dessau recalls the hot assaults of the condottiere Ernst von Mansfeld in April 1626, and his repulse by the crafty generalship of Wallenstein. But three years later this imperious leader was captured on the field of Nurnberg (June 1638), and brought to the fortress of Magdeburg; though two years later still she lost her reputation, and suffered unspeakable horrors at the hands of Tilly's lawless and unlicensed soldiery. Mittelburg, just outside the Saxony frontier, is the place where Charles V. asserted his imperial authority over the Protestant elector of Saxony, John Frederick, the Magnanimous or Unfortunate, in 1547. Dresden, Aussig and Leitmeritz are all reminiscent of the fierce battles of the Hussite wars, and the last named of the Thirty Years' War. But the chief historical associations of the upper (i.e. the Saxon and Bohemian) Elbe are those which belong to the Seven Years' War, and the struggle of the great Frederick of Prussia against the power of Austria and her allies. At Pirna (and Lilienstein) in 1756 he caught the entire Saxon army in his follower's net, after driving back at Lobositz the Austrian forces which were hastening to their assistance; but only nine months later he lost his reputation for "indefatigability" by his crushing defeat at Kolín, where the great highway from Vienna is crossed by the Elbe. Not many miles distant, higher up the stream, another decisive battle was fought between the same national antagonists, but with a contrary result, on the memorable 3rd of July 1866.

ELBERFELD—ELBING

Reichs." in Geog. Zeitschrift (1898), pp. 601-617; and (the official) Der Elbtrom (1900); B. Weissenborn, Die Elbtönelle und Elbstoepel-
gplätze im Mittelalter (Halle, 1900); Daniel, Deutschland; and A. Supan, Wasserstrassen und Binnenschifffahrt (Berlin, 1902).

ELBERFELD, a manufacturing town of Germany, in the Prussian Rhine province, on the Wupper, and immediately west of and contiguous to Barmen (q.v.). Pop. (1816) 21,710; (1840) 31,514; (1852) 109,218; (1895) 167,382. Elberfeld-Barmen, although administratively separate, practically form a single whole. It winds, a continuous strip of houses and factories, for 9 m. along the deep valley, on both banks of the Wupper, which is crossed by numerous bridges, the embankings of the river crowned with woods. Local intercommunication is provided by bus, tram, horse and line and facing the Langen mono-rail system—suspended over the bed of the river, with frequent stations. In the centre of the town are a number of irregular and narrow streets, and the river, polluted by the refuse of dye-works and factories, constitutes a constant eyesore. Yet within recent years great alterations have been effected; in the newer quarters are several handsome streets and public buildings; in the centre many insanitary dwellings have been swept away, and their place occupied by imposing blocks of shops and business premises, and a magnificent new town-hall, erected in a dominant position. Among the most recent improvements must be mentioned the Brausenwerther Platz, flanked by the theatre, the public baths, and the railway station and administrative offices. There are eleven Evangelical and five Roman Catholic churches (noticeable among the latter the Sühbettskirche), a synagogue, and chapels of various other sects. Among other public buildings may be enumerated the civic hall, the law courts and the old town-hall.

The town is particularly rich in educational, industrial, philanthropic and religious institutions. The schools include the Gymnasium (founded in 1592 by the Protestant community as a Latin school), the Realgymnasium (founded in 1830, for "modern" subjects and Latin), the Oberrealschule and Realschule (founded 1853, the latter wholly "modern"), two girls' high schools, a girls' middle-class school, a large number of popular schools, a mechanics' and polytechnic school, a school of mechanics, an industrial drawing school, a commercial school, and a school for the deaf and dumb. There are also a theatre, an institute of music, a library, a museum, a zoological garden, and numerous scientific societies. The town is the seat of the Berg Bible Society. The majority of the inhabitants are Protestant, with a strong tendency towards Pietism; but the Roman Catholics number upwards of 40,000, forming about one-fifth of the total population. The factories and workshops are on a scale of great magnitude. It is the chief centre in Germany of the cotton, wool, silk and velvet manufactures, and of upholstery, drapery and haberdashery of all descriptions, of printed calicoes, of Turkey-red and other dyes, and of fine chemicals. Leather and rubber goods, gold, silver and aluminium wares, machinery, wall-paper, and stained glass are also among other of its staple products. Commerce is lively and the exports to foreign countries are very considerable. The railway system is well devised to meet the requirements of its rapidly increasing trade. Two main lines of railway traverse the valley; that on the south is the main line from Aix-la-Chapelle, Cologne and Düsseldorf to central Germany and Berlin, that on the north feeds the important towns of the Ruhr valley.

The surroundings of Elberfeld are attractive, and public grounds and walks have been recently opened on the hills around with results eminently beneficial to the health of the population.

In the 17th century the site of Elberfeld was occupied by the castle of the lords of Elberfeld, feudatories of the archbishops of Cologne. The fief passed later into the possession of the counts of Berg. The industrial development of the place started with a colony of bleachers, attracted by the clear waters of the Wupper, who in 1532 were granted the exclusive privilege of bleaching yarn. It was not, however, until 1610 that Elberfeld was raised to the status of a town, and in 1649 was surrounded with walls. In 1760 the manufacture of silk was introduced, and dyeing with Turkey-red in 1780; but it was not till the end of the century that its industries developed into importance under the influence of Napoleon's continental system, which barred out British competition. In 1815 Elberfeld was assigned by the congress of Vienna, with the grand-duchy of Berg, to Prussia, and its prosperity rapidly developed under the Prussian Zollverein.

ELBING, a town of northern France in the department of Seine-Inferieure, 14 m. S.S.W. of Rouen by the western railway. Pop. (1866) 27,800. Elbeuf, a town of wide, clean streets, with low houses and factories, stands on the higher ground in the Seine at the foot of hills over which extends the forest of Elbeuf. A tribunal and chamber of commerce, a board of trade-arbitrators, a lycée, a branch of the Bank of France, a school of industry, a school of cloth manufacture and a museum of natural history are among its institutions. The churches of St. Étienne and St. Jean, both of the Renaissance period with later additions, preserve stained glass of the 16th century. The hôtel-de-ville and the cercle du Commerce are the chief modern buildings. The town with its suburbs, Orival, Caudebec-lès-Elbeuf, St. Aubin and St. Pierre, is one of the principal and most ancient seats of the woolen manufacture in France; more than half the inhabitants are directly maintained by the staple industry and numbers more by the auxiliary crafts. As a river-port it has a brisk trade in the produce of the surrounding district as well as in the raw materials of its manufactures, especially in wool from La Plata, Australia and Germany. Two bridges, one of them a suspension bridge, communicate with St. Aubin on the opposite bank of the Seine, and steamboats ply regularly to Rouen.

Elbeuf was, in the 13th century, the centre of an important fief held by the house of Harcourt, but its previous history goes back at least to the early years of the Norman occupation, when it appears under the name of Hollebo. It passed into the hands of the houses of Rieux and Lorraine, and was raised to the rank of a duchy in the peerage of France by Henry III. in favour of Charles of Lorraine (d. 1603), grandson of Claude, duke of Guise, master of the hounds and master of the horse of France. The last duke of Elbeuf was Charles Eugène of Lorraine, prince de Lambesc, who distinguished himself in 1789 by his energy in repressing risings of the people at Paris. He fought in the army of the Bourbons, and later in the service of Austria, and died in 1825.

ELBING, a seaport town of Germany, in the kingdom of Prussia, 40 m. by rail E.S.R. of Danzig, on the Elbing, a small river which flows into the Frische Haff about 5 m. from the town, and is united with the Nagat or eastern arm of the Vistula by means of the Kraftschof canal. Pop. (1905) 25,527. By the Elbing-Oberländischer canal, 110 m. long, constructed in 1845-1860, Lakes Gescher and Drewnow are connected with Lake Drausen, and consequently with the port of Elbing. The old town was formerly surrounded by fortifications, but of these only a few fragments remain. There are several churches, among them the Marienkirche (dating from the 13th century and restored in 1887), a classical school (Gymnasium) founded in 1506, a modern school (Realschule), a public library of over 28,000 volumes, and several charitable institutions. The town-hall (1894) contains a historical museum.

Elbing is a place of rapidly growing industries. At the great Schichau iron-works, which employ thousands of workmen, are built the best of the torpedo-boats and destroyers for the German navy, as well as larger craft, locomotives and machinery. In addition to this there are at Elbing important iron foundries, and manufactories of machinery, cigars, lacquer and metal ware, flax and hemp yarn, cotton, linen, organ, &c. There is a considerable trade also in agricultural produce.

The origin of Elbing was a colony of traders from Lübeck and Bremen, which established itself under the protection of a castle of the Teutonic Knights, built in 1237. In 1246 the town acquired "Lübeck rights," i.e. the full autonomy conceded by the charter
of the emperor Frederick II. in 1226 (see Lübeck), and it was early admitted to the Hanseatic League. In 1454 the town repudiated the lordship of the Teutonic Order, and placed itself under the protection of the king of Poland, becoming the seat of a Polish voivode. From this event dates a decline in its prosperity, a decline hastened by the wars of the early 18th century. In 1708, and again in 1709, it was seized by the elector of Brandenburg as security for a debt due to him by the Polish king. It was taken and held to ransom by Charles XII. of Sweden, and in 1710 was captured by the Russians. In 1772, when it fell to Prussia through the first partition of Poland, it was utterly decayed.

See Fuchs, Gesch. der Stadt Elbing (Elbing, 1818-1822); Rhode, Die Stadte in topographischer, historischer, und statistischer Hinsicht (Danzig, 1871); Wernick, Elbing (Elbing, 1888).

ELBOW, in anatomy, the articulation of the humerus, the bone of the upper arm, and the ulna and radius, the bones of the forearm (see JOINTS). The word is thus applied to things which are like this joint in shape, such as a sharp bend of a stream or river, an angle in a tube, &c. The word is derived from the O. Eng. elbege, a combination of ën, the forearm, and bega, a bow or bend. This combination is common to many Teutonic languages, e.g. Ger. Elbogen. Èn still survives in the name of a linear measure in Egypt, and is derivable from the O. Irish *elann*, cognate with Lat. ëна and Gr. ἕλκη, the forearm. The use of the arm as a measure of length is illustrated by the uses of ulna, in Latin, cubit, and fathom.

ELBURZ, or Alborz (from O. Pers. Hara-bere-salti, the "High Mountain"), a great chain of mountains in northern Persia, separating the Caspian depression from the Persian highlands, and extending without any break for 650 m. from the western shore of the Caspian Sea to north-eastern Khorasan. According to the direction, or strike, of its principal ranges the Elburz may be divided into three sections: the first 120 m. in length with a direction nearly N. to S., the second 240 m. in length with a direction N.W. to S.E., and the third 290 m. in length striking S.W. to N.E. The first section, which is connected with the system of the Caucasus, and begins west of Lenkoran in 39° N. and 45° E., is known as the Talish range and has several peaks 9000 to 10,000 ft. in height. It runs almost parallel to the western shore of the Caspian, and west of Astara is only 10 or 12 m. distant from the sea. At the point west of Resht, where the direction of the principal range changes to one of N.W. to S.E., the second section of the Elburz begins, and extends south to beyond Mount Demavend, east of Teheran. South of Resht this section is broken through at almost a right angle by the Safid Rud (White river), and along it runs the principal commercial road between the Caspian and inner Persia, Resht-Kazvin-Teheran. The Elburz then splits its principal ranges running parallel to one another and connected at many places by secondary ranges and spurs. Many peaks of the ranges in this section have an altitude of 11,000 to 13,000 ft., and the elevation of the passes leading over the ranges varies between 7000 and 10,000 ft. The highest peaks are situated in the still unexplored district of Talikan, N.W. of Teheran, and thence eastwards to beyond Mount Demavend. The part of the Elburz immediately north of Teheran is known as the Kuh-i Shimir (mountain of Shimir), from the name of the Shah Mahommed Shimir, its southern aspect; and culminates in the Sar-i Tochal (12,600 ft.). Beyond it, and between the border of Talikan in the N.W. and Mount Demavend in the N.E., are the ranges Azadabur, Kasi, Kachang, Kevendvan, Shahzad, Varzeh, Derbent i Sar and others, with elevations of 12,000 to 13,500 ft., while Demavend towers above them all with its altitude of 10,400 ft. The eastern foot of Demavend is washed by the river Herzab (called Ter river in its upper course), which there breaks through the Elburz in a S.-N. direction from its course to the Caspian, past the city of Amol. The third section of the Elburz, with its principal ranges striking S.W. to N.E., has a length of about 290 m., and ends some distance beyond Bujnurd in northern Khorasan, where it joins the Ala Daghi range, which has a direction to the S.E., and, continuing with various appellations to northern Afghanistan, unites with the Paropamisus. For about two-thirds of its length—from its beginning to Khushe Yailak—the third section consists of three principal ranges connected by lateral ranges and spurs. It also has many peaks over 10,000 ft. in height, and the Nizva mountain on the southern border of the 'unexplored district of Hazarjirib, north of Semnan, and the Shahkuh, between Shahrubad and Astarabad, have an elevation exceeding 11,500 ft. Beyond Khushe Yailak (now a pleasant summer-quarters"), with an elevation of 10,000 ft., are the Kuhl i Buhar (8000) and Kuhl i Suluk (8000), which latter joins the Ala Daghi (11,000).

The northern slopes of the Elburz and the lowlands which lie between them and the Caspian, and together form the provinces of Gilan, Mazendaran and Astarabad, are covered with dense forest and traversed by hundreds (Persian writers say 1562) of perennial rivers and streams. The breadth of the lowlands between the foot of the hills and the sea is from 2 to 25 m., the greatest breadth being in the meridian of Resht in Gilan, and in the districts of Amol, Sar and Barfurush in Mazendaran. The inner slopes and ranges of the Elburz south of the principal watershed, generally the central one of the three principal ranges which are outside of the fertilizing influence of the moisture brought from the sea, have little or no natural vegetation, and those farthest south are, excepting a few stunted cypress, completely arid and bare.

The watered valleys forming the western border of the ranges are produced by the watersheds of the rivers, which with the general verdure refresh the eye. Gurgling water, strips of sward and tall forest trees, backed by green hills, make a scene completely unlike the usual monotony of Persian landscape. The forest scenery much resembles that of England, with fine oaks and greensward. South of the watershed the whole aspect of the landscape is as hideous and disappointing as scenery in Afghanistan. Ridgeafter ridge of bare hill and curtain behind curtain of serrated mountain, sometimes of charming greys and blues, but still all bare and naked, rugged and arid" (Beresford Lovett, Proc. R.G.S., Feb. 1883).

The higher ranges of the Elburz are snow-capped for the greater part of the year, and some, which are not exposed to the refracted heat from the arid districts of inner Persia, are rarely without snow. Water is plentiful in the Elburz, and situated in well-watered valleys and gorges are innumerable flourishing villages, embosomed in gardens and orchards, with extensive cultivated fields and meadows, and at higher altitudes small plateaus, under snow until March or April, afford cool camping grounds to the nomads of the plains, and luxuriant grazing to their sheep and cattle during the summer. (A. H.-S.)

ELCHE, a town of eastern Spain, in the province of Alicante, on the river Vinalaipo. Pop. (1900) 27,308. Elche is the meeting-place of three railways, from Novelda, Alicante and Murcia. It contains no building of high architectural merit, except, perhaps, San Miguel, a college of San Francisco, surmounted by a blue-tiled dome and fine west doorway. But the costume and physiognomy of the inhabitants, the narrow streets and flat-roofed, whitewashed houses, and more than all, the thousands of palm-trees in its gardens and fields, give the place a strikingly Oriental aspect, and render it unique among the cities of Spain. The cultivation of the palm is indeed the principal occupation; and though the dates are inferior to those of the Barbary States, upwards of 25,000 tons of oil are annually exported. The blanched sticks of the date palm are used for the manufacture of the palm Sunday, and after they have received the blessing of the priest they are regarded throughout Spain as certain defences against lightning. Other thriving local industries include the manufacture of oil, soap, flour, leather, alcohol and esparto grass rugs. The harbour of Elche is Santa Pola (pop. 4100), situated 6 m. E.S.E. where the Vinalaipo enters the Mediterranean, after forming the wide lagoon known as the Albufera de Elche. Elche is also the name of a Roman colony of Illici or Illici. From the 8th century to the 13th it was held by the Moors, who finally failed to recapture it from the Spaniards in 1332.

ELCHINGEN, a village of Germany, in the kingdom of Bavaria, not far from the Danube, 5 m. N.E. from Ulm. Here, on the 14th of October 1805, the Austrians under Laudon were
defeated by the French under Ney, who by taking the bridge decided the day and gained for himself the title of duke of Elchingen.

Eldad ben Mahli, also surnamed Had-Dani, Abu-Dani, David-had-Dani, or the Danite, Jewish traveller, was the supposed author of a Jewish travel-narrative of the 9th century a.d., which enjoyed great authority in the middle ages, especially on the question of the Lost Ten Tribes. Eldad first set out to visit his Hebrew brethren in Africa and Asia. His vessel was wrecked, and he fell into the hands of cannibals; but he was saved by his leanness, and by the opportune invasion of a neighbouring tribe. After spending four years with his new captors, he was ransomed by a fellow-countryman, a merchant of the tribe of Issachar. He then (according to his highly fabulous narrative) visited the territory of Issachar, in the mountains of Media and Persia; he also describes the abodes of Zabulon, on the "other side" of the Parun Mountains, extending to Armenia and the Euphrates; of Reuben, on another side of the same mountains; of Ephraim and Half Manasseh, in Arabia, not far from Mecca; and of Simeon and the other half of Manasseh, in Chorazin, six months' journey from Jerusalem. Dan, he declares, sooner than join in Jeroboam's scheme of an Israelite war against Judah, had migrated to Cush, and finally, with the help of Naphthali, Asher, and Gad, had founded an independent Jewish kingdom in the Gold Land of Havilla, beyond Abyssinia. The tribe of Levi had also been miraculously guided, from near Babylon, to Havilla, where they were enclosed and protected by the mystic river Sambation or Sabbation, which on the Sabbath, though calm, was veiled in impenetrable mist, while on other days it ran with a fierce untranscendent current of stones and sand.

Apart from these tales, we have the genuine Eldad, a celebrated Jewish traveller and philologist, who flourished c. a.d. 850-880; to whom the work above noticed is ascribed; who was a native either of S. Arabia, Palestine or Media; who journeyed in Egypt, Mesopotamia, North Africa, and Spain; who spent several years at Kairawân in Tunisia; who died on a visit to Cordova, and whose authority, as to the lost tribes, is supported by a great Hebrew doctor of his own time, Zemah Gaon, the rector of the Academy at Sura (a.d. 884-893). It is possible that a certain relationship exists (as suggested by Epstein and supported by D. H. Müller) between the famous apocryphal Letter of Presbyter John (of c. a.d. 1165) and the narrative of Eldad; but the affinity is not close. Eldad is quoted as an authority on linguistic difficulties by the leading medieval Jewish grammarians and lexicographers.

The work ascribed to Eldad is in Hebrew, divided into six chapters, probably adapted from the original of a Persian chris. The first appeared at Mantua about 1450; the second at Constantinople in 1516; this was reprinted at Venice in 1544 and 1605, and at Jessenitz in 1744. A transliteration by Giraldi was published in Padua in 1565, under the title of Eldad Danius ... de Judaeis clavis eorumque in Asia antiquitate ... imperio, and was afterwards incorporated in the translator's Chrestologia Hebraeorum of 1584; a German version appeared at Prague in 1605, and another at Jessenitz in 1743. In 1838 E. Carmoly edited and translated a fuller recession which he had found in a MS. from the library of Eliezer Ben Hasan, forwarded to him by David Zabach of Morocco (see Relation d'Eldad le Danois, Paris, 1638). Both forms are printed by Dr. Jellinek in his Bet ha-Midrash, vol. ii. p. 102, &c., and iii. p. 6, &c. (Leipzig, 1853-1854). In 1909, Biblica, 1, part 1; 1910, 73. Forst, and 1911, Jacobs, 1, 30; ; Hirsch Graetz, Geschichte der Juden (3rd ed., Leipzig, 1895), v. 239-244; Rossi, Dizionario degli Ebrei; Steinschneider, Cat. Hebreworum Hebraeorum in bibliotheca Biblica, Berlin, 1845. Kittel, Biblia Cyclopaedia (3rd edition, sub nomine); Abr. Epstein, Eldad ha-Dani (Presburg, 1891); D. H. Müller, "Die Recensionen und Versionen des Eldad had-Dani," in Denkschriften d. Wiener Akad. (Phil.-Hist. Cl.), vol. xii. (1892), pp. 1-80.

Elder (Gr. πρεσβύτερον), the name given at different times to a ruler or officer in certain political and ecclesiastical systems of government.

1. The office of elder is in its origin political and is a relic of the old patriarchal system. The unit of primitive society is always the family; the only tie that binds men together is that of kinship. The "elder male parent," to quote Sir Henry Maine, 1 is absolutely supreme in his household. His dominion extends to life and death and is as unqualified over his children and their houses as over his slaves. The tribe, which is a later development, is always an aggregate of families or clans, not a collection of individuals. The union of several clans for common political action, as Robertson Smith says, 2 was produced by the pressure of practical necessity, and always tended towards dissolution when this practical pressure was withdrawn. The only organization for common action was that the leading men of the clans consulted together in time of need, and their influence led the masses with them. Out of these conferences arose the senates of elders found in the ancient states of Semitic and Aryan antiquity alike. 3 With the development of civilization there came a time when age ceased to be an indispensable condition of leadership. The old title was, however, generally retained, e.g. the yāḥāwērē so often mentioned in Homer, the yāḥāwikā of the Dorian states, the senātūs and the prātēs conscriptūs of Rome, the sheikh or elder of Arabia, the elderman of an English borough, the seigneur (Lat. senior) of feudal France.

2. It was through the influence of Judaism that the originally political office of elder passed over into the Christian Church and became ecclesiastical. The Israelites inherited the office from their Semitic ancestors (just as did the Moabites and the Midianites, of whose elders Moses read in Numbers xxii. 7), and traces of it are found throughout their history. Mention is made in Judges vili. 14 of the elders of Succoth whom "Gideon taught with thorns of the wilderness and with briers." It was to the elders of Israel in Egypt that Moses communicated the plan of Yahweh for the redemption of the people (Exodus iii. 16). During the sojourn in the wilderness the elders were the intermediaries between Moses and the people, and it was out of the ranks of these elders that Moses chose a council of seventy "to bear with him the burden of the people" (Numbers xi. 16). The elders were the governors of the people and the administrators of justice. There are frequent references to their work in the latter capacity in the book of Deuteronomy, especially in relation to the following crimes—the disobedience of sons; slander against a wife; the refusal of levirate marriage; manslaughter; and blood-revenge. Their powers were gradually curtailed by (a) the development of the monarchy, to which in course they were in subjection, and which became the court of appeal in questions of law; (b) the appointment of special judges, probably chosen from amongst the elders themselves, though their appointment meant the loss of privilege to the general body; (c) the rise of the priestly orders, which usurped many of the prerogatives that originally belonged to the elders. But in spite of the rise of new authorities, the elders still retained a large amount of influence. We hear of them frequently in the Pentateuch, in Republican period, and even in the Christian Church. It is important to observe that the members of the Sanhedrin in Jerusalem are very frequently termed "elders" or πρεσβύτεροι, and from them the name was taken over by the Church.

3. The name "elder" was probably the first title bestowed upon the officers of the Christian Church—since the word deacon does not occur in connection with the appointment of the Seven in Acts vi. Its universal adoption is due not only to its currency among the Jews, but also to the fact that it was frequently used as the title of magistrates in the cities and villages of Asia Minor. For the history of the office of elder in the early Church and the relation between elders and bishops see Presbyter.

4. In modern times the use of the term is almost entirely confined to the Presbyterian church, the officers of which are always called elders. According to the Presbyterian theory of church government there are two classes of elders—"teaching elders," or those specially set apart to the pastoral office, and "ruling elders," who are laymen, chosen generally by the congregation and set apart by ordinance to be associated with the pastor in the oversight and government of the church.
the word is used without any qualification it is understood to apply to the latter class alone. For an account of the duties, qualifications and powers of elders in the Presbyterian Church see Presbyterianism.

ELDER (O. Eng. eallr; Ger. Hösner; Fr. sureau), the popular designation of the deciduous shrubs and trees constituting the genus Sambucus of the natural order Caprifoliaceae. The common Elder, S. nigra, the bourtree of Scotland, is found in Europe, the north of Africa, Western Asia, the Caucasus, and Southern Siberia; in sheltered spots it attains a height of over 20 ft. The bark is smooth; the shoots are stout and angular, and the leaves glabrous, pinnate, with oval or elliptical leaflets. The flowers, which form dense flat-topped clusters (corymbose cymes), with five main branches, have a cream-coloured, gametopetalous, five-lobed corolla, five stamens, and three sessile stigmas; the berries are purplish-black, globular and three- or four-seeded, and ripen about September. The elder thrives best in moist, well-drained situations, but can be grown in a great diversity of soils. It grows readily from young shoots, which after a year are fit for transplantation. It is found useful for making screen-fences in bleak, exposed situations, and also as a shelter for other shrubs in the outskirts of plantations. By clipping three times a year, it may be made close and compact in growth. The young trees furnish a brittle wood, containing much pitch; the wood of old trees is white, hard and close-grained, polishes well, and is employed for shoemakers' pegs, combs, skewers, mathematical instruments and turned articles. Young elder twigs deprived of pith have from very early times been in request for making whistles, popguns and other toys.

The elder was known to the ancients for its medicinal properties, and in England the inner bark was formerly administered as a cathartic. The flowers (sambuci flores) contain a volatile oil, and serve for the distillation of elder-flower water (aqua sambuci), used in confectionery, perfumes and lotions. The leaves of the elder are employed to impart a green colour to fat and oil (unicentum sambuci foliorum et oleum viride), and the berries for making wine, a common adulterant of port. The leaves and bark emit a sickly odour, believed to be repugnant to insects. Christopher Gullet (Phil. Trans., 1722, lxi. p. 348) recommends that cabbages, turnips, wheat and fruit trees, to preserve them from caterpillars, flies and blight, should be whipped with twigs of young elder. According to German folklore, the hat must be doffed in the presence of the elder-tree; and in certain of the English midland counties a belief was once prevalent that the cross of Christ was made from its wood, which should therefore never be used as fuel, or treated with disrespect (see Quart. Rev. exch., 1834). However, a strong attachment had sprung up between them. On the 18th November 1772 Scott, with the aid of a ladder and an old friend, carried off the lady from her father's house in the Sandhill, across the border to Blacksheds, in Scotland, where they were married. The father of the bridegroom objected not to his son's choice, but to the time he chose to marry; for it was a blight on his son's prospects, depriving him of his fellowship and his chance of church preferment. But while the bride's family refused to hold intercourse with the pair, Mr Scott, like a prudent man and an affectionate father, set himself to make the best of a bad matter, and received them kindly, settling on his son £2000. John returned with his wife to Oxford, and continued to hold his fellowship for what is called the year of grace given after marriage, and added to his income by acting as a private tutor. After a time Mr Surtees was reconciled with his daughter, and made a liberal settlement on his son medieval.

John Scott's year of grace closed without any college living falling vacant; and with his fellowship he gave up the church and turned to the study of law. He became a student at the Middle Temple in January 1773. In 1776 he was called to the bar, intending at first to establish himself as an advocate in his native town, a scheme which his early success led him to abandon, and he soon settled to the practice of his profession in London, Andrew Bowers of Gibushe, to the patronage of whose house the rise of the Scott family was largely owing. Bowers having contested Newcastle and lost it, presented an election petition against the return of his opponent. Young Scott was retained as junior counsel in the case, and though he lost the petition he did not fail to improve the opportunity which it afforded for displaying his talents. This engagement, in the commencement of his
soon, however, broke up the Grenville administration; and in the spring of 1807 Lord Eldon once more, under Lord Liverpool’s administration, returned to the woolpack, which, from that time, continued to occupy the cabinet, and being in all but name prime minister of England. It was not till April 1827, when the premiership, vacant through the paralysis of Lord Liverpool, fell to Canning, the chief advocate of Roman Catholic emancipation, that Lord Eldon, in the seventy-sixth year of his age, finally resigned the chancellorship.

When, after the two short administrations of Canning and Goderich, it fell to the duke of Wellington to construct a cabinet, Lord Eldon, expected to be included, if not as chancellor, at least in some important office, but he was overlooked, at which he was much chagrined. Notwithstanding his frequent protests that he did not covet power, but longed for retirement, we find him again, so late as 1835, within three years of his death, in hopes of office under Peel. He spoke in parliament for the last time in July 1834.

In 1821 Lord Eldon had been created Viscount Encombe and earl of Eldon by George IV, whom he managed to conciliate, partly, no doubt, by espousing his cause against his wife, whose advocate he had formerly been, and partly through his reputation for zeal against the Roman Catholics. In the same year his brother William, who from 1798 had filled the office of judge of the High Court of Admiralty, was raised to the peerage under the title of Lord Stowell.

Lord Eldon’s wife, his dear “Bessy,” his love for whom is a beautiful feature in his life, died before him, on the 26th June 1834. By nature she was of simple character, and by habits acquired during the early portion of her husband’s career almost a recluse. Two of their sons reached maturity—John, who died in 1805, and William Henry John, who died unmarried in 1832. Lord Eldon himself survived almost all his immediate relations. His brother William died in 1836. He himself died in London on the 21st of January 1838, leaving behind him two daughters, Lady Frances Bancks and Lady Elizabeth Repton, and a grandson John (1808-1854), who succeeded him as second earl, the title subsequently passing to the latter’s son John (b. 1846).

Lord Eldon was no legislator—his one aim in politics was to keep in office, and maintain things as he found them; and almost the only laws he helped to pass were laws for popular coercion. For nearly forty years he fought against every improvement in law, or in the constitution—calling God to witness, on the smallest proposal of reform, that he foresaw from it the downfall of his country. Without any political principles, properly so called, and without interest in or knowledge of foreign affairs, he maintained himself and his party in power for an unprecedented period by his great tact, and in virtue of his two great political properties—of zeal against every species of reform, and zeal against the Roman Catholics. To pass from his political to his judicial character is to shift to ground on which his greatness is universally acknowledged. His judgments, which have received as much praise for their accuracy as for their clumsiness and uncoyness, fill a small library. But though intimately acquainted with every nook and cranny of the English law, he never carried his studies into foreign fields, from which to enrich our legal literature; and it must be added that against the excellence of his judgments, in too many cases, must be set off the hardships, worse than injustice, that arose from his prolonged delays in pronouncing them. A consummate judge and the narrowest of politicians, he was doubt on the bench, and promptness itself in the political arena. For literature, for art, he had no feeling. What intervals of leisure he enjoyed from the cares of office he filled up with newspapers and the gossip of old cronies. Nor were his intimate associates men of refinement and taste; they were rather good fellows who quietly enjoyed a good bottle and a joke; he uniformly avoided encounters of wit with his equals. He is said to have been quicker to receive than to reciprocate hospitality; but his mean establishment and mode of life are explained by the retired habits of his wife, and her
EL DORADO—ELATIE A SCHOOL

Dislike of company. His manners were very winning and courtly, and in the circle of his immediate relatives he is said to have always behaved in a gentlemanly manner. "In his person," says Lord Campbell, "Lord Eldon was about the middle size, his figure light and athletic, his features regular and handsome, his eye bright and full, his smile remarkably benevolent, and his whole appearance prepossessing. The advance of years rather increased than detracted from these personal advantages. As he sat on the judgment-seat, the deep thought betrayed in his furrowed brow—the large eyebrows, overhanging his eyes—that seemed to regard more what was taking place within than around him—his calmness, that would have assumed a character of sternness but for its perfect placidity—his dignity, repose and venerable age, tended at once to win confidence and to inspire respect" (Townsend). He had a voice both sweet and deep-toned, and its effect was not injured by his Northumbrian burr, which, though strong, was entirely free from harshness and vulgarity.

EL DORADO (Spa. "the gilded one.") A name applied, first, to the king or chief priest of a South American tribe who was said to cover himself with gold dust at a yearly religious festival held near Santa Fe de Bogotá; next, to a legendary city called Manoa or Omoa; and lastly, to a mythical country in which gold and precious stones were found in fabulous abundance. The legend, which has never been traced to its ultimate source, had many variants, especially as regards the situation attributed to Manoa. It induced many Spanish explorers to lead expeditions in search of treasure, but all failed. Among the most famous were the expeditions undertaken by Diego de Ordaz, whose lieutenant Martinez claimed to have been rescued from shipwreck, conveyed inland, and entertained at Omoa by "El Dorado" himself (1531); and the journeys of Orellana (1540—1541), who passed down the Rio Napo to the valley of the Amazon; that of Philip von Hutten (1541—1543), who led an exploring party from Coro on the coast of Caracas; and of Gonzalo Ximenes de Quesada (1569), who started from Santa Fe de Bogotá. Sir Walter Raleigh, who resumed the search in 1595, described Manoa as a city on Lake Parimá in Guiana. This lake was marked on English and other maps until its existence was disproved by A. von Humboldt (1769—1859). Meanwhile the name of El Dorado came to be used metaphorically of any place where wealth could be rapidly acquired. It was given to a county in California, and to towns and cities in various states. See also frequent occurrences to regard more what was taking place within than around him—his calmness, that would have assumed a character of sternness but for its perfect placidity—his dignity, repose and venerable age, tended at once to win confidence and to inspire respect" (Townsend). He had a voice both sweet and deep-toned, and its effect was not injured by his Northumbrian burr, which, though strong, was entirely free from harshness and vulgarity.

ELDUAYEN, José, 1st Marquis de la Merced (1823—1898). Spanish politician, was born in Madrid on the 22nd of June 1823. He was educated in the capital, took the degree of civil engineer, and as such directed important works in Asturias and Galicia, entered the Cortes in 1856 as deputy for Vigo, and sat in all the parliaments until 1867 as member of the Union Liberal with Marshal O’Donnell. He attacked the Mitrañofes cabinet in 1864, and became under-secretary of the home office when Canovas was minister in 1865. He was a member of the state in 1866, and in 1866 assisted the other members of the Union Liberal in preparing the revolution. In the Cortes of 1872 he took much part in financial debates. He accepted office as member of the last Sagasta cabinet under King Amadeus. On the proclamation of the republic Elduayen very earnestly co-operated in the Alphonist conspiracy, and endeavoured to induce the military and politicians to work together. He went abroad to meet and accompany the prince after the pronunciamiento of Marshal Campos, landed with him at Valencia, was made governor of Madrid, a marquis, grand cross of Charles III., and minister for the colonies in 1873. He accepted the portfolio of foreign affairs in the Canovas cabinet from 1883 to 1885, and was made a life senator. He always prided himself on having been one of the five members of the Cortes of 1870 who voted for Alphonso XII. when that parliament elected Amadeus of Savoy. He died at Madrid on the 8th of June 1898.

ELEANOR OF AQUITAINE (c. 1122—1204), wife of the English king Henry II., was the daughter and heiress of Duke William X. of Aquitaine, whom she succeeded in April 1137. In accordance with arrangements made by her father, she at once married Prince Louis, the heir to the French crown, and a month later her husband became king of France under the title of Louis VII. Eleanor bore Louis two daughters but no sons. This was probably the reason why their marriage was annulled by mutual consent in 1154, but contemporary scandal-mongers attributed the separation to the king's jealousy. It was alleged that, while accompanying her husband on the Second Crusade (1146—1149), Eleanor had been unduly familiar with her uncle, Raymond of Antioch. Chronology is against this hypothesis, since Louis and she lived on good terms together for two years after the Crusade. There is still less ground for the supposition that Henry of Anjou, whom she married immediately after the divorce, had been her lover before it. This second marriage, with a youth some years her junior, was purely political. The duchy of Aquitaine required a strong ruler, and the union with Anjou was eminently desirable. Louis, who had hoped that Aquitaine would descend to his daughters, was mortified and alarmed by the Angevin marriage; all the more so when Henry of Anjou succeeded to the English crown in 1154. From this event dates the beginning of the secular strife between England and France which runs like a red thread through medieval history.

Eleanor bore to her second husband five sons and three daughters; John, the youngest of their children, was born in 1166. But her relations with Henry passed gradually through indifference to hatred. Henry was an unfaithful husband, and Eleanor supported her sons in their great rebellion of 1173. Throughout the latter years of the reign she was kept in a sort of honourable confinement. It was during her captivity that Henry formed his connexion with Rosamond Clifford, the Fair Rosamond of romance. Eleanor, therefore, can hardly have been responsible for the death of this rival, and the romance of the poisoned bowl appears to be an invention of the next century.

Under the rule of Richard and John the queen became a political personage of the highest importance. To both her sons the popularity which she enjoyed in Aquitaine was most valuable. But in other directions also she did good service. She helped to frustrate the conspiracy with France which John concocted with Richard's captain, De Forville, and the king and the Prince, thus saving for John the succession which he had forfeited by his misconduct. In 1190 she crushed an Angevin rising in favour of John's nephew, Arthur of Brittany. In 1200 she negotiated a marriage between her grand-daughter, Blanche of Castile, and Louis of France, the grandson of her first husband. It was through her staunch defence of Mirabeau in Poitou that John got possession of his nephew's person. She died on the 1st of April 1205, and was buried at Fontevrault. Although a woman of strong passions and great abilities she is, historically, less important as an individual than as the heiress of Aquitaine, a part of which was, through her second marriage, united to England for some four hundred years.

ELATIE A SCHOOL, a Greek school of philosophy which came into existence towards the end of the 6th century B.C., and ended with Melissus of Samos (fl. c. 450 B.C.). It took its name from Elea, a Greek city of lower Italy, the home of its chief exponents, Parmenides and Zeno. Its foundation is often attributed to Xenophanes of Colophon, but, although there is much in his speculations which formed part of the later Eleatic doctrine, it is probably more correct to regard Parmenides as the founder of the school. At all events, it was Parmenides who gave it its fullest development. The main doctrines of the Eleatics were evolved in opposition, on the one hand, to the
physical theories of the early physical philosophers who explained all existence in terms of primary matter (see IONIAN SCHOOL) and, on the other hand, to the theory of Heraclitus that all existence may be summed up as perpetual change. As against these theories the Eleatics maintained that the true essence of things lies in the conception of a universal unity of being. The senses with their changing and inconsistent reports cannot cognize this unity; it is by thought alone that we can pass beyond the false appearances of sense and arrive at the knowledge of being, at the fundamental truth that “the All is One.” There can be no creation, for being cannot come from not-being; a thing cannot arise from that which is different from it. The errors that mislead arise as well from the ambiguous use of the verb “to be,” which may imply existence or be merely the copula which connects subject and predicate. In these main contentions the Eleatic school achieved a real advance, and paved the way to the modern conception of metaphysics. Xenophanes in the middle of the 6th century had made the first great attack on the crude mythology of early Greece, including in his onslaught the whole anthropomorphic system enshrined in the poems of HOMER and HESIOD. In the hands of Parmenides this spirit of free thought developed on metaphysical lines. Subsequently, whether from the fact that such bold speculations were obnoxious to the general sense of propriety in Elea, or from the inferiority of its leaders, the school degenerated into verbal disputes as to the possibility of motion, and similar academic trifling. The best work of the school was absorbed in the Platonic metaphysics (see E. Caird, *Evolution of Theology in the Greek Philosophers*, 1906). See further the articles on Xenophon; Parmenides; Zeno (of Elea); Melissus, with the works there quoted; also the histories of philosophy by Zeller, Gomperz, Windelband, &c.

**ELECAMPANE** (Med. Lat. *Eauca Campana*), a perennial composite plant, the *Inula Helenium* of botanists, which is common in many parts of Britain, and ranges throughout central and southern Europe, and in Asia as far eastwards as the Himalayas. It is a rather rigid herb, the stem of which attains a height of from 3 to 5 ft.; the leaves are large and toothed, the lower ones stalked, the rest embracing the stem; the flowers are yellow, 2 in. broad, and have many rays, each three-notched at the extremity. The root is thick, branching and mucilaginous, and has a warm, bitter taste and a camphoraceous odour. For medicinal purposes it should be procured from plants not more than two or three years old. Besides *Inula*, *Cephalanthera*, a body isomeric with starch, the root contains *helencin*, *CaCO₃*, a steatoptone, which may be prepared in white calcareous crystals, insoluble in water, but freely soluble in alcohol. When freed from the accompanying inula-camphor by repeated crystallization from alcohol, helencin melts at 110 C°. By the ancients the root was employed both as a medicine and as a condiment, and in England it was formerly in great repute as an aromatic tonic and stimulant of the secretory organs. "The fresh roots of elecampane preserved with sugar, or made into a syrup or conserve," are recommended by John Parkinson in his *Theatrum Botanicum* as "very efficacious for a cold and windy stomach, and the prickings and stitches therein or in the sides caused by the Spleene, and to holpe the cough, shortness of breath, and wheesing in the Lungs." As a drug, however, the root is now seldom resorted to except in veterinary practice, though it is undoubtedly possessed of antiseptic properties. In France and Switzerland it is used in the manufacture of absinthe.

**ELECTION** (from Lat. *elegere*, to pick out), the method by which a choice or selection is made by a free and warm body (the electors or electorate) of some person to fill a certain office or dignity. The procedure itself is called an election. Election, as a special form of selection, is naturally a loose term covering many subjects; but except in the theological sense (the doctrine of election), as employed by Calvin and others, for the choice by God of His "elect," the legal sense (see ELECTION, in law, below), and occasionally as a synonym for personal choice (one’s own "election"), it is confined to the selection by the preponderating vote of some properly constituted body of electors of one of two or more candidates, sometimes for admission only to some private social position (as in a club), but more particularly in connexion with public representative positions in political government. It is thus distinguished from arbitrary methods of appointment, either where the right of nominating rests in an individual, or where pure chance (such as selection by lot) dictates the result. The part played by different forms of election in history is alluded to in numerous articles in this work, dealing with various countries and various subjects. It is only necessary here to consider certain important features in the elections, as ordinarily understood, namely, the exercise of the right of voting for political and municipal offices in the United States: Political Institutions. For practical details as to the conduct of political elections in England reference must be made to the various text-books on the subject; the candidate and his election agent require to be on their guard against any false step which might invalidate his return.

*Law in the United Kingdom.*—Considerable alterations have been made in recent years in the law of Great Britain and Ireland relating to the procedure at the parliamentary and municipal elections, and to election petitions.

As regards parliamentary elections (which may be either the "general election," after a dissolution of parliament, or "by-elections," when casual vacancies occur during its continuance), the most important of the amending statutes is the *Corrupt and Illegal Practices Act* 1883. This act, and the *Parliamentary Elections Act* 1868, as amended by it, and other enactments dealing with corrupt practices, are temporary acts requiring annual renewal. As regards municipal elections, the *Corrupt Practices (Municipal Elections) Act* 1872 has been repealed by the *Municipal Corporations Act* 1883 for England, and by the *Local Government (Ireland) Act* 1888 for Ireland. The governing enactments for England are now the *Municipal Corporations Act* 1882, part iv., and the *Municipal Elections (Corrupt and Illegal Practices) Act* 1884, the latter annually renewable. The provisions of these enactments have been applied with necessary modifications to municipal and other local government elections in Ireland by orders of the Irish Local Government Board made under powers conferred by the *Local Government (Ireland) Act* 1886. In Scotland the law regulating municipal and other local government elections is now to be found in the *Elections (Scotland) (Corrupt and Illegal Practices) Act* 1890.

The alterations in the law have been in the direction of greater strictness in regard to the conduct of elections, and the control in the courts of the proceedings on election petitions. Various acts and payments which were previously lawful in the absence of any corrupt bargain or motive are now altogether forbidden under the name of "illegal practices" as distinguished from "corrupt practices." Failure on the part of a parliamentary candidate or his election agent to comply with the requirements of the law in any particular is sufficient to invalidate the return (see the articles BREBRY and CORRUPT PRACTICES). Certain relaxations are, however, allowed in consideration of the difficulty of absolutely avoiding all deviation from the strict rules laid down. Thus, where the judges who try an election petition report that there has been treating, undue influence, or any illegal practice by the candidate or his election agent, but that it was trivial, unimportant and of a limited character, and contrary to the orders and without the sanction or connivance of the candidate or his election agent, and that the candidate or his election agent took all reasonable means for preventing corrupt and illegal practices, the election was otherwise free from such practices on their part, the election will not be avoided. The court has also the power to relieve from the consequences of certain innocent contraventions of the law caused by inadvertence or miscalculation.

The inquiry into a disputed parliamentary election was formerly conducted before a committee of the House of Commons, chosen as nearly as possible from both sides of the House for that particular business. The decisions of these tribunals laboured
ELECTION

under the suspicion of being prompted by party feeling, and by an act of 1868 the jurisdiction was finally transferred to judges of the High Court, notwithstanding the general unwillingness of the bench to act as a class of business which they feared might bring their integrity into dispute. Section 11 of the act ordains, alia, that the trial of every election petition shall be conducted before a puisne judge of one of the common law courts at Westminster and Dublin; that the said courts shall each select a judge to be placed on the rota for the trial of election petitions; that the said judges shall try petitions standing for trial according to seniority or otherwise, as they may agree; that the trial shall take place in the county or borough to which the petition refers, unless the court should think it desirable to hold it elsewhere. The judge shall determine "whether the member whose return is complained of, or any and what other person, was duly returned and elected, or whether the election was void," and shall certify his determination to the speaker. When corrupt practices have been charged the judge shall also report (1) whether any such practice has been committed by or with the knowledge or consent of any candidate, and the nature thereof; (2) the names of persons proved to have been guilty of any corrupt practice; and (3) whether corrupt practices have extensively prevailed at the election. Questions of law were to be referred to the decision of the court of common pleas. On the abolition of that court by the Judicature Act 1873, the jurisdiction was transferred to the common pleas division, and again on the abolition of that division was transferred to the king's bench division, in which it is now vested. The rota of judges for the trial of election petitions is also supplied by the king's bench division. The trial now takes place before two judges instead of one; and, when necessary, the number of judges on the rota may be increased. Both the judges who try a petition are to sign the certificates to be made to the speaker. If they differ as to the validity of a return, they are to state such a difference in their certificate, and the return is to be held good; if they differ as to a report on any other matter, they are to certify their difference and make no report on such matter. The director of public prosecutions attends the trial personally or by representative. It is his duty to watch the proceedings in the public interest, to issue summonses to witnesses whose evidence is desired by the court, and to prosecute before the election court or elsewhere those persons whom he thinks to have been guilty of corrupt or illegal practices at the election in question. If an application is made for leave to withdraw a petition, copies of the affidavits in support are to be delivered to him; and he is entitled to attend and to call witnesses in opposition to the application. Witnesses are not excused from answering criminating questions; but their evidence cannot be used against them in any proceedings except criminal proceedings for perjury in respect of that evidence. If a witness answers truly all questions which he is required by the court to answer, he is entitled to receive a certificate of indemnity, which will save him from all proceedings for any offence under the Corrupt Practices Acts committed by him before the date of the certificate or in relation to the election, except proceedings to enforce any incapacity incurred by such offence. An application for leave to withdraw a petition must be supported by affidavits from all the parties to the petition and their solicitors, and by the election agents of all of the parties who were candidates at the election. Each of these affidavits is to state that to the best of the deponent's knowledge and belief there has been no agreement and no terms or undertakings made or entered into as to the withdrawal, or, if any agreement has been made, shall state its terms. The applicant and his solicitor are also to state in their affidavits the grounds on which the petition is sought to be withdrawn. If any person makes an agreement for the withdrawal of a petition in consideration of a money payment, or of the promise that the seat shall be vacated or another petition withdrawn, or omits to state in his affidavit that he has made an agreement, lawful or unlawful, for the withdrawal, he is guilty of an indictable offence. The report of the judges to the speaker is to contain particulars as to illegal practices similar to those previously required as to corrupt practices; and they are to report further whether any candidate has been guilty by his agents of an illegal practice, and whether certificates of indemnity have been given to persons reported guilty of corrupt or illegal practices.

The Corrupt Practices Acts apply, with necessary variations in details, to parliamentary elections in Scotland and Ireland. The amendments in the law as to municipal elections are generally similar to those which have been made in parliamentary election law. The procedure on trial of petitions is substantially the same, and wherever no other provision is made by the acts or rules the procedure on the trial of parliamentary election petitions shall be followed. Petitions against municipal elections were dealt with in 35 & 36 Vict. c. 60. The election judges appoint a number of barristers, not exceeding five, as commissioners to try such petitions. No barrister can be appointed who is of less than fifteen years' standing, or a member of parliament, or holder of any office of profit (other than that of recorder) under the crown; nor can any barrister try a petition in any borough in which he is recorder or in which he resides, or which is included in his circuit. The barrister sits without a jury. The provisions are generally similar to those relating to parliamentary elections. The petition may allege that the election was avoided as to the borough or ward on the ground of general bribery, &c., or that the election of the person petitioned against was avoided by corrupt practices, or by personal disqualification, or that he had not the majority of lawful votes. The commissioner who tries a petition sends to the High Court a certificate of the result, together with reports as to corrupt and illegal practices, &c., similar to those made to the speaker by the judges who try a parliamentary election petition. The Municipal Elections (Corrupt and Illegal Practices) Act 1884 applied to school board elections subject to certain variations, and has been extended by the Local Government Act 1888 to county council elections, and by the Local Government Act 1894 to elections by parochial electors. The law in Scotland is on the same lines, and extends to all non-parliamentary elections, and, as has been stated, the English statutes have been applied with adaptations to all municipal and local government elections in Ireland.

United States.—Elections are much more frequent in the United States than they are in Great Britain, and they are also more complicated. The terms of elective officers are shorter; and as there are also more offices to be filled, the number of persons to be voted for is necessarily much greater. In the year of a presidential election the citizen may be called upon to vote at one time for (1) National candidates—president and vice-president; (2) state candidates—governor, members of the state legislature, attorney-general, treasurer, &c.; (3) county candidates—sheriff, county judges, district attorney, &c.; (4) municipal or town candidates—mayor, aldermen, selectmen, &c. The number of persons actually voted for may therefore be ten or a dozen, or it may be many more. In addition, the citizen is often called upon to vote yes or nay on questions such as amendments to the state constitutions, granting of licences, and approval or disapproval of new municipal undertakings. As there may be, and generally is, more than one candidate for each office, and as all elections are now, and have been for many years, conducted by ballot, the total number of names to appear on the ballot may be one hundred or may be several hundred. These names are arranged in different ways, according to the laws of the different states. Under the Massachusetts law, which is considered the best by reformers, the names of candidates for each office are arranged alphabetically on a "blanket" ballot, as it is called from its size, and the elector places a mark opposite the names of such candidates as he may wish to vote for. Other states, New York for example, have the blanket system, but the names of the candidates are arranged in party columns. Still other states allow the grouping on one ballot of all the candidates of a single party, and there would be therefore as many separate ballots in such states as there were parties in the field.
The qualifications for voting, while varying in the different states in details, are in their main features the same throughout the Union. A residence in the state is required of from three months to two years. Residence is also necessary, but for a shorter period, in the county, city or town, or voting precinct. A few states require the payment of a poll tax. Some require that especially the ignorant one, remains ineligible to the franchise and his institution. This latter qualification has been introduced into several of the Southern states, partly at least to disqualify the ignorant coloured voters. In all, or practically all, the states idiots, convicts and the insane are disqualified; in some states paupers; in some of the Western states the Chinese. In some states women are allowed to vote on certain questions, or for the candidates for certain offices, especially school officials; and in four of the Western states women have the same rights of suffrage as men. The number of those who are qualified to vote, but do not avail themselves of the right, varies greatly in the different states and according to the interest taken in the election.

As a general rule, but subject to exceptions, the national elections call out the largest number, the state elections next, and the local elections the smallest number of voters. In an exciting national election between 80 and 90% of the qualified voters actually vote, a proportion considerably greater than in Great Britain or Germany.

The tendency of recent years has been towards a decrease both in the number and in the frequency of elections. A president and vice-president are voted for every fourth year, in the years divisible by four, on the first Tuesday following the first Monday of November. Members of the national House of Representatives are chosen for two years on the even-numbered years. State and local elections take place in accordance with state laws, and may or may not be on the same day as the national elections. Originally the rule was for the states to hold annual elections; in fact, so strongly did the feeling prevail of the need in a democratic country for frequent elections, that the maxim "where annual elections end, tyranny begins," became a political proverb. But opinion gradually changed even in the older or Eastern states, and in 1809 Massachusetts and Rhode Island were the only states in the Union holding annual elections for governor and both houses of the state legislature. In the Western states especially state officers are chosen for longer terms—indeed the case of the governor often for four years—and the number of elections has correspondingly decreased. Another cause of the decrease in the number of elections is the growing practice of holding all the elections of any year on one and the same day. Before the Civil War Pennsylvania held its state elections several months before the national elections. Ohio and Indiana, until 1885 and 1881 respectively, held their state elections in October, whereas in October of that year Vermont and Arkansas keep to September. The selection of one day in the year for all elections held in that year has resulted in a considerable decrease in the total number.

Another tendency of recent years, but not so pronounced, is to hold local elections in what is known as the "off" year; that is, on the odd-numbered year, when no national election is held. The object of this reform is to encourage independent voting. The average American citizen is only too prone to carry his national political predilections into local elections, and to vote for the local nominees of his party, without regard to the question of fitness of candidates and the fundamental difference of issues involved. This tendency to vote the entire party ticket is the more pronounced because under the system of voting in use in many of the states all the candidates of the party are arranged on one ticket, and it is much easier to vote a straight or unalterable ticket than to change or "scotch" it. Again, the voter, especially the ignorant one, frequently, without knowing it, casts his ticket, in some way he should fail to comply with the technicalities of the law and his vote be lost. On the other hand, if local elections are held on the "off" or odd year, and there be no national or state candidates, the voter feels much more free to select only those candidates whom he considers best qualified for the various offices.

On the important question of the purity of elections it is difficult to speak with precision. In many of the states, especially those with an enlightened public spirit, such as most of the New England states and many of the North-Western, the elections are fairly conducted, there being no intimidation at all, little or no bribery, and an honest count. It can safely be said that through the Union as a whole the tendency of recent years has been definitely towards greater honesty of elections. This is owing to a number of causes: (1) The selection of a single day for all elections, and the consequent immense number voting on that day. Some years ago, when for instance the Ohio and Indiana elections were held a few weeks before the general election, each party strained every nerve to carry them, for the sake of prestige and the influence on other states. In fact, presidential elections were often felt to turn on the result in these early voting states, and, the party managers were none too scrupulous in the means employed to carry them. Bribery has decreased in such states since the change of election day to that of the rest of the country.

(2) The enactment in most of the states of the Australian or secret ballot (q.v.) laws. These have led to the secrecy of the ballot, and hence to a greater or less extent have prevented intimidation and bribery. (3) Educational or other such test, more particularly in the Southern states, the object of which is to exclude the coloured, and, generally the ignorant, from the polls. In those southern states in which the coloured vote was large, and still more in those in which it was the majority, it was felt among the whites that intimidation or ballot-box stuffing was justified by the necessity of white supremacy. With the elimination of the coloured vote by educational or other tests the honesty of elections has increased. (4) The enactment of new and more stringent registration laws. Under these laws only those persons are allowed to vote whose names have been placed on the rolls a certain number of days or months before election. These rolls are open to public inspection, and the names may be challenged at the polls, and "colonization" or repeating is therefore almost impossible. (5) The reform of the civil service and the gradual elimination of the vicious principle of "to the victors belong the spoils." With the reform of the civil service elections become less a scramble for office and more a contest of political or economic principle. They bring into the field, therefore, a better class of candidates. (6) The enactment in a number of states of various other laws for the prevention of corrupt practices, for the publication of campaign expenses, and for the prohibition of party workers from coming within a certain specified distance of the polls. In the state of Massachusetts, for instance, an act passed in 1892, and subsequently amended, provides that political committees shall file a full statement, duly sworn to, of all campaign expenditures made by them. The act makes all public election expenses kept as of Oct. 6th, annually, and also covers nominations by caucuses and conventions as well. Apart from his personal expenses such as postage, travelling expenses, &c., a candidate is prohibited from spending anything himself to promote either his nomination or his election, but he is allowed to contribute to the treasury of the political committee. The law places no limit on the amount that these committees may spend. The reform sought by the law is thorough publicity, and not only are details of receipts and expenditures to be published, but the names of contributors and the amount of their contributions. In the state of New York the act which seeks to prevent corrupt practices relies in like manner on the efficacy of publicity, but it is less effective than the Massachusetts law in that it provides simply for the filing by the candidates themselves of sworn statements of their own expenses. There is nothing to prevent their contributing to political committees, and the financial methods and the amounts expended by such committees are not made public. But behind all these facts there lies a still greater one of a healthier public spirit. In the reaction following the Civil War all reforms halted. In recent years, however, a new and healthier interest has sprung up in things political; and one result of this improved civic spirit is seen in the various laws for purification of elections. It may now be safely affirmed that in the majority of states the elections are honestly conducted; that intimidation, bribery,
stuffing of the ballot boxes or other forms of corruption, when they exist, are owing in large measure to temporary or local causes; and that the tendency of recent years has been towards a decrease in all forms of corruption.

The expenses connected with elections, such as the renting and preparing of the polling-places, the payment of the clerks and other officers who conduct the elections and count the vote, are borne by the community. A candidate therefore is not, as far as the law is concerned, liable to any expense whatever. As a matter of fact he does commonly contribute to the party treasury, though in the case of certain candidates, particularly those for the presidency and for judicial offices, financial contributions are not general. The amount of a candidate's contribution varies greatly, according to the office sought, the state in which he lives, and his private wealth. On one occasion, in a district in New York, a candidate for Congress is credibly believed to have spent at one election $50,000. On the other hand, in a Congressional election in a certain district in Massachusetts, the only expenditure of one of the candidates was for the two cent stamp placed on his letter of acceptance. No estimate of the average amount expended can be made. It is, however, the conclusion of Mr. Bryce, in his American Commonwealth, that as a rule a seat in Congress costs the candidate less than a seat for a county division in the House of Commons. (See also Baker.)

Election, in English law, the obligation imposed upon a party by courts of equity to choose between two inconsistent or alternative rights or claims in cases where there is a clear intention of the person from whom he derives one that he should not enjoy both. Thus a testator died seized of property in fee simple and in fee tail—he had two daughters, and devised the fee simple property to one and the entailed property to the other; the first one claimed to have her share of the entailed property as coparcener and also to retain the benefit she took under the will. It was held that she was put to her election whether she would take under the will and renounce her claim to the entailed property or take against the will, in which case she must renounce the benefits she took under the will in so far as was necessary to compensate her sister. As the essence of the doctrine is compensation, a person electing against a document does not lose all his rights under it, but the court will sequester so much only of the benefit intended for him as will compensate the persons disappointed by his election. For the same reason it is necessary that there should be a free and disposable fund passing by the instrument from which compensation can be made in the event of election against the will. If, therefore, a man having a special power of appointment appoint the fund equally between two persons, one being an object of the power and the other not an object, no question of election arises, but the appointment to the object is bad.

Election, though generally arising in cases of wills, may also arise in the case of a deed. There is, however, a distinction to be observed. In the case of a will a clear intention on the part of the testator that he meant to dispose of property not his own must be shown, and parol evidence is not admissible as to this. In the case of a deed, however, no such intention need be shown, for if a deed confers a benefit and imposes a liability on the same person he cannot be allowed to account the one and reject the other, but it must be distinguished from cases where two separate gifts are given to a person, one beneficial and the other onerous. In such a case no question of election arises and he may take the one and reject the other, unless, indeed, there are words used which make the one conditional on the acceptance of the other.

Election is either express, i.e., by deed, or implied; in the latter, it is often a question of considerable difficulty whether there has in fact been an election or not; each case must depend upon the particular circumstances, but quite generally it may be said that the person who has elected must have been capable of electing, aware of the existence of the doctrine of election, and have had the opportunity of satisfying himself of the relative value of the properties between which he has elected. In the case of infants the court will sometimes elect after an inquiry as to which course is the most advantageous, or if there is no immediate urgency, will allow the matter to stand over till the infant attains his majority. In the cases of married women and lunatics the courts will exercise the right for them. It sometimes happens that the parties have so dealt with the property that it would be inequitable to disturb it; in such cases the court will not interfere in order to allow of election.

Electoral Commission. In United States history, a commission created to settle the disputed presidential election of 1876. In this election Samuel J. Tilden, the Democratic candidate, received 184 uncontested electoral votes, and Rutherford B. Hayes, the Republican candidate, 163. The states of Florida, Louisiana, Oregon and South Carolina, with a total of 22 votes, each sent in two sets of electoral ballots, and from each of these states except Oregon one set gave the whole vote to Tilden and the other gave the whole vote to Hayes. From Oregon one set of ballots gave the three electoral votes of the state to Hayes; the other gave two votes to Hayes and one to Tilden.

The election of a president is a complex proceeding, the method being indicated particularly in the Constitution, and being partly left to Congress and partly to the states. The manner of selecting the electors is left to state law; the electoral ballots are sent to the president of the Senate, who "shall, in the presence of the Senate and House of Representatives, open all certificates, and the votes shall then be counted." Concerning this provision many questions of vital importance arose in 1876: Did the president of the Senate count the votes, the houses being mere witnesses; or did the houses count them, the president's duties being merely ministerial? Did counting imply the determination of what should be counted, or was it a mere arithmetical process? that is, did the Constitution itself afford a method of settling disputed returns, or was this left to legislation by Congress? Might Congress or an officer of the Senate go behind a state's certificate and review the acts of its certifying officials? Might it go further and examine into the choice of electors? And if it had such powers, might it delegate them to a commission? As regards the procedure of Congress, it seems that, although in early years the president of the Senate not only performed or overlooked the electoral count but also exercised discretion in some matters very important in 1876, Congress early began to assert power, and, at least from 1821 onward, controlled the count, claiming complete power. The fact, however, that the Senate in 1876 was controlled by the Republicans and the House by the Democrats, lessened the chances of any harmonious settlement of these questions by Congress. The country seemed on the verge of civil war. Hence it was that the Congress in January 1877, Congress created the Electoral Commission to pass upon the contested returns, giving it "the same powers, if any" possessed by itself in the premises, the decisions to stand unless rejected by the two houses separately. The commission was composed of five Democratic and five Republican Congressmen, two justices of the Supreme Court of either party, and a fifth justice chosen by these four. As its members of the commission the Senate chose G. F. Edmunds of Vermont, O. P. Morton of Indiana and F. T. Frelinghuysen of New Jersey (Republicans); and A. G. Thurman of Ohio and T. F. Bayard of Delaware (Democrats). The House chose Henry B. Payne of Ohio, Eppa Hunton of Virginia, and Josiah G. Abbott of Massachusetts (Democrats); and George F. Hoar of Massachusetts and James A. Garfield of Ohio (Republicans). The Republican judges were William Strong and Samuel F. Miller; the Democratic, Nathan Clifford and Stephen J. Field. These four, together with the five Republican members, i.e., Joseph P. Bradley, 1 The election of a vice-president was, of course, involved also. William A. Wheeler was the Republican candidate, and Thomas A. Hendricks the Democratic. 2 A second set of electoral ballots had also been sent in from Vermont, where Hayes had received a popular majority vote of 24,000. As these ballots had been transmitted in an irregular manner, the president of the Senate refused to receive them, and was sustained in this action by the upper House.
ELECTORS

173

The popular vote seemed to indicate that Hayes had carried South Carolina and Oregon, and Tilden Florida and Louisiana. It was evident, however, that Hayes could secure the 185 votes necessary to elect only by gaining every disputed ballot. As the choice of Republican electors in Louisiana had been accomplished by the rejection of several thousand Democratic votes by a Republican returning board, the Democrats insisted that the commission should go behind the returns and correct injustice; the Republicans declared that the state's action was final, and that to go behind the returns would be invading its sovereignty. When this matter came before the commission it virtually accepted the Republican contention, ruling that it could not go behind the returns except on the superficial issues of manifest fraud therein or the eligibility of electors to their office under the Constitution; that is, it could not investigate antecedents of fraud or misconduct of state officials in the results certified. All vital questions were settled by the electoral vote. In each of the seven Democratic states as the Republican Senate would never concur with the Democratic House in overriding the decisions, all the disputed votes were awarded to Mr. Hayes, who therefore was declared elected.

The strictly partisan votes of the commission and the adoption by prominent Democrats and Republicans, both within and without the commission, of an attitude toward states'-rights principles quite inconsistent with party tenets and tendencies, have given rise to much severe criticism. The Democrats and the country, however, quietly accepted the decision. The judgments underlying it were two: (1) That Congress rightly claimed the power to settle such contests within the limits set; (2) that, as Justice Miller said regarding these limits, the people had never at any time intended to give to Congress the power, by naming the electors, to "decide who are to be the president and vice-president of the United States."

The judgment that Mr. Tilden was morally entitled to the presidency, and the correction of the Louisiana frauds would certainly have given satisfaction then and increasing satisfaction later, in the retrospect, to the country. The commission might probably have corrected the frauds without exceeding its Congressional precedents. Nevertheless, the principles of its decisions must be recognized by all save ultra-nationalists as truer to the spirit of the Constitution and promising more for the good of the country than would have been the principles necessary to a contrary decision.

By an act of the 3rd of February 1887 the electoral procedure is regulated in great detail. Under this act determination by a state of electoral disputes is compulsory, subject to certain formalities that guarantee definite action and accurate certification. These formalities constitute "regularity," and are in all cases judgable by Congress. When Congress is forced by the lack of evident inconclusiveness of state action, or by conflicting state action, to decide disputes, votes are lost unless both houses concur.

The Law of the Electoral Count," and for the sources, Senate Miscellaneous Document No. 5 (vol. 1), and House Miscel. Doc. No. 13 (vol. 2), 44 Cong., 2 Sess.—Counsel of the Electoral Vote. Proceedings of Congress and Electoral Commission,—the latter identical with Congressional Record, vol. 5, p. 4, 44 Cong., 2 Sess; and about twenty volumes of evidence in the state election involved. The volume called The Presidential Counts (New York, 1877) was compiled by Mr Tilden and his secretary.

ELECTORS (Ger. Kurfürsten, from Kuren, O.H.G. kiusan, choose, elect, and Fürst, prince), a body of German princes, despotic in power, through the 15th century, and holding by the right of the German king, from the 13th until the beginning of the 19th century. The German kings, from the time of Henry the Fowler (919-936) till the middle of the 13th century, succeeded to their position partly by heredity, and partly by election. Primitive Germanic practice had emphasized the element of heredity. - Reges ex nobilitez rumunt: the man whom a German tribe recognized as its king must be in the line of hereditary descent from Woden; and therefore the genealogical trees of early Teutonic kings (as, for instance, in England those of the Kentish and West Saxon sovereigns) are carefully constructed to prove that descent from the god which alone will constitute a proper title for his descendents. Even from the first, however, there had been some opening for election; for the principle of primogeniture was not observed, and there might be several competing candidates, all of the true Woden stock. One of these competing candidates would have to be recognized (as the Anglo-Saxons said, gecosan); and to this limited extent Teutonic kings may be termed elective from the very first. In the other nations of western Europe this element of election dwindled, and the principle of heredity alone received legal recognition; in medieval Germany, on the contrary, the principle of heredity, while still exercising an inevitable natural force, sank formally into the background, and legal recognition was given only to the elective principle. De facto, therefore, the principle of heredity exercised in Germany, as elsewhere, an influence never more striking than in the period which follows on the formal recognition of the elective principle, when the Halsburgs (like the Metelli at Rome) fiant imperatores: de jure, each monarch owes his accession simply and solely to the vote of an electoral college.

This difference between the German monarchy and the other monarchies of western Europe may be explained by various considerations. Not the least important of these is what seems a pure accident. Whereas the Capetian monarchs, during the three hundred years that followed on the election of Hugh Capet in 987, always left an heir male, and an heir male of full age, the German kings again and again, during the same period, either left a minor to succeed to their throne, or left no issue at all. The principle of heredity began to fail because there were no heirs. Again the strength of tribal feeling in Germany made the monarchy into something which must be in the hands of any single tribe, but must circulate, as it were, from Franconian to Saxon, from Saxon to Bavarian, from Bavarian to Franconian, from Franconian to Swabian; while the growing power of the baronage, and its habit of erecting anti-kings to emphasize its opposition to the crown (as, for instance, in the reign of Henry IV.), coalesced with and gave new force to the action of tribal feeling. Lastly, the fact that the German kings were also Roman emperors finally and irretrievably consolidated the growing tendency towards the elective principle. The principle of heredity had never held any great sway under the ancient Roman Empire (see under Emperor); and the medieval Empire, instituted as it was by the papacy, came definitely under the influence of ecclesiastical prepossessions in favour of election. The church had substituted for that descent from Woden, which had elevated the old pagan kings to their thrones, the conception that the monarch derived his crown from the choice of God, after the manner of Saul; and the theoretical choice of God was readily turned into the actual choice of the church, or, at any rate, of the general body of churchmen. If an ordinary king is thus regarded by the church as essentially elected, much more will the emperor, connected as he is with the church as one of its officers, be held to be also elected; and as a bishop is chosen by the chapter of his diocese, so, it will be thought, must the emperor be chosen by some corresponding body in his empire. Heredity might be tolerated in a mere matter of kingship: the precious trust of imperial power could not be allowed to descend according to the accidents of family succession. To Otto of Freising (Gesta Frid. li. 1) it is already a point of right
ELECTORS

vindicated for itself by the excellency of the Romani Empire, as a matter of singular prerogative, that it should not descend per sanguinis propinquum, sed per principum eleccionem.

The election of Conrad II. (see Wipo, Vita Conradi, c. 1-2), of Lothair II. (see Narratio de eleccione Lotharii, M. G. II., Script. xii. p. 510), of Conrad III. (see Otto of Freising, Chronicon, vi. 22) and of Frederick I. (see Otto of Freising, Gesta Frid. ii. 1) had all been marked by an element, more or less pronounced, of election. That element is perhaps most considerable in the case of Lothair, who had no rights of heredity to urge. Here we read of ten princes being selected from the princes of the various duchies to whose choice the crown was to be offered, and of these ten selecting three candidates, one of whom, Lothair, is finally chosen (apparently by the whole assembly) in a somewhat tumultary fashion. In this case the electoral assembly would seem to be, in the last resort, the whole diet of all the princes. But a de facto pre-eminence in the act of election is already, during the 12th century, enjoyed by the three Rhenish archbishops, probably because of the part they afterwards played at the coronation, and also by the dukes of the great duchies—possibly because of the part they too played, as vesting for the time with the great officers of the household, at the coronation feast. Thus at the election of Lothair it is the archbishop of Mainz who conducts the proceedings; and the election is not held to be final until the duke of Bavaria has given his assent. The fact is that, voting being weighed by quality as well as by quantity (see Diet.), the votes of the archbishops and dukes, which would first be taken, would of themselves, if unanimous, determine the election. To prevent tumultuous elections, it was well that the election should be left exclusively with these great dignitaries; and this is what, by the middle of the 13th century, had eventually been done.

The chaos of the interregnum from 1198 to 1212 showed the way for the new departure; the chaos of the great interregnum (1230-1273) led to its being finally taken. The decay of the great duchies, and the narrowing of the class of princes into a close corporation, some of whose members were the equals of the old dukes in power, introduced difficulties and doubts into the practice of election which had been used in the 12th century. The contested election of the interregnum of 1198-1212 brought these difficulties and doubts into strong relief. The famous bull of Innocent III. (Venerabilium), in which he decided for Otto IV. against Philip of Swabia, on the ground that, though he had fewer votes than Philip, he had a majority of the votes of those ad quos principum electum, made it almost imperative that there should be some definition of these principal electors. The most famous attempt at such a definition is that of the Sachsenspiegel, which was followed, or combatté, by many other writers in the first half of the 13th century. Eventually the contested election of 1257 brought light and definition. Here we find seven potentes acting—the same seven whom the Golden Bull recognizes in 1356; and we find these seven described in an official letter to the pope, as principes regum in haereticis et electone habentes, qui sunt septem numeri. The doctrine thus enunciated was at once received. The pope acknowledged it in two bulls (1263); a cardinal, in a commentary on the bull Venerabilium of Innocent III., recognized it about the same time; and the erection of statues of the seven electors at Aix-la-Chapelle gave the doctrine a visible and outward expression.

By the election of Rudolph of Habsburg (1273) the seven electors may be regarded as a definite body, with an acknowledged right. But the definition and the acknowledgment were still imperfect. (1) The composition of the electoral body was uncertain in two respects. The duke of Bavaria claimed as his right the electoral vote of the king of Bohemia; and the practice of partitio in electoral families tended to raise further difficulties about the exercise of the vote. The Golden Bull of 1356 settled both these questions. Bohemia (of which Charles IV., the author of the Golden Bull, was himself the king) was assigned the electoral vote of the king of Bohemia; a provision annexing the electoral vote to a definite territory, declaring that territory indivisible, and regulating its descent by the rule of primogeniture instead of partition, swept away the old difficulties which the custom of partition had raised. After 1356 the seven electors are regularly the three Rhenish archbishops, Mainz, Cologne and Trier, and four lay magnates, the palatine of the Rhine, the duke of Saxony, the margrave of the Rhine, the king of Bohemia; the three former being vested with the three archchancellories, and the four latter with the four offices of the royal household (see Household). (2) The rights of the seven electors, in their collective capacity as an electoral college, were a matter of dispute with the papacy. The result of the election, whether made, as at first, by the princes generally or, as after 1257, by the seven electors exclusively, was in itself simply the creation of a German king—an electio in regem. But since 962 the German king was also, after coronation by the pope, Roman emperor. Therefore the election had a double result: the man elected was not only electus in regem, but also promovendus ad imperium. The difficulty was to define the meaning of the term promovendus. Was the king elect inevitably to become emperor? or did the promovendus only follow at the discretion of the pope, if he thought the king elect fit for promotion? and if so, to what extent, and according to what standard, did the pope judge of such fitness? Innocent III. had already taken up the matter; in the bull Venerabilium, (1) that the electors derived their power of election, so far as it made an emperor, from the Holy See (which had originally ‘translated’ the Empire from the East to the West), and (2) that the papacy had a jus et auctoritas examinandi personam electam in regem et promovendam ad imperium. The latter claim he had based on the fact that he anointed, consecrated and crowned the emperor—in other words, that he gave a spiritual office according to spiritual methods, which entitled him to inquire into the fitness of the recipient of that office, as a bishop inquires into the fitness of a candidate for ordination. Innocent had put forward this claim as a ground for deciding between competing candidates: Boniface VIII. pressed the claim against Albert I. in 1298, even though his election was unanimous; while John XXII. exercised it in its harshest form, when in 1324 he communicated Louis IV. for using the title and exercising the rights of a king without previous papal confirmation. This action ultimately led to a protest from the electors themselves, whose right of election would have become practically meaningless, if such assumptions had been tolerated. A meeting of the electors (Kurseisen) at Rense in 1338 declared (and the declaration was reaffirmed by a diet at Frankfort in the same year) that postquam aliquid eligitur in Imperatore sive Regem ad Electoribus Imperii concordari, vel majori parte concordari, statim ex sola electione est Rex terus et Imperator Romanus censorum: neque sine Sede Apostolica: approbatione: indiget. The doctrine thus positively affirmed at Rense is negatively reaffirmed in the Golden Bull, in which a significant silence is maintained in regard to papal rights. But the doctrine was not in practice followed: Sigismund himself did not venture to dispense with papal approbation.

By the end of the 14th century the position of the electors, both individually and as a corporate body, had become definite and precise. Individually, they were distinguished from all other princes, as we have seen, by the indivisibility of their territories and by the custom of primogeniture which secured that indivisibility; and they were still further distinguished by the fact that their person, like that of the emperor himself, was protected by the law of treason, while their territories were only subject to the jurisdiction of their own courts. They were independent territorial sovereigns; and their position was at once envied and that of the papacy.
as one of the seven, in his capacity of king of Bohemia, even at the expense of the Empire, and of himself in his capacity of emperor. For whatever the extinction of the imperial dignity in the person of the king, and the consequences of that loss, the power and influence of the emperor in the state of the empire, was not diminished by the loss of the imperial dignity.

1 See Schröder's "Lehrbuch der deutschen Rechtsgeschichte," p. 280. Finally, in 1728, the vote of Bavaria and the office of imperial butler returned to the counts palatine, as heirs of the duchy of Bavaria, in the person of John George, Elector Palatine. The vote for the Palatinate in 1648, with the office of imperial treasurer, was transferred to Brunswick-Lüneburg (Hanover) in lieu of the one which this house already held. In 1800, on the dissolution of the Holy Roman Empire, the electors ceased to exist.

ELETRA (ἐλέτρα), "the bright one," in Greek mythology.

(1) One of the seven Pleiades, daughter of Atlas and Pleione. She is closely connected with the old constellation worship and the religion of Samothrace, the chief seat of the Cabiri (q.v.), where she was generally supposed to dwell. By Zeus she was the mother of Dardanus, Iasion (or Etion), and Harmonia; but in the Italian tradition, which represented Italy as the original home of the Trojans, Dardanus was her son by a king of Italy named Corythus. After her amours with Zeus, Electra fled to the Palladium as a suppliant, but Athena, enraged that it had been touched by one who was no longer a maiden, flung Electra and the image from heaven to earth, where it was found by Ilius, and taken by him to Ilion; according to another tradition, Electra was driven to Samothrace by Hera, where she was killed by the ship's crew (Eurip. Phoen. 1156). In her grief at the destruction of the city she plucked out her hair and was changed into a comet; in another version Electra and her six sisters had been placed among the stars as the Pleiades, and the star which she represented lost its brilliancy after the fall of Troy. Electra's connexion with Samothrace (where she was also called Electryone and Strategis) is shown by the localisation of the carrying off of her reputed daughter Harmonia by Cadmus, and by the fact that, according to Athenia (the author of a work on Samothrace quoted by the scholiast on Apollonius Rhodius i. 917), the Cabiri were Dardanus and Iasion. The gate Electra at Thebes and the fabulous island Electria were said to have been called after her (Apollodorus iii. 10. 12; Servius on Aen. iii. 167, vii. 207, x. 272, Georg. i. 138).

(2) Daughter of Agamemnon and Clytaemnestra, sister of Orestes and Iphigenia. She does not appear in Homer, although according to Xanthus (regarded by some as a fictitious personage), to whom Stesichorus was indebted for much in his Orestes, she was identical with the Homeric Laodice, and was called Electra because she remained so long unmarried (Ἀλαξέρα). She was said to have played an important part in the poems of Stesichorus, and subsequently became a favourite figure in tragedy. After the murder of her father on his return from Troy by her mother and Aegisthus, she saved the life of her brother Orestes by sending him out of the country to Strophius, king of Phanote in Phocis, who had him brought up with his own son Pylades. Electra, cruelly ill-treated by Clytaemnestra and her paramour, never loses hope that her brother will return to avenge his father. When grown up, Orestes, in response to frequent messages from his sister, secretly repairs with Pylades to Argos, where he pretends to be a messenger from Strophius bringing the news of the death of Orestes. Being admitted to the palace, he slays both Aegisthus and Clytaemnestra. According to another story (Hyginus, Fab. 132), Electra, having received a false report that Orestes and Pylades had been sacrificed to Artemis in Tauris, went to consult the oracle at Delphi. In the meantime Aletes, the son of Aegisthus, seized the throne of Myceae. Her arrival at Delphi coincided with that of Orestes and Iphigenia. The same messenger, who had already communicated the false report of the death of Orestes, informed her that the lad was none other than Aletes by Iphigenia. Electra in her turn seized a burning brand from the altar, intending to blind her sister; but at the critical moment Orestes appeared, recognition took place, and the brother and sister returned to Myceae. Aletes was slain by Orestes, and
ELECTRICAL MACHINE

Electra became the wife of Pylades. The story of Electra is the subject of the Chōphoroi of Aeschylus, the Electra of Sophocles and the Electra of Euripides. It is in the Sophoclean play that Electra is most prominent.

There are many variations in the treatment of the legend, for which, as also for a discussion of the modern plays on the subject by Voltaire and Alberi, see Jebb's Introduction to his edition of the Electra of Sophocles.

ELECTRICAL (or ELECTROSTATIC) MACHINE, a machine operating by manual or other power for transforming mechanical work into electric energy in the form of electrostatical charges of opposite sign delivered to separate conductors. Electrostatic machines are of two kinds: (1) Frictional, and (2) Influence machines.

Frictional Machines.—A primitive form of frictional electrical machine was constructed about 1663 by Otto von Guericke (1602-1686). It consisted of a globe of sulphur fixed on an axis and rotated by a winch, and it was electrically excited by the friction of warm hands held against it. Sir Isaac Newton appears to have been the first to use a glass globe instead of sulphur (Optics, 8th Query). F. Hawksbee in 1709 also used a revolving glass globe. A metal chain resting on the globe served to collect the charge. Later G. M. Bose (1710-1761), of Wittenberg, added the prime conductor, an insulated tube or cylinder supported on silk strings, and J. H. Winkelr Closter (1703-1770), professor of physics at Leipzig, substituted a leather cushion for the hand. Andreas Gordon (1712-1784), a Benedictine monk, first used a glass cylinder in place of a sphere. Jesse Ramsden (1735-1800) in 1768 constructed his well-known form of plate electrical machine (fig. 1). A glass plate fixed to a wooden or metal shaft is rotated by a winch. It passes between two rubber made of leather, and is partly covered with two silk aprons which extend over quadrants of its surface. Just below the places where the aprons terminate, the glass is embraced by two insulated metal forks having the sharp points projecting towards the glass, but not quite touching it. The glass is excited positively by friction with the rubbers, and the charge is drawn off by the action of the points where, when acted upon inductively, discharge negative electricity against it. The insulated conductor to which the points are connected therefore becomes positively electrified. The cushions must be connected to earth to remove the negative electricity which accumulates on them. It was found that the machine acted better if the rubbers were covered with bisulphide of tin or with F. von Kienmayer's amalgam, consisting of one part of zinc, one of tin and two of mercury. The cushions were greased and the amalgam in a state of powder spread over them. Edward Nairne's electrical machine (1757) consisted of a glass cylinder with two insulated conductors, called prime conductors, on glass legs placed near it. One of these carried the leather exacting cushions and the other the collecting metal points, a silk apron extending over the cylinder from the cushion almost to the points. The rubber was smeared with amalgam. The function of the apron is to prevent the escape of electrification from the glass during its passage from the rubber to the collecting points. Nairne's machine could give either positive or negative electricity, the first named being collected from the prime conductor carrying the collecting points and the second from the prime conductor carrying the negative.

Influence Machines.—Frictional machines are, however, now quite superseded by the second class of instrument mentioned above, namely, influence machines. These operate by electrostatic induction and convert mechanical work into electrostatic energy by the aid of a small initial charge which is continually being replenished or reinforced. The general principle of all the machines described below will be best understood by considering a simple ideal case. Imagine two Leyden jars with large brass knobs, A and B, to stand on the ground (fig. 2). Let one jar be initially charged with positive electricity on its inner coating and the other with negative, and let both have their outsides connected to earth. Imagine two insulated balls A' and B' so held that A' is near A and B' is near B. Then the positive charge on A induces two charges on A', viz. a negative on the side nearest and a positive on the side most removed. Hence, however small the negative charge B' has induced on the side of B' nearest to it and repels negative electricity to the far side. Next let the balls A' and B' be connected together for a moment by a wire N called a neutralizing conductor which is subsequently removed. Then A' will be left negatively electrified and B' will be left positively electrified. Suppose that A' and B' are then made to change places. To do this we shall have to exert energy to remove A' against the attraction of B' and B' against the attraction of B. Finally let A' be brought in contact with B' and B' with A. The ball A' will give up its charge of negative electricity to the Leyden jar B, and the ball B' will give up its positive charge to the Leyden jar A. This transfer will take place because the inner coatings of the Leyden jars have greater capacity with respect to the earth than the balls. Hence the charges of the jars will be increased. The balls A' and B' are then practically discharged, and the above cycle of operations may be repeated. Hence, however small may be the initial charges of the Leyden jars, by a principle of accumulation resembling that of compound interest, they can be increased as above shown to any degree. If this series of operations be made to depend upon the continuous rotation of a winch or handle, the arrangement constitutes an electrostatic influence machine. The principle therefore somewhat resembles that of the self-exciting dynamo.

The first suggestion for a machine of the above kind seems to have grown out of the invention of Volta's electrophorus. Abraham Bennet, the inventor of the gold leaf electroscope, described a doubler or machine for multiplying electric charges (Phil. Trans., 1797).

The principle of this apparatus may be explained thus. Let A and C be two fixed disks, and B a disk which can be brought at will within a very short distance of either A or C. Let the capacitance of A be equal to p, and the coefficient of induction between A and B, or C and B, be c. Let us also suppose that the plates A and C are so distant from each other that there is no mutual influence, and that p' is the capacity of one of the disks when it stands alone. A small charge of electricity is communicated to A, and A is insulated, and B, uninsulated, is brought up to it; the charge on B will be $\frac{1}{p}Q$. B is now uninsulated and brought to face C, which is insulated: the charge on C will be $\frac{1}{p}Q^2$. C is now insulated and connected with A, which is always in a state of negative electricity. B is then brought to face A and uninsulated, so that the charge on A becomes $Q^2$, where $r = \frac{1}{p} + \frac{1}{c} = \frac{1}{p'}$, where A is now disconnected from C, and here the first operation ends. It is evident that at the end of $n$ such operations the charge on A will be $nQ^2$, so that the charge goes on increasing in geometrical progression. If the distance between the disks could be made.
infinite small each time, then the multiplier \( r \) would be \( 2 \), and the charge would be doubled each time. Hence the name of the apparatus.

Bennet's doubler appears to have given a suggestion to William Nicholson (Phil. Trans., 1788, p. 403) of "an instrument which by turning a winch produced the two states of electricity without friction or communication with the earth." This "revolving doubler," according to the description of Professor S. P. Thompson (loc. cit.), consists of two fixed plates of brass A and C (fig. 3), each two inches in diameter and separately supported on insulating arms in the same plane, so that a third revolving plate B may pass very near them without touching. A brass ball D two inches in diameter is fixed on the end of the axis that carries the plate B, and is loaded within one side, so as to act as a counterpoise to the revolving plate B. The axis P N is made of varnished glass, and so are the axes that join the three plates with the brass axis N O. The axis N O passes through the brass piece M, which stands on an insulating pillar of glass, and supports the plates A and C. At one extremity of this axis is the ball D, and the other is connected with a rod of glass, N P, upon which is fixed the handle L, and also the piece G H, which is separately insulated. The pins E, F rise back of the axis A and C, at unequal distances from the axis. The piece K is parallel to G H, and both of them are furnished at their ends with small pieces of flexible wire that they may touch the pins E, F in certain points of their revolution.

From the brass piece M there stands out a pin I, to touch against a small flexible wire or spring which projects sideways from the rotating plate B when it comes opposite A. The wires are so adjusted by bending that B, at the moment when it is opposite A, communicates with the ball D, and A communicates with C through G H; and half a revolution later, when B comes opposite to C, communicates with the ball D through the contact of K with F. In all other positions A, B, C, and D are completely disconnected from each other. Nicholson thus described the operation of his machine:

"When the plates A and B are opposite each other, the two fixed plates A and C may be considered as one mass, and the revolving plate B, together with the ball D, will constitute another mass. All the experiments yet made concur to prove that these two masses will not possess the same electric state. The redundant electricity in the masses under consideration will be equally distributed; the plate A will have about ninety-nine parts, and the plate C one; and, for the same reason, the revolving plate B will have ninety-nine parts of the opposite electricity, and the ball D one. The rotation, by destroying the contacts, preserves this unequal distribution, and carries B from A to C at the same time that the tail K connects the ball with the plate C. In this situation, the electricity in B acts upon that in C, and produces the contrary state, by virtue of the communication between B and C and the ball; which last must therefore acquire an electricity of the same kind with that of the revolving plate. But the rotation again destroys the contact and restores B to its first situation opposite A. Here, therefore, to the effect of the whole revolution, we shall find that the electric states of the respective masses have been greatly increased; for the mass of the fixed B and C remain, and the one part of electricity in C has been increased so as nearly to compensate ninety-nine parts of the opposite electricity in the revolving plate B, while the communication produced an opposite mutation in the electricity of the ball. A second rotation will, of course, produce a proportional augmentation of these increased quantities; and a continuance of turning will soon bring the intensities to their maximum, which is limited by an explosion between the plates" (Phil. Trans., 1788, p. 405).

Nicholson described also another apparatus, the "spinning doubler," which worked on the same principle. Bennet and Nicholson were followed by T. Cavallo, John Read, Bohnenberger, C. B. Desormes and J. N. P. Hachette and others in the invention of various forms of rotating doubler. A simple and typical form of doubler, devised in 1831 by G. Belli (fig. 4), consisted of two curved metal plates between which revolved a pair of balls carried on an insulating stem. Following the nomenclature usual in connection with dynamos we may speak of the conductors which carry the initial charges as the field plates, and of the moving conductors on which are induced the charges which are subsequently added to those on the field plates, as the carriers. The wire which connects two armature plates for a moment is the neutralizing conductor. The two curved metal plates constitute the field plates and must have original charges imparted to them of opposite sign. The rotating balls are the carriers, and are connected together for a moment by a wire when in a position to be acted upon inductively by the field plates, thus acquiring charges of opposite sign. The moment after they are separated again. The rotation continuing the ball thus negatively charged is made to give up this charge to that negatively electrified field plate, and the ball positively charged its charge to the positively electrified field plate, by touching little contact springs. In this manner the field plates accumulate charges of opposite sign.

Modern types of influence machine may be said to date from 1860 when C. F. Varley patented a type of influence machine which has been the parent of numerous subsequent forms (Brit. Pat. Spec. No. 206 of 1860). In it the field plates were sheets of tin-foil attached to a glass plate (fig. 5). In front of them a disk of ebonite or glass, having carriers of metal fixed to its edge, was rotated by a winch. In the course of their rotation two diametrically opposite carriers moved against the ends of a neutralizing conductor so as to form for a moment one conductor, and the moment afterwards these two carriers were insulated, one carrying away a positive charge and the other a negative. Continuing their rotation, the positively charged carrier gave up its positive charge by touching a little knob attached to the positive field plate, and similarly for the negative charge carrier. In this way the charges on the field plates were continually replenished and reinforced. Varley also constructed a multiple form of influence machine having six rotating disks, each having a number of carriers and rotating between field plates. With this apparatus he obtained sparks 6 in. long, the initial source of electrification being a single Daniell cell.

Varley was followed by A. J. I. Toepfer, who in 1865 constructed an influence machine consisting of two disks fixed on the same shaft and rotating in the same direction. Each disk carried two strips of tin-foil extending nearly over a semi-circle, and there were two field plates, one behind each disk; one of the plates was positively and the other negatively electrified. The carriers which were touched under the influence of the positive field plate passed on and gave up a portion of their negative charge to increase that of the negative field plate; in the same
way the carriers which were touched under the influence of the negative field plate sent a part of their charge to augment that of the positive field plate. In this apparatus one of the charging rods communicated with one of the field plates, but the other with the neutralizing brush opposite to the other field plate. Hence one of the field plates would always remain charged when a spark was taken at the transmitting terminals.

Between 1864 and 1880, W. T. B. Holtz constructed and described a large number of influence machines which were for a long time considered the most advanced development of this type of electrostatic machine. In one form the Holtz machine consisted of a glass disk mounted on a horizontal axis F (fig. 6) which could be made to rotate at a considerable speed by a multiplying gear, part of which is seen at

Fig. 6.—Holtz’s Machine.

X. Close behind this disk was fixed another vertical disk of glass in which were cut two windows B, B. On the side of the fixed disk next the rotating disk were pasted two sectors of paper A, A, with short blunt points attached to them which projected out into the windows on the side away from the rotating disk. On the other side of the rotating disk were placed two metal combs C, C, which consisted of sharp points set in metal rods and were each connected to one of a pair of discharge balls E, D, the distance between which could be varied. To start the machine the balls were brought in contact, one of the paper armatures electrified, say, with positive electricity, and the disk set in motion. Thereupon very shortly a hissing sound was heard and the machine became harder to turn as if the disk were moving through a resisting medium. After that the discharge balls might be separated a little and a continuous series of sparks or brush discharges would take place between them. If two Leyden jars L, L were hung upon the conductors which supported the combs, with their outer coatings put in connexion with one another by M, a series of strong spark discharges passed between the discharge balls. The action of the machine is as follows: Suppose one paper armature to be charged positively, it acts by induction on the right hand comb, causing negative electricity to issue from the comb points upon the glass revolving disk; at the same time the positive electricity passes through the closed discharge circuit to the left comb and issues from its teeth upon the part of the glass disk at the opposite end of the diameter. This positive electricity electrifies the left paper armature by induction, positive electricity issuing from the blunt point upon the side farthest from the rotating disk. The charges thus deposited on the glass disk are carried round so that the upper half is electrified negatively on both sides and the lower half positively on both sides, the sign of the electrification being reversed as the disk passes between the combs and the armature by discharges issuing from them respectively. If it were not for leakage in various ways, the electrification would go on everywhere increasing, but in practice a stationary state is soon attained. Holtz’s machine is very uncertain in its action in a moist climate, and has generally to be enclosed in a chamber in which the air is kept artificially dry.

Robert Voss, a Berlin instrument maker, in 1880 devised a form of machine in which he claimed that the principles of Toepler and Holtz were combined. On a rotating glass or ebonite disk were placed carriers of tin-foil or metal buttons against which neutralizing brushes touched. This armature plate revolved in front of a field plate carrying two pieces of tin-foil backed up by larger pieces of varnished paper. The studs on the armature plate were charged inductively by being connected for a moment by a neutralizing wire as they passed in front of the field plates, and then gave up their charges partly to renew the field charges and partly to collecting combs connected to discharge balls. In general design and construction, the manner of moving the rotating plate and in the use of the two Leyden jars in connexion with the discharge balls, Voss borrowed his ideas from Holtz.

All the above described machines, however, have been thrown into the shade by the invention of a greatly improved type of influence machine first constructed by James Wimshurst about 1878. Two glass disks are mounted on two shafts in such a manner that, by means of two belts and pulleys worked from a winch shaft, the disks can be rotated rapidly in opposite directions close to each other (fig. 7). These glass disks carry on them a certain number (not less than 16 or 20) tin-foil carriers which may or may not have brass buttons upon them. The glass plates are well varnished, and the carriers are placed on the outer sides of the two glass plates. As therefore the disks revolve, these carriers travel in opposite directions, coming at intervals in opposition to each other. Each upright bearing carrying the shafts of the revolving disks also carries a neutralizing conductor or wire ending in a little brush of gilt thread. The neutralizing conductors for each disk are placed at right angles to each other. In addition there are collecting combs which occupy an intermediate position and have sharp points projecting inwards, and coming near to but not touching the carriers. These combs on opposite sides are connected respectively to the inner coatings of two Leyden jars whose outer coatings are in connexion with one another.

The operation of the machine is as follows: Let us suppose that one of the studs on the back plate is positively electrified and one at the opposite end of a diameter is negatively electrified, and that at that moment two corresponding studs on the front plate passing opposite to these back studs are momentarily connected together by the neutralizing wire belonging to the front plate. The positive stud on the back plate will act inductively on the front stud and charge it negatively, and similarly for the other stud, and as the rotation continues these charged studs will pass round and give up most of their charge through the combs to the Leyden jars. The moment, however, a pair of studs on the front plate are charged, they act as field plates to studs on the back plate which are passing at the moment, provided these last are connected by the back neutralizing wire. After a few revolutions of the disks half the studs on the front plate at any moment are charged negatively and half positively and the same on the back plate, the neutralizing wires forming the boundary between the positively and negatively charged studs. The diagram in fig. 8, taken by permission from S. P. Thompson’s paper (loc. cit.), represents a view of the distribution of these charges on the front and back plates respectively. It will be
seen that each stud is in turn both a field plate and a carrier having a charge induced on it, and then passing on in turn induces further charges on other studs. Wimshurst constructed numerous very powerful machines of this type, some of them with multiple plates, which operate in almost any climate, and rarely fail to charge themselves by delivering a torrent of sparks between the discharge plates whenever the winch is turned. He also devised an alternating current electrical machine in which the discharge plates were alternately positive and negative. Large Wimshurst multiple plate influence machines are often used instead of induction coils for exciting Röntgen ray tubes in medical steady illumination on fluorescent screens.

In 1900 it was found by F. Tudshury that if an influence machine is enclosed in a metallic chamber containing compressed air, or better, carbon dioxide, the insulating properties of compressed gases enable a greatly improved effect to be obtained owing to the diminution of the leakage across the plates and from the supports. Hence sparks can be obtained of more than double the length at ordinary atmospheric pressure. In one case a machine with plates 8 in. in diameter which could give sparks 5.5 in. at ordinary pressure gave sparks of 5, 7, and 8 in. as the pressure was raised to 15, 30, and 45 lb above the normal atmosphere.

The action of Lord Kelvin's replenisher (fig. 9) used by him in connexion with his electrometers for maintaining their charge, closely resembles that of Bell's doubler and will be understood from fig. 9. Lord Kelvin also devised an influence machine, commonly called a "mouse mill," for electrifying the ink in connexion with his siphon recorder. It was an electrostatic and electromagnetic machine combined, driven by an electric current and producing in turn electrostatic charges of electricity.

**ELECTRIC EEL—ELECTRICITY**

**ELECTRIC EEL (Gymnotus electricus)**, a member of the family of fishes known as Gymnotidae. In spite of their external similarity the Gymnotidae have nothing to do with the eels (Anguillidae). They resemble the latter in the elongation of the body, the large number of vertebrae (240 in Gymnotus), and the absence of pelvic fins; but they differ in all the more important characters of internal structure. They are in fact allied to the carps or Cyprinidae and the cat-fishes or Siluridae. In common with these two families and the Characidae of Africa and South America, the Gymnotidae possess the peculiar structures called *ossicula auditus* or Weberian ossicles. These are a chain of small bones belonging to the first four vertebrae, which are much modified, and connecting the air-bladder with the auditory organs. Such an agreement in the structure of so complicated and specialized an apparatus can only be the result of a common descent of the families possessing it. Accordingly these families are now placed together in a distinct sub-order, the Ostariophysi. The Gymnotidae are strongly modified and degraded Characidae. In them the dorsal and caudal fins are very rudimentary or absent, and the anal is very long, extending from the anus, which is under the head or throat, to the end of the body.

Gymnotus is the only genus of the family which possesses electric organs. These extend the whole length of the tail, which is five-fifths of the body. They are modifications of the lateral muscles and are supplied with numerous branches of the spinal nerves. They consist of longitudinal columns, each composed of an immense number of "electric plates." The posterior end of the organ is positive, the anterior negative, and the current passes from the tail to the head. The maximum shock is given when the head and tail of the Gymnotus are in contact with different points in the surface of some other animal. Gymnotus electricus attains a length of 3 ft. and the thickness of a man's thigh, and frequents the marshes of Brazil and the Guianas, where it is regarded with terror, owing to the formidable electrical apparatus with which it is provided. When this natural battery is discharged in a favourable position, it is sufficiently powerful to stun the largest animal; and according to A. von Humboldt, it has been found necessary to change the lines of certain roads passing through the pools frequented by the electric eels. These fish are eaten by the Indians, who, before attempting to capture them, seek to exhaust their electrical power by driving horses into the ponds. By repeated discharges upon these they gradually expend this marvellous force; after which, being defenceless, they become timid, and approach the edge for shelter, when they fall an easy prey to the harpoon. It is only after long rest and abundance of food that the fish is able to resume the use of its subtle weapon. Humboldt's description of this method of capturing the fish has not, however, been verified by recent travellers.

**ELECTRICITY.** This article is devoted to a general sketch of the history of the development of electrical knowledge on both the theoretical and the practical sides. The two great branches of electrical theory which concern the phenomena of electricity are the electrostatic and the electric current or "electric" electricity. "Electric" electricity, when in motion, or electric currents, are treated in two separate articles, Electrostatics and Electrodynamics. The phenomena attendant on the passage of electricity through solids, through liquids and through gases, are described in the article Conductance, Electric, and also Electrolysis, and the propagation of electrical vibrations in Electric Waves. The interconnexion of magnetism (which has an article to itself) and
electricity is discussed in Electromagnetism, and these manifestations in nature in Atmospheric Electricity; Aurora Polaris and Magnetism, Terrestrial. The general principles of electrical engineering will be found in Electricity Supply, and further details respecting the generation and use of electrical power are given in such articles as Dynamo; Motors; Electric; Transformers; Accumulator; Power Transmission; Electric; Tramton; Lighting; Electric; Electrochemistry and Electrometallurgy. The principles of telegraphy (land, submarine and wireless) and of telephony are discussed in the articles Telegraph and Telephone, and various electrical instruments are treated in separate articles such as Amperemeter; Electrometer; Galvanometer; Voltmeter; Wheatstone's Bridge; Potentiometer; Meter; Electric; Electrophorus; Leyden Jar; &c.

The term "electricity" is applied to denote the physical agency which exhibits itself by effects of attraction and repulsion when particular substances are rubbed or heated, also in certain chemical and physiological actions and in connexion with moving magnets and metallic circuits. The name is derived from the word electrifica, first used by William Gilbert (1544-1603) in his epoch-making treatise De magnete, magnetisque corporibus, &c. de causis, potentiarum, &c. published in 1600. 1 to denote substances which possess a similar property to amber (= elektris), from ἐλεκτρόνον of attracting light objects when rubbed. Hence the phenomena came to be collectively called electrical, a term first used by William Barlowe, archdeacon of Salisbury, in 1618, and the study of them, electrical science. Historical Sketch.

Gilbert was the first to conduct systematic scientific experiments on electrical phenomena. Prior to his date the scanty knowledge possessed by the ancients and enjoyed in the middle ages began and ended with facts said to have been familiar to Thales of Miletus (600 B.C.) and mentioned by Theophrastus (321 B.C.) and Pliny (A.D. 70), namely, that amber, jet and one or two other substances possessed the power, when rubbed, of attracting fragments of straw, leaves or feathers. Starting with careful and accurate observations on facts concerning the mysterious properties of amber and the lodestone, Gilbert laid the foundations of modern electric and magnetic science on the true experimental and inductive basis. The subsequent history of electricity may be divided into four well-marked periods. The first extends from the date of publication of Gilbert's great treatise in 1600 to the invention by Volta of the voltaic pile and the first production of the electric current in 1799. The second dates from Volta's discovery to the year 1831, the period of the induction of electric currents and the creation of currents by the motion of conductors in magnetic fields, which initiated the era of modern electrotechnics. The third covers the period between 1831 and Clerk Maxwell's enunciation of the electromagnetic theory of light in 1865 and the invention of the self-exciting dynamo, which marks another great epoch in the development of the subject; and the fourth comprises the modern development of electric theory and of absolute quantitative measurements, and above all, of the applications of this knowledge in electrical engineering. We shall sketch briefly the historical progress during these various stages, and also the growth of electrical theories of electricity during that time.

First Period.—Gilbert was probably led to study the phenomena of the attraction of iron by the lodestone in consequence of his conversion to the Copernican theory of the earth's motion, and thence proceeded to study the attractions produced by amber. An account of his electrical discoveries is given in the De magnete, lib. ii. cap. 2. 2 He invented the versorium or electrical needle and proved that innumerable bodies he called electric, when rubbed, can attract the needle of the versorium (see Electroscope). Robert Boyle added many new facts and gave an account of them in his book, The Origin of Electricity. He showed that the attraction between the rubbed body and the test object is mutual. One view has it that Gilbert constructed the first electrical machine with a revolving ball of sulphur (see Electrical Machine), and noticed that light objects were repelled after being attracted by excited electricity. Sir Isaac Newton substituted a ball of glass for sulphur in the electrical machine and made other not unimportant additions to electrical knowledge. Francis Hawksbee (d. 1713) published in his book Physico-Mechanical Experiments (1709), and in several Memoirs in the Phil. Trans. about 1709, the results of his electrical inquiries. He showed that light was produced when mercury was shaken up in a glass tube exhausted of its air. Dr Wall observed the spark and crackling sound when warm amber was rubbed, and compared them with thunder and lightning (Phil. Trans., 1708, 26, p. 69). Stephen Gray (1666-1736) noticed in 1720 that electricity could be excited by the friction of hair, silk, wool, paper and other bodies. In 1729 Gray made the important discovery that some bodies were conductors and others non-conductors of electricity. A year later, in 1730, Volta, the former professor at Padua, published the discovery that a battery of 60 sheets of silver was a conductor of electricity. He then prepared two kinds of conductors, those of iron, wood, brass, copper and slate, and others of glass, crystal, and cork, &c. He went on to make observations of the effects of electric discharges in glass, crystal, &c. and found that glass, crystal, &c. were rubbed with silk, and the second when resin, amber, silk or paper, &c. are excited by friction with flannel. He also discovered that a body charged with positive or negative electricity repels a body free to move when the latter is charged with electricity of like sign, but attracts it if it is charged with electricity of opposite sign, i.e. positive repels positive and negative repels negative, but positive attracts negative. It is to du Fay also that we owe the abolition of the distinction between electricity and non-electrics. He showed that all substances could be electrified by friction, but that to electrify conductors they must be insulated or supported on non-conductors. Various improvements were made in the electrical machine, and thereby experimentalists were provided with the means of generating strong electricity; C. F. Ludoff (1707-1763) of Berlin in 1744 succeeded in igniting ether with electric spark. The discovery of the Leyden jar in 1745 by F. Thomson (1744, 43, p. 167).

For a very full list of the papers and works of the early electrical philosophers, the reader is referred to the bibliography on Electricity in Dr Thomas Young's Natural Philosophy, vol. ii. p. 415.

In 1745 the important invention of the Leyden jar or condenser was made by E. G. von Kleist of Kammin, and almost simultaneously by Cunaeus and Pieter van Musschenbroek (1692-1761) of Leiden (see Leyden Jar). Sir William Watson (1713-1787) in England first observed the flash of light when a Leyden jar is discharged, and he and Dr John Bevis (1665-1721) suggested coating the jar inside and outside with tinfoil. Watson carried out elaborate experiments to discover how far the electric discharge of the jar could be conveyed along metallic wires and was able to accomplish it for a distance of 2 m., making the important observation that the electricity appeared to be transmitted instantaneously.

In Franklin's Researches, Benjamin Franklin (1706-1790) was one of the great pioneers of electrical science, and made the ever memorable experimental identification of lightning and electric spark. He argued that electricity is not created by friction, but merely collected from its state of diffusion through other matter by which it is attracted. He asserted that the glass globe, when rubbed, attracted the electrical fire, and took it from the rubber, the same globe being disposed, when the friction ceases, to give out its electricity to any body which has less. In the case of the charged Leyden jar, he asserted that the inner coating of tinfoil
ELECTRICITY

had received more than its ordinary quantity of electricity, and was therefore electrified positively, or plus, while the outer coating of tinfoil having had its ordinary quantity of electricity diminished, was electrified negatively, or minus. Hence the cause of the shock and spark when the jar is discharged, or when the superabundant or plus electricity of the inside is transferred by a conducting body to the defective or minus electricity of the outside. This theory of the Leyden phial Franklin supported very ingeniously by showing that the outside and the inside coating possessed electricities of opposite sign, and that, in charging it, exactly as much electricity is added on one side as is subtracted from the other. The abundant discharge of electricity by points was observed by Franklin is his earliest experiments, and also the power of points to conduct it copiously from an electrified body. Hence he was furnished with a simple method of collecting electricity from other bodies, and he was enabled to perform those remarkable experiments which are chiefly connected with his name. Hawksee, Wall and J. A. Nollet (1700-1770) had successively suggested the identity of lightning and the electric spark, and of thunder and the snap of the spark. (Previously to the year 1750, Franklin drew up a statement, in which he showed that all the general phenomena and effects which were produced by electricity had their counterparts in lightning. After waiting some time for the erection of a spire at Philadelphia, by means of which he hoped to bring down the electricity of a thunderstorm, he conceived the idea of sending up a kite among thunder-clouds. With this view he made a small cross of two small light strips of cedar, the arms being sufficiently long to reach to the four corners of a large thin silk handkerchief when extended. The corners of the handkerchief were tied to the extremities of the cross, and when the body of the kite was thus formed, a tail, loop and string were added to it. The body was made of silk to enable it to bear the violence and wet of a thunderstorm. A very sharp pointed wire was fixed at the top of the upright stick of the cross, so as to rise a foot or more above the wood. A silk ribbon was tied to the end of the twine next the hand, and a key suspended at the junction of the twine and silk. In company with his son, Franklin raised the kite like a common one, in the first thunderstorm, which happened in the month of June 1752. To keep the silk ribbon dry, he stood within a door, taking care that the twine did not touch the frame of the door; and when the thunder-clouds came over the kite he watched the state of the string. A cloud passed without any electrical indications, and he began to despair of success. At last, however, he saw the loose filaments of the twine standing out every way, and he found them to be attracted by the approach of his finger. The suspended key gave a spark on the approach of his knuckle, and the twine and silk were raised with the rain the electricity became abundant. A Leyden jar was charged at the key, and by the electric fire thus obtained spirits were inflamed, and many other experiments performed which had been formerly made by excited electrics. In subsequent trials with another apparatus, he found that the clouds were sometimes positively and sometimes negatively electrified, and so demonstrated the perfect identity of lightning and electricity. Having thus succeeded in drawing the electric fire from the clouds, Franklin conceived the idea of protecting buildings from lightning by erecting on their highest parts pointed iron wires or conductors communicating with the ground. The electricity of a hovering or a passing cloud thus might be carried off slowly and silently; and if the cloud was highly charged, the lightning would strike in preference the elevated conductors.

The experiment in America, T. F. Dalibard (1703-1779) and others in France had erected a long iron rod at Marli, and obtained results agreeing with those of Franklin. Similar investigations were pursued by many others, among whom Father G. B. Beccaria (1716-1781) deserves especial mention. John Canton (1718-1772) made the important contribution to knowledge that electricity of either sign could be produced on nearly any body by friction with appropriate substances, and that a rod of glass roughened on one half was excited negatively in the rough part and positively in the smooth part by friction with the same rubber. Canton first suggested the use of an amalgam of mercury and tin for use with glass cylinder electrical machines to improve their action. His most important discovery, however, was that of electrostatic induction, the fact that one electrified body can produce charges of electricity upon another insulated body, and that when this last is touched it is left electrified with a charge of opposite sign to that of the inducing charge (Phil. Trans., 1753-1754). We shall make mention lower down of Canton's contributions to electrical theory. Robert Symmer (d. 1763) showed that quite small differences determined the sign of the electrification that was generated by the friction of two bodies one against the other. Thus wearing a black and a white silk stocking one over the other, he found they were electrified oppositely when rubbed and then drawn off, and such a rubbed silk stocking when deposited in a Leyden jar gave up its electrification to the jar (Phil. Trans., 1759). Ebenezer Kinnersley (1711-1778) of Philadelphia made useful observations on the elongation and fusion of iron wires by electrical discharges (Phil. Trans., 1763). A contemporary of Canton and co-discoverer with him of the facts of electrostatic induction was the Swede, Johann Karl Wilcke (1732-1790), then resident in Germany, who in 1762 published an account of experiments in which a metal plate below the upper surface of a glass table was subjected to the action of a charge on an electrified metal plate held below the glass (Kon. Schwedische Akad. Abhandl., 1762, 24, p. 213).

Pyrro-electricity.—The subject of pyro-electricity, or the power possessed by some minerals of becoming electrified when merely heated, and of exhibiting positive and negative electricity, now began to attract notice. It is possible that the lyncurium of the ancients, which according to Theophrastus attracted light bodies, was tourmaline, a mineral found in Ceylon, which had been christened by the Dutch with the name of aschenstikker, or the attractor of ashes. In 1717 Louis Lémery exhibited to the Paris Academy of Sciences a stone from Ceylon which attracted light bodies; and Linnaeus in mentioning his experiments gives the stone the name of lapis electricus. Giovanni Caraffa, duca di Nuja (1715-1768), was led in 1758 to purchase some of the stones called tourmaline in Holland, and, assisted by L. J. M. Daubenton and Michel Adanson, he made experiments with them, a description of which he gave in a letter to G. L. L. Buffon in 1759. The subject, however, had already engaged the attention of the German philosopher, F. U. T. Aepinus, who published an account of them in 1756. Hitherto nothing had been said respecting the necessity of heat to excite the tourmaline; but it was shown by Aepinus that a temperature between 99° and 212° Fahr. was requisite for the development of its attractive properties. Benjamin Wilson (Trans., 1763, &c.), J. Priestley, and Canton continued the investigation, but it was reserved for the Abbé Haüy to throw a clear light on this curious branch of the science (Traité de minéralogie, 1801). He found that the electricity of the tourmaline decreased rapidly from the summits or poles towards the middle of the crystal, where it was imperceptible; and he discovered that if a tourmaline is broken into any number of fragments, each fragment, when excited, has two opposite poles. He observed that the Siberian and Brazilian topaz, borate of magnesia, mesotephy, prehnite, sphene and calamine. He also found that the polarity which minerals receive from heat has a relation to the secondary forms of their crystals—the tourmaline, for example, having its resinous pole at the summit of the crystal which has three faces. In the other pyro-electric crystals above mentioned, Haüy detected the same deviation from the rules of symmetry.
in their secondary crystals which occurs in tourmaline. C. P. Brard (1788–1838) discovered that pyro-electricity was a property of azinite; and it was afterwards detected in other minerals. In repeating and extending the experiments of Hatty much later, Sir David Brewster discovered that various artificial salts were pyro-electric, and he mentions the tartrates of potassium and calcium as exhibiting this property nearly to a very strong degree. He also made many experiments with the tourmaline when cut into thin slices, and reduced to the finest powder, in which state each particle preserved its pyro-electricity; and he showed that scelezite and moseelite, even when deprived of their water of crystallization and reduced to powder, retain their property of becoming electrical by heat. When this white powder is heated and stirred about by any substance whatever, it collects in masses like newly-fallen snow, and adheres to the body with which it is stirred.

For Sir David Brewster's work on pyro-electricity, see Trans. Roy. Soc. Edin., 1845, also Phil. Mag., Dec., 1847. The reader will also find a full discussion on the subject in the Tracts on Electricity, by A. de la Rive, translated by C. V. Walker (London, 1856), vol. ii., part v. ch. i.

Animal electricity.—The observation that certain animals could give shocks resembling the shock of a Leyden jar induced a closer examination of these powers. The ancients were acquainted with the bemuning power of the torpedo-fish, but it was not till 1676 that modern naturalists had their attention again drawn to the fact. E. Bancroft was the first person who distinctly suspected that the effects of the torpedo were electrical. In 1773 John Walsh (d. 1792) and Jan Ingenhouz (1730–1799) proved by many curious experiments that the shock of the torpedo was an electrical one (Phil. Trans., 1773–1773); and John Hunter (id. 1773, 1775) examined and described the anatomical structure of its electrical organs. A. von Humboldt and Gay-Lussac (Ann. Chim., 1803), and Etienne Geoffroy Saint-Hilaire (G. Ann., 1803) pursued the subject with success, and Henry Cavendish (Phil. Trans., 1776) constructed an artificial torpedo, by which he imitated the actions of the living animal. The subject was also investigated (Phil. Trans., 1812, 1817) by Dr T. J. Todd (1789–1840), Sir Humphry Davy (id. 1820), John Davy (id. 1832, 1834, 1841) and Faraday (Exp. Res., vol. ii.). The power of giving electric shocks has been discovered also in the Gymnotus electricus (electric eel), the Malpissirius electricus, and the Tripanodon electricus. The most interesting and the best known of these singular fishes is the Gymnotus or Surinam eel. Humboldt gives a very graphic account of the combats which are carried on in South America between the gymnoti and the wild horses in the vicinity of Calabozo.

Cavendish's Researches.—The work of Henry Cavendish (1731–1810) entitles him to a high place in the list of electrical investigators. A considerable part of Cavendish's work was rescued from oblivion in 1789 and placed in an easily accessible form by Professor Clark Maxwell, who edited the original manuscripts in the possession of the duke of Devonshire. Amongst Cavendish's important contributions were his exact measurements of electrical capacity. The leading idea which distinguishes his work from that of his predecessors was his use of the phrase "degree of electrification" with a clear scientific definition which shows it to be equivalent in meaning to the modern term "electrical potential." Cavendish compared the capacity of different bodies with those of conducting spheres of known diameter and states these capacities in "globular inches," a globular inch being the capacity of a sphere 1 in. in diameter. Hence his measurements are all directly comparable with modern electrostatic measurements in which the unit of capacity is that of a sphere 1 centimetre in radius. Cavendish measured the capacity of disks and condensers of various forms, and proved that the capacity of a Leyden jar is proportional to the surface of the tinfoil and inversely as the thickness of the glass. In connexion with this subject he anticipated one of Faraday's greatest discoveries, namely, the effect of the dielectric or insulator upon the capacity of a condenser formed with it, in other words, made the discovery of specific inductive capacity (see Electrical Researches, p. 183). He made many measurements of the electric conductivity of various solids and liquids, by electric shocks of low intensity exhibiting this property to a very strong degree. He also made many experiments with the tourmaline when cut into thin slices, and reduced to the finest powder, in which state each particle preserved its pyro-electricity; and he showed that scelezite and moseelite, even when deprived of their water of crystallization and reduced to powder, retain their property of becoming electrical by heat. When this white powder is heated and stirred about by any substance whatever, it collects in masses like newly-fallen snow, and adheres to the body with which it is stirred.

Coulomb's Work.—Contemporary with Cavendish was C. A. Coulomb (1736–1806), who in France addressed himself to the same kind of exact quantitative work as Cavendish in England. Coulomb has made his name for ever famous by his invention and application of his torsion balance to the experimental determination of the fundamental law of electric attraction in which, however, he was anticipated by Cavendish, namely, that the force of attraction between two small electrified spherical bodies varies as the product of their charges and inversely as the square of the distance of their centres. Coulomb's work received better publication than Cavendish's at the time of its accomplishment, and, provided a basis on which mathematicians could operate. Accordingly the close of the 18th century drew into the arena of electrical investigation on its mathematical side P. S. Laplace, J. B. Biot, and above all, S. D. Poisson. Adopting the hypothesis of two fluids, Coulomb investigated experimentally and theoretically the distribution of electricity on the surface of bodies by means of his proof plane. He determined the law of distribution between two conducting bodies in contact; and measured with his proof plane the density of the electricity at different points of two spheres in contact, and enunciated his fundamental law. He ascertained the distribution of electricity among several spheres (whether equal or unequal) placed in contact in a straight line; and he measured the distribution of...
ELECTRICITY

electricity on the surface of a cylinder, and its distribution between a sphere and cylinder of different lengths but of the same diameter. His experiments on the dissipation of the electric potential also contributed to this, that the momentary dissipation was proportional to the degree of electrification at the time, and that, when the charge was moderate, its dissipation was not altered in bodies of different kinds or shapes. The temperature and pressure of the atmosphere did not produce any sensible change; but he concluded that the dissipation was nearly proportional to the cube of the quantity of moisture in the air. In examining the dissipation which takes place along imperfectly insulating substances, he found that a thread of gum-lac was the most perfect of all insulators; that it insulated ten times as well as a dry silk thread; and that a silk thread covered with fine sealing-wax insulated as powerfully as gum-lac when it had four times its length. He found also that the dissipation of electricity along insulators was chiefly owing to adhering moisture, but in some measure also to a slight conducting power. For his memoirs see *Mém. de math. et phys. de l'acad. de sc., 1785, 6th.

SECOND PERIOD.—We now enter upon the second period of electrical research inaugurated by the epoch-making discovery of Alessandro Volta (1745–1827). L. Galvani had made in 1790 his historic observations on the muscular contraction produced in the bodies of recently killed frogs when an electrical machine was being worked in the same room, and described them in 1792 (De viribus electricitatis in motu musculari commensuratis, Bologna, 1792). Volta followed up these observations with rare philosophic insight and experimental skill. He showed that all conductors liquid and solid might be divided into two classes which he called respectively conductors of the first and of the second class, the first embracing metals and carbon in its conducting form, and the second class, water, aqueous solutions of various kinds, and generally those now called electrotypes. In the case of conductors of the first class he proved by the use of the condensing electroscope, aided probably by some form of multiplier or doubler, that a difference of potential (see electrostatics) was created by the mere contact of two such conductors, one of them being positively electrified and the other negatively. Volta showed, however, that if a series of bodies of the first class, such as disks of various metals, are placed in contact, the potential difference between the first and the last is just the same as if they are immediately in contact. There is no accumulation of potential. If, however, pairs of metallic disks of zinc and copper or alternated foils of cloth wetted with a conductor of the second class, such, for instance, as dilute acid or any electrolyte, then the effect of the feeble potential difference between one pair of copper and zinc disks is added to that of the potential difference between the next pair, and thus by a sufficiently long series of pairs any required difference of potential can be accumulated.

The Voltaic Pile.—This led him about 1799 to devise his famous voltaic pile consisting of disks of copper and zinc or other metals with wet cloth placed between the pairs. Numerous examples of Volta’s original piles at one time existed in Italy, and were collected together for an exhibition held at Como in 1809, but were unfortunately destroyed by a disastrous fire on the 8th of July 1809. Volta’s description of his pile was communicated in a letter to Sir Joseph Banks, president of the Royal Society of London, on the 20th of March 1800, and was printed in the *Phil. Trans.,* vol. 99, pt. 1, p. 405. It was then found that when the end plates of Volta’s pile were connected to an electroscope the leaves diverged either with positive or negative electricity. Volta also gave his pile another form, the couronne des tasses (crown of cups), in which connected strips of copper and zinc were used to bridge between cups of water or dilute acid. Volta then proved that all metals could be arranged in an electromotive series such that each became positive when placed in contact with the one next below it in the series. The origin of the electromotive force has been much discussed, and Volta’s discoveries gave rise to one of the historic controversies of science. Volta maintained that the mere contact of metals was sufficient to produce the electrical difference of the end plates of the pile. The discovery that chemical action was involved in the process led to the advancement of the chemical theory of the pile and this was strengthened by the growing insight into the principle of the conservation of energy. In 1871 Lord Kelvin (Sir W. Thomson), by the use of his then newly-invented electrometer, was able to confirm Volta’s observations on contact electricity by irrefutable evidence, but the contact theory of the voltaic pile was then placed on a basis consistent with the principle of the conservation of energy. A. A. de la Rive and Faraday were ardent supporters of the chemical theory of the pile, and even at the present time opinions of physicists can hardly be said to be in entire accordance as to the source of the electromotive force in a voltaic couple or pile.

Improvements in the form of the voltaic pile were almost immediately made by W. Cruickshank (1745–1800), Dr W. H. Wollaston and Sir H. Davy, and these, together with other eminent continental chemists, such as A. F. de Fourcroy, L. J. Thénard and J. W. Ritter (1776–1810), ardently prosecuted research with the new instrument. One of the first discoveries made with it was its power to electrolyse or chemically decompose certain solutions: Thomas Nicholas (1753–1815) and Sir William Stronge Carlisle (1768–1835) in 1800 demonstrated the passage of silver and zinc plates, and placing the terminal wires in water noticed the evolution from these wires of bubbles of gas, which they proved to be oxygen and hydrogen. These two gases, as Cavendish and James Watt had shown in 1784, were actually the constituents of water. From that date it was clearly recognized that a fresh implement of great power had been given to the chemist. Large voltaic piles were then constructed by Andrew Crosse (1784–1852) and Sir H. Davy, and new experiments initiated by Wollaston and Robert Ware (1781–1858) of Philadelpinia. In 1806 Davy communicated to the Royal Society of London a celebrated paper on some "Chemical Agencies of Electricity," and after providing himself at the Royal Institution of London with a battery of several hundred cells, he announced in 1807 his great discovery of the electrolytic decomposition of the alkalis, potash and soda, obtaining therefrom the metals potassium and sodium and solutions of sodium and potassium, and thus becoming one of the first before the managers of the Royal Institution that they would set on foot a subscription for the purchase of a specially large voltaic battery; as a result he was provided with 20000 pairs of plates, and the first experiment performed with it was the production of the electric arc light between carbon poles. Davy followed up his initial work with a long and brilliant series of electrochemical investigations described for the most part in the *Phil. Trans. of the Royal Society.

Magnetic Action of Electric Current.—Noticing an analogy between the polarity of the voltaic pile and that of the magnet, philosophers had long been anxious to discover a relation between the two, but twenty years elapsed after the invention of the pile before Hans Christian Oersted (1777–1851), professor of natural philosophy in the university of Copenhagen, made in 1819 the discovery which has immortalized his name. In the *Annals of Philosophy* (1820, vol. 2, p. 275) he describes the discovery of Oersted’s original Latin essay (entitled "Experiments on the Effect of a Current of Electricity on the Magnetic Needle"), dated the 21st of July 1820, describing his discovery. In it Oersted describes the action he considers is taking place around

1 Modern researches have shown that the loss of charge is in fact dependent upon the ionization of the air, and that, provided the atmospheric moisture is prevented from condensing on the insulating surface, water vapor in the air does not per se bestow on it conductance for electricity.
the conductor joining the extremities of the pile, he speaks of it as the electric conflict, and says: "It is sufficiently evident that the electric conflict is not confined to the conductor, but is dispersed pretty widely in the circumjacent space. We may likewise conclude that this conflict performs circles round the wire, for without this condition it seems impossible that one part of the wire when placed below the magnetic needle should drive its pole to the east, and when placed above it, to the west."

Oersted's important discovery was the fact that when a wire joining the end plates of a voltaic pile is held near a pivoted magnet or compass needle, the latter is depressed and places itself more or less transversely to the wire. The action depended upon whether the wire is above or below the needle, and on the manner in which the copper or zinc ends of the pile are connected to it. It is clear, moreover, that Oersted clearly recognized the existence of what is now called the magnetic field round the conductor. This discovery of Oersted, like that of Volta, stimulated philosophical investigation in a high degree.

Electricity.—On the 2nd of October 1820, A. M. Ampère presented to the French Academy of Sciences an important memoir, in which he summed up the results of his own and D. F. J. Arago's previous investigations in the new science of electromagnetism, and crowned that labour by the announcement of his great discovery of the dynamical action between conductors conveying the electric currents. Ampère in this paper gave an account of his discovery that conductors conveying electric currents exert a mutual attraction or repulsion on one another, currents of the same direction attracting, and those in opposite directions repelling. Respecting this achievement when developed in its experimental and mathematical completeness, Clerk Maxwell says that it was "perfect in form and unassailable in accuracy." By a series of well-chosen experiments Ampère established the laws of this mutual action, and not only explained observed facts by a brilliant train of mathematical analysis, but predicted others subsequently experimentally realized. These investigations led him to the announcement of the fundamental law of action between elements of current, or currents in infinitely short lengths of linear conductors, upon one another at a distance; summed up in compact expression this law states that the action is proportional to the product of the current strengths of the two elements, and the length of the two elements, and inversely proportional to the square of the distance between the two elements, and this proportionality is independent of the lines of force depending on which the current is exerting on the elements. Nothing is more remarkable in the history of discovery than the manner in which Ampère seized upon the right clue which enabled him to disentangle the complicated phenomena of electromagnetism and to deduce them all as a consequence of one simple fundamental law, which occupies in electro-dynamics the position of the Newtonian law of gravitation in physical astronomy.

In 1821 Michael Faraday (1791–1867), who was destined later on to do so much for the science of electricity, discovered electromagnetic rotation, having succeeded in causing a wire conveying a voltaic current to rotate continuously round the pole of a permanent magnet. This experiment was repeated in a variety of forms by A. A. de la Rive, Peter Barlow (1776–1862), William Ritchie (1790–1837), William Sturgeon (1783–1856), and others; and Davy (Phil. Trans., 1823) showed that when two wires connected with the pole of a battery were dipped into a cup of mercury placed on the pole of a powerful magnet, the fluid rotated in opposite directions about the two electrodynamism.—In 1820 Arago (Ann. Chim. Phys., 1820, 15, p. 94) and Davy (Annals of Philosophy, 1821) discovered independently the power of the electric current to magnetize iron and steel. Félix Savary (1797–1841) made some very curious observations in 1827 on the magnetization of steel needles placed at different distances from a wire conveying the discharge of a Leyden jar (Ann. Chim. Phys., 1827, 14). W. Sturgeon in 1824 wound a copper wire round a bar of iron bent in the shape of a horseshoe, and passing a voltaic current through the wire showed that the iron became powerfully magnetized as long as the connexion with the pile was maintained (Trans. Soc. Arts, 1825). These researches gave us the electromagnet, almost as potent an instrument of research and invention as the pile itself (see ELECTROMAGNETISM).

Ampère had already previously shown that a spiral conductor or solenoid when traversed by an electric current possesses magnetic polarity, and that two such solenoids act upon one another when traversed by electric currents as if they were magnets. Joseph Henry, in the United States, first suggested the construction of what were then called intensity electromagnets, by winding upon a horseshoe-shaped piece of soft iron many superimposed windings of copper wires, insulated by covering it with silk or cotton, and then sending through the coils the current from a voltaic battery. The dependence of the intensity of magnetization on the strength of the current was subsequently investigated (Pogg. Ann. Phys., 1839, 47) by H. F. E. Lens (1804–1865) and M. H. von Jacobi (1801–1874). J. P. Joule found that magnetization did not increase proportionately with the current, but reached a maximum (Sturgeon's Annals of Electricity, 1839, 4). Further investigations on this subject were carried on concurrently by William Sturgeon (1806–1891), J. H. J. Müller (1809–1875), C. J. Duh (1817–1873), G. H. Wiedemann (1826–1890), and others, and in modern times by H. A. Rowland (1848–1901), Shelford Bidwell (b. 1848), John Hopkinson (1849–1868), J. A. Ewing (b. 1855) and many others. Electric magnets of great power were soon constructed in this manner by Sturgeon, Joule, Henry, Faraday and Brewster. Oersted's discovery in 1819 was indeed epoch-making in the degree to which it stimulated other research. It led at once to the construction of the galvanometer as a means of detecting and measuring the electric current in a conductor. In 1820 J. S. C. Schweigger (1779–1857) with his "multiplier" made an advance upon Oersted's discovery, by winding the wire conveying the electric current many times round the pivoted magnetic needle and thus increasing the deflection; and L. Nobili (1784–1833) in 1825 conceived the ingenious idea of neutralizing the directive effect of the earth's magnetism by means of a pair of magnets placed in opposite directions, one on each axis, but with their magnetic poles pointing in opposite directions. Hence followed the astatic multiplying galvanometer.

Electricity.—The study of the relation between the magnet and the circuit conveying an electric current then led Arago to the discovery of the "magnetism of rotation." He found that a vibrating magnetic compass needle came to rest sooner when placed over a plate of copper than otherwise, and also that a plate of copper rotating under a suspended magnet tended to drag the magnet in the same direction.

The matter was investigated by Charles Babbage, Sir J. F. W. Herschel, Peter Barlow and others, but did not receive a final explanation until after the discovery of electromagnetic induction by Faraday in 1831. Ampère's investigations led electricians to see that the force acting upon a magnetic pole due to a current in a neighbouring conductor was such as to tend to cause the pole to travel round the conductor. Much ingenuity had, however, to be expended before a method was found of exhibiting such a rotation. Faraday first succeeded by the simple but ingenious device of using a light magnetic needle tethered flexibly to the bottom of a cup containing mercury so that one pole of the magnet was just above the surface of the mercury. On bringing down on to the mercury surface a wire conveying an electric current, and allowing the current to pass through the mercury and out at the bottom, the magnetic pole at once began to rotate around the wire. Richard, St. John, Audouard, Faraday and others then discovered, as already mentioned, means to make the conductor conveying the current rotate round a
magnetic pole, and Ampère showed that a magnet could be made to rotate on its own axis when a current was passed through it. The difficulty in this case consisted in discovering means by which the current could be passed through one half of the magnet without passing it through the other half. This, however, was overcome by sending the current out at the centre of the magnet by means of a short length of wire dipping into an annular groove containing mercury. Barlow, Sturgeon and others then showed that a copper disk could be made to rotate between the poles of a horseshoe magnet when a current was passed through the disk. In order to secure to the circumference, the disk being kept at the same time freely movable by making a contact with the circumference by means of a mercury trough. These experiments furnished the first elementary forms of electric motor, since it was then seen that rotary motion could be produced in masses of metal by the mutual action of conductors conveying electric current and magnetic fields. By his discovery of thermo-electricity in 1821 (Fogg. Ann. Phys., 6), T. J. Seebeck (1770-1831) opened up a new region of research (see THERMO-ELECTRICITY). James Cuming (1777-1861) in 1823 (Annals of Philosophy, 1823) found that the thermo-electric series varied with the temperature, and J. C. A. Peltier (1785-1845) in 1834 discovered that a current passed across the junction of two metals either generated or absorbed heat.

Ohm's Law.—In 1827 Dr G. S. Ohm (1787-1854) rendered a great service to electrical science by his mathematical investigation of the electric circuit, and in the publication of his paper, "Ueber die Beziehung zwischen den Eigenschaften der Leiter und der Stromstärke derselben," in 1827. Before his time, ideas on the measurable quantities with which we are concerned in an electric circuit were extremely vague. Ohm introduced the clear idea of current strength as an effect produced by electromotive force acting as a cause in a circuit having resistance as its quality, and showed that the current was directly proportional to the electromotive force and inversely as the resistance. Ohm's law, as it is called, was based upon an analogy with the flow of heat in a circuit, discussed by Fourier. Ohm introduced the definite conception of the distribution along the circuit of "electroscopic force" or tension (Spannung), corresponding to the modern term potential. Ohm verified his law by the aid of thermo-electric piles as sources of electromotive force, and Davy, C. S. M. Pouillet (1791-1866), A. C. Becquerel (1788-1878), G. T. Fechner (1800-1887), R. H. A. Kohlrausch (1800-1858) and others laboured at its confirmation. In more recent times, 1876, it was rigorously tested by Maxwell (1831-1879), and although at its original enunciation its meaning was not at first fully apprehended, it soon took its place as the expression of the fundamental law of electrokinetics.

Induction of Electric Currents.—In 1831 Faraday began the investigations on electromagnetic induction which proved more fertile in far-reaching practical consequences than any of those which even his genius gave to which the world. These advances all centre round his supreme discovery of the induction of electric currents. Fully familiar with the fact that an electric charge upon one conductor could produce a charge of opposite sign upon a neighbouring conductor, Faraday asked himself whether an electric current passing through a conductor could not in any like manner induce an electric current in some neighbouring conductor. His first experiments on this subject were made in the month of November 1825, but it was not until the 9th of August 1831 that he attained success. On that date he had provided himself with an iron ring, over which he had wound two coils of insulated copper wire. One of these coils was connected with the voltaic battery and the other with the galvanometer. He found that at the moment the current in the battery circuit was started or stopped, transitory currents appeared in the galvanometer circuit in opposite directions. In ten days of brilliant investigation, guided by clear insight from the very first into the meaning of the phenomena concerned, he established experimentally the fact that a current may be induced in a conducting circuit simply by the variation in a magnetic field, the lines of force of which are linked with that circuit. The whole of Faraday's investigations on this subject can be summed up in the simple statement that if a conducting circuit is placed in a magnetic field, and if either by variation of the field or by movement or variation of the form of the circuit the total magnetic flux linked with the circuit is varied, an electromotive force is set up in that circuit which at any instant is measured by the rate at which the total flux linked with the circuit is changing.

Amongst the memorable achievements of the ten days which Faraday devoted to this investigation was the discovery that a current could be induced in a conducting wire simply by moving it in the neighbourhood of a magnet. One form which this experiment took was that of rotating a copper disk between the poles of a powerful electric magnet. He then found that a conductor, the ends of which were connected respectively with the centre and edge of the disk, was traversed by an electric current. This important fact laid the foundation for all subsequent inventions which finally led to the production of electromagnetic or dynamo-electric machines.

Third Period.—With this supremely important discovery of Faraday's we enter upon the third period of electrical research. In which that philosopher himself was the leading figure. He not only collected the facts concerning electromagnetic induction so industriously that nothing of importance remained for future discovery, and embraced them all in one law of exquisite simplicity, but he introduced his famous conception of lines of force which changed entirely the mode of regarding electrical phenomena. The French mathematicians, Coulomb, Bina, Poisson and Ampère, had been content to accept the fact that electric charges or currents in conductors could exert forces on other charges or conductors at a distance without inquiring into the means by which this action at a distance was produced. Faraday's mind, however, revolted against this notion; he felt intuitively that these distance actions must be the result of unseen operations in the interposed medium. Accordingly when he sprinkled iron filings on a card held over a magnet and revealed the curvilinear system of lines of force (see MAGNETISM), he regarded these fragments of iron as simple indicators of a physical state in the space already in existence round the magnet. To him a magnet was not simply a bar of steel; it was the core and origin of a system of lines of magnetic force attached to it and moving with it. Similarly he came to see an electrified body as a centre of a system of lines of electrostatic force. All this is laid down in his "Lectures to Students" (1854). Therefore to Faraday the seat of corresponding lines of magnetic or electric force. He proved by systematic experiments that the electromotive forces set up in conductors by their motions in magnetic fields or by the induction of other currents in the field were due to the secondary conductor cutting lines of magnetic force. He invented the term "electrotonic state" to signify the total magnetic flux due to a conductor conveying a current, which was linked with any secondary circuit in the field or even with itself.

Faraday's Researches.—Space compels us to limit our account of the scientific work done by Faraday in the succeeding twenty years, in elucidating electrical phenomena and adding to the knowledge thereon, to the very briefest mention. We must refer the reader for further information to his monumental work entitled Experimental Researches on Electricity, in three volumes, reprinted from the Phil. Trans. between 1831 and 1851. Faraday divided these researches into various series. The 1st and concern the discovery of magneto-electric induction already mentioned. The 3rd series (1833) he devoted to discussion of the identity of electricity derived from various sources, frictional, voltaic, animal and thermal, and he proved by rigorous experiments the identity and similarity in properties of the electricity generated by these various methods. The 5th series (1835) is occupied with his electrochemical researches. In the 7th series (1839) he defines a number of new terms, such as electrolyte, electrolysis, anode and cathode, &c., in connexion with electrolytic phenomena, which were immediately adopted into the vocabulary of science. His most important contribution at
ELECTRICITY

this date was the invention of the voltmeter and his enunciation of the law of electrostatics. The voltmeter provided a means of ascertaining quantity of electricity, and in the hands of Faraday and his successors became an appliance of fundamental importance. The 8th series (1834) he announced the discovery of the important property of electric conductors, since called their self-induction or reactance, a discovery in which, however, he was anticipated by Joseph Henry in the United States. The 11th series (1837) deals with electrostatic induction and the statement of the important fact of the specific inductive capacity of insulators or dielectrics. This discovery was made in November 1837 when Faraday had no knowledge of Cavendish’s previous researches into this matter. The 10th series (1843) contains an account of his brilliant discovery of the rotation of the plane of polarized light by transparent dielectrics placed in a magnetic field, a relation which established for the first time a practical connexion between the phenomena of electricity and light. The 20th series (1845) contains an account of his researches on the universal action of magnetism and diamagnetic bodies. The 22nd series (1848) is occupied with the discussion of magneto-crystalline force and the abnormal behaviour of various crystals in a magnetic field. In the 25th series (1850) he made known his conclusion that the magnetic characteristics of oxygen and hydrogen are important principle that the terms paramagnetic and diamagnetic are relative. In the 26th series (1850) he returned to a discussion of magnetic lines of force, and illuminated the whole subject of the magnetic circuit by his transcendent insight into the intricate phenomena concerned. In 1855 he brought these researches to a conclusion by a general article on magnetic philosophy, having placed the whole subject of magnetism and electromagnetism on an entirely novel and solid basis, and added to this he provided the means for studying the phenomena, not only qualitatively, but also quantitatively, by the profoundly ingenious instruments he invented for that purpose.

Electrical Measurement.—Faraday’s ideas thus pressed upon electricians the necessity for the quantitative measurement of electrical phenomena.\(^1\) It has been already mentioned that Schweigger invented in 1820 the “multipiler,” and Nobili in 1825 the astatic galvanometer. C. M. Poullet in 1831 contributed to the design of a great improvement in one of the best known instruments, and W. E. Weber, George Thompson's portrait, 1853. The American inventor, was an active worker in the art of measurement. In 1849 H. von Helmholtz devised a tangent galvanometer with two coils. The measurement of electric resistance then engaged the attention of electricians. By his Memoirs in the Phil. Trans. in 1843, Sir Charles Wheatstone gave a great impulse to this study. He invented the rheostat and improved the resistance balance, invented by S. H. Christie (1784–1865) in 1833, and subsequently called the Wheatstone Bridge. (See his Scientific Papers, published by the Physical Society of London, p. 120.) Weber about this date invented the electrodynamometer, and applied the mirror and scale method of reading deflections, and in co-operation with C. F. Gauss introduced a system of absolute measurement of electric and magnetic phenomena. In 1846 Weber proceeded with improved apparatus to test Ampère’s laws of electromagnetism. In 1845 H. G. Graaffman (1809–1897) published (Phil. Trans. vol. 64) his “Neue Theorie der Electrodynamik,” in which he gave an elementary law differing from that of Ampère but leading to the same results for closed circuits. In the same year F. E. Neumann published another law. In 1846 Weber announced his famous hypothesis concerning the connexion of electrostatic and electromagnetic phenomena. The work of Neumann and Weber has been stimulated by that of H. F. E. Leitz (1804–1865), whose researches (Pogg. Ann., 1834, 31; 1835, 34) among other results led him to the conclusion that by means of which the direction of the induced current can be predicted from the theory of Ampère, the rule being that the direction of the induced current is always such that its electrodynamic action tends to oppose the motion which produces it.

Neumann in 1845 did for electromagnetic induction what Ampère did for electrodynamics, basing his researches upon the experimental laws of Lenz. He discovered a function, which has been called the potential of one circuit on another, from which he deduced a theory of induction, completely in accordance with experiment. Weber at the same time deduced the mathematical laws of induction from his elementary law of electrical action, and with his improved instruments arrived at accurate verifications of the law of induction which by this time had been developed mathematically by Neumann and himself. In 1849 G. R. Kirchhoff determined experimentally in a certain case the absolute value of the current induced by one circuit in another, and in the same year Erik Edland (1819–1888) made a series of careful experiments on the induction of electric currents which further established received theories. These labours laid the foundation on which was subsequently erected a complete system for the absolute measurement of electric and magnetic quantities, referring them all to the fundamental units of mass, length and time. Helmholtz gave at the same time a mathematical theory of induced currents and a valuable application of the experiments on them (Pogg. Ann., 1851). This great investigator and luminous expositor of physical facts, before the time had published his celebrated essay, Die Erhaltung der Kraft ("The Conservation of Energy"), which brought to a focus ideas which had been accumulating in consequence of the work of J. P. Joule, J. R. von Mayer and others, on the transformation of various forms of physical energy, and in particular the mechanical equivalent of heat. Helmholtz brought to bear upon the subject not only the most profound mathematical attainments, but immense experimental skill, and his work in connexion with this subject is classical.

Lord Kelvin's Work.—About 1842 Lord Kelvin (then William Thomson) began that long career of theoretical and practical discovery and invention in electrical science which revolutionized every department of pure and applied electricity. His early contributions to electrosstatics and electrometry are to be found described in his Reprint of Papers on Electrodynamics and Magnetism (1872), and his later views in his collected papers on Electrical and Physical Papers. By his studies in electrosstatics, his elegant method of electrical images, his development of the theory of potential and application of the principle of conservation of energy, as well as by his inventions in connexion with electrometry, he laid the foundations of our modern knowledge of electrosstatics. His work on the electrodynamic qualities of metals, thermo-electricity, and his contributions to galvanometry, were not less massive and profound. From 1842 onwards to the end of the 19th century, he was one of the great master workers in the field of electrical discovery and research.\(^2\) In 1853 he published a paper "On Transient Electric Currents" (Phil. Mag., 1853 [4], 5, p. 393), in which he applied the principle of the conservation of energy to the discharge of a Leyden jar. He added definiteness to the idea of the self-induction or inductance of an electric circuit, and gave a mathematical expression for the current flowing out of a Leyden jar during its discharge. He confirmed an opinion already previously expressed by Helmholtz and by Henry, that in some circumstances this discharge is oscillatory in nature, consisting of an alternating electric current of high frequency. These theoretical predictions were confirmed and others, subsequently, by the work of B. W. Feddersen (b. 1832), C. A. Paalzow (b. 1823), and it was then seen that the familiar phenomena of the discharge of a Leyden jar, and the concomitant oscillations, are a natural consequence of the theory of electricity. In this connexion the work of George Green (1793–1841) must not be forgotten. Green's Essay on the Application of Mathematical Analysis to the Theory of Electricity and Magnetism, published in 1828, contains the first exposition of the theory of potential. An important theorem contained in it is known as Green's theorem, and is of great value.
ELECTRICITY

The means of generating electric oscillations of very high frequency.

Telegraphy.—Turning to practical applications of electricity, we may note that electric telegraphy took its rise in 1820, beginning with a suggestion of Ampère immediately after Oersted's discovery. It was established by the work of Weber and E. G. Grosch in 1832, by C. A. Steinheil (1801-1870) of Munich, Sir W. F. Cooke (1806-1879) and Sir C. Wheatstone in England, Joseph Henry and S. F. B. Morse (1791-1872) in the United States in 1837. In 1845 submarine telegraphy was inaugurated by the laying of an insulated conductor across the English Channel by the brothers Brett, and their temporary success was followed by the laying in 1851 of a permanent Dover-Calais cable by T. E. Crompton. In 1856 the project for an Atlantic submarine cable took shape, and the Atlantic Telegraph Company was formed with a capital of £350,000, with Sir Charles Bright as engineer-in-chief and E. O. W. Whitehouse as electrician. The phenomena connected with the propagation of electric signals by underground insulated wires had already engaged the attention of Faraday in 1854, who pointed out the Leyden-jar-like action of an insulated subterranean wire. Scientific and practical questions connected with the position of laying an Atlantic submarine cable then began to be discussed, and Lord Kelvin was foremost in developing true scientific knowledge on this subject, and in the invention of appliances for utilizing it. One of his earliest and most useful contributions (in 1858) was the invention of the mirror galvanometer. Abandoning the long and somewhat heavy magnetic needles that had been used up to that date in galvanometers, he attached to the back of a very small mirror made of microscopic glass a fragment of magnetized watch-spring, and suspended the mirror and needle by means of a cocon fibre in the centre of a coil of insulated wire. By this simple device he provided a means of measuring small electric currents far in advance of anything yet accomplished, and this instrument proved not only most useful in pure scientific researches, but at the same time was of the utmost value in connexion with submarine telegraphy. The history of the initial failures and final success in laying the Atlantic cable has been well told by Mr. Charles Bright (see The Story of the Atlantic Cable, London, 1903). The first cable laid in 1857 broke on the 11th of August during laying. The second attempt in 1858 was successful, but the cable completed on the 5th of August 1858 broke down on the 20th of October 1858, after 732 messages had passed through it. The third cable laid in 1865 was lost on the 2nd of August 1865, but in 1866 a final success was attained and the 1865 cable also recovered and completed. Lord Kelvin's mirror galvanometer was used for receiving signals through the short-lived 1858 cable. In 1867 he invented his beautiful siphon-recorder for receiving and recording the signals through long cables. Later, in conjunction with Prof. Fleeming Jenkin, he devised his automatic curb sender, an appliance for sending signals by means of punched telegraphic paper tape. Lord Kelvin's contributions to the science of exact electric measurement were enormous. His amperes-balances, voltmeters and electrometers, and double bridge, are elsewhere described in detail (see AMPÈRE-METER; ELECTROMETER, and WHEATSTONE'S BRIDGE).

Dynamo.—The work of Faraday from 1831 to 1837 stimulated and originated an immense mass of scientific research, but at the same time practical inventors had not been slow to perceive that it was capable of purely technical application. Faraday's copper disk rotated between the poles of a magnet, and producing thereby an electric current, became the parent of innumerable machines in which mechanical energy was directly converted into the energy of electric currents. Of these machines, originally called magneto-electric machines, one of the first was devised in 1834, by H. Pixii. It consisted of a fixed horse-shoe armature wound over with insulated copper wire in front of which revolved a vertical axis a horse-shoe magnet. Pixii invented the contrivance of condensing the alternating current so produced into a continuous current in the external circuit, which was followed by J. Saxton, E. M. Clarke, and many others in the development of the above-described magneto-electric machine. In 1857 E. W. Siemens effected a great improvement by inventing a shuttle armature and improving the shape of the field magnet. Subsequently similar machines with electromagnets were introduced by Henry Wilde (b. 1855), Siemens, Wheatstone, W. Ladd and others, and the principle of self-excitation was suggested by Wilde, C. F. Varley (1828-1883), Siemens and Wheatstone (see DYNAMO). These machines about 1866 and 1867 began to be constructed on a commercial scale and were employed in the production of the electric light. The discovery of electric-current induction also led to the production of the induction coil (q.v.), improved and brought to its present perfection by W. Sturgeon, E. R. Ritchie, N. J. Callan, H. Cephas, A. H. L. Fiske, and S. P. Mallory, and further improved by A. Apps and modern inventors. About the same time Fizeau and J. B. L. Foucault devoted attention to the invention of automatic apparatus for the production of Davy's electric arc (see LIGHTING; ELECTRIC), and these appliances in conjunction with magneto-electric machines were soon employed in lighthouse work. With the advent of large magneto-electric machines the era of electrotechnics was fairly entered, and this period, which may be said to terminate about 1887 to 1889, was consummated by the theoretical work of Clerk Maxwell.

Maxwell's Researches.—James Clerk Maxwell (1831-1879) entered on his electrical studies with a desire to ascertain if the ideas of Faraday, so different from those of Poisson and the French mathematicians, could be made the foundation of a mathematical method and brought under the power of analysis. Maxwell started with the conception that all electric and magnetic phenomena are due to effects taking place in the dielectric or in the ether if the space be vacuous. The phenomena of light had compelled physicists to postulate a space-filling medium, to which the name ether had been given, and Henry and Faraday had long previously suggested the idea of an electromagnetic medium. The vibrations of this medium constitute the agency called light. Maxwell saw that it was unphilosophical to assume a multiplicity of ethers or media until it had been proved that one would not suffice for all requirements. He formulated the conception, therefore, of electric charge as oscillating in the environment taking place in the dielectric or electromagnetic medium (see ELECTROSTATICS). Maxwell never committed himself to a precise definition of the physical nature of electric displacement, but considered it as defining that which Faraday had called the polarization in the insulator, or, what is equivalent, the number of lines of electrostatic force passing normally through a unit of area in the dielectric. A second fundamental conception of Maxwell was that the electric displacement whilst it is changing is in effect an electric current, and creates, therefore, magnetic force. The total current at any point in a dielectric must be considered as made up of two parts: first, the true conduction current, if it exists; and second, the rate of change of dielectric displacement. The fundamental fact connecting electric currents and magnetic fields is that the line integral of magnetic force taken once round a conductor conveying an electric current is equal to 4 n-times the surface integral of the current in a closed line round which the integral is taken (see ELECTROKINETICS). A second relation connecting magnetic and electric force is

1 See also his Submarine Telegraphs (London, 1898).
2 The quantitative study of electrical phenomena has been enormously extended by the establishment of the absolute system of electrical measurement due originally to Gauss and Weber. The British Association for the advancement of science appointed in 1861 a committee on electrical units, which made its first report in 1862 and has existed ever since. In this work Lord Kelvin took a leading part. The popularization of the system was greatly assisted by the publication by Prof. J. D. Everett of The C.G.S. System of Units (London, 1891).
based upon Faraday's fundamental law of induction, that the rate of change of the total magnetic flux linked with a conductor is a measure of the electromotive force created in it (see ELECTROKINETICS). Maxwell also introduced in this connexion the notion of the vector potential. Coupling together these ideas he was finally enabled to prove that the propagation of electric and magnetic waves takes place with a velocity determined by the dielectric constant and the magnetic permeability of the medium. To take a simple instance, if we consider an electric current as flowing in a conductor it is, as Oersted discovered, surrounded by closed lines of magnetic force. If we imagine the current in the conductor to be instantaneously reversed in direction, the magnetic force surrounding it would not be instantly reversed everywhere in direction, but the reversal would be propagated outwards through space with a certain velocity which Maxwell showed was inversely as the square root of the product of the magnetic permeability and the dielectric constant or specific inductive capacity of the medium.

These great results were announced by him for the first time in a paper presented in 1864 to the Royal Society of London and printed in the Phil. Trans. for 1865, entitled "A Dynamical Theory of Magnetic and Electric Forces." In this paper that the velocity of propagation of an electromagnetic impulse through space could also be determined by certain experimental methods which consisted in measuring the same electric quantity, capacity, resistance or potential in two ways. W. E. Weber had already laid the foundations of the absolute system of electric and magnetic measurement, and proved that a quantity of electricity could be measured either by the force it exercises upon another static or stationary quantity of electricity, or magnetically by the force this quantity of electricity exercises upon a magnetic pole when flowing through a neighbouring conductor. The two systems of measurement were called respectively the electrostatic and the electromagnetic systems (see UNITS, PHYSICAL). Maxwell suggested new methods for the determination of this ratio of the electrostatic to the electromagnetic units, and by experiments of great ingenuity was able to show that this ratio, which is also that of the velocity of the propagation of an electromagnetic impulse through space, is identical with that of light. This great fact once ascertained, it became clear that the notion that electric phenomena are affections of the luminiferous ether was no longer a mere speculation but a scientific theory capable of verification. An immediate deduction from Maxwell's theory was that in transparent dielectrics, the dielectric constant or specific inductive capacity should be numerically equal to the square of the refractive index for very long electric waves. At the time when Maxwell developed his theory the dielectric constants of only a few transparent insulators were known and these were for the most part measured with steady or unidirectional electromotive force. The only refractive indices which had been measured were the optical refractive indices of a number of transparent substances. Maxwell made a comparison between the optical refractive index and the dielectric constant of paraffin wax, and the approximation between the numerical values of the square of the first and that of the last was sufficient to show that there was a basis for further work. Maxwell's electric and magnetic ideas were gathered together in a great mathematical treatise on electricity and magnetism which was published in 1873. This book stimulated in a most remarkable degree theoretical and practical research into the phenomena of electricity and magnetism. Experimental methods were devised for the further exact measurements of the electromagnetic velocity and numerous determinations of the magneto-metric units were made. The results were put in general comparison with the corresponding magneto-optical results and the correspondence between the empirical results was found to be very close. Thus the optical refractive index for long waves and the dielectric constant of the same substance were sufficiently close to afford an apparent confirmation of Maxwell's theory, yet in other cases there were considerable divergencies. L. Boltzmann (1844-1906) made a number of determinations for solids and for gases, and the dielectric constants of many solid and liquid substances were determined. A small space will be devoted to a discussion of some of these results by P. A. Silow (b. 1850), J. Hopkinson and others. The accumulating determinations of the numerical value of the electromagnetic velocity (c) from the earliest made by Lord Kelvin (Sir W. Thomson) with the aid of King and Michie, or those of Clerk Maxwell, W. E. Ayrton and J. Perry, to more recent ones by J. J. Thomson, F. Himstedt, H. A. Rowland, E. B. Rosa, J. S. H. Pellat and H. A. Abraham, showed it to be very close to the best determinations of the velocity of light (see UNITS, PHYSICAL). On the other hand, the divergence in some cases between the square of the optical refractive index and the dielectric constant was very marked. Hence although Maxwell's theory of electrical action when first propounded found many adherents in Great Britain, it did not so much dominate opinion on the continent of Europe.

Fourm Parzen.—With the publication of Clerk Maxwell's "Electricity and Magnetism" in 1873, we enter upon the fourth and last period of electrical research. On the technical side the invention of a new form of armature for dynamo electric machines by Z. T. Gramme (1826-1901) inaugurated a departure from which we may date modern electrical engineering. It will be convenient to deal with technical development first.

Technical Development.—As far back as 1841 large magnetoelectric machines driven by steam power had been constructed, and in 1856 F. H. Holmes had made a magneto machine with multiple permanent magnets which was installed in 1862 in Dungeness lighthouse. Further progress was made in 1867 when H. Wilde introduced the use of electromagnets for the field magnets. In 1860 Dr Antonio Pacinotti invented what is now called the toothed ring winding for armatures and described it in an Italian journal, but it attracted little notice until reinvented in 1870 by Gramme. In this new form of bobbin, the armature consisted of a ring of iron wire wound over with an endless coil of wire and connected to a commutator consisting of copper bars insulated from one another. Gramme dynamos were then soon made on the self-exciting principle. In 1873 at Vienna the fact was discovered that a dynamo machine of the Gramme type could also act as an electric motor and was set in rotation when a current was passed into it from another similar machine. Henceforth the electric transmission of power came within the possibilities of engineering.

Electric Lighting.—In 1876, Paul Jablonski (1847-1894), a Russian officer, passing through Paris, invented his famous electric candle, consisting of two rods of carbon placed side by side and separated from one another by an insulating material. This invention in conjunction with an alternating current dynamo provided a new and simple form of electric arc lighting. Two years afterwards C. F. Brush, in the United States, produced another efficient form of dynamo and electric arc lamp suitable for working in series (see LIQUINOX: ELECTRIC), and these inventions of Brush and Jablonski inaugurated commercial arc lighting. The so-called subdivision of electric light by incandescent lighting lamps then engaged attention. E. A. King in 1845 and W. E. Staitte in 1848 had made incandescent electric lamps of an elementary form, and T. A. Edison in 1878 again attacked the problem of producing light by the incandescence of platinum. It had by that time become clear that the most suitable material for an incandescent lamp was carbon containing under certain conditions of vacuum, of various carbon, like the carbon in England, and T. A. Edison in the United States, were engaged in struggling with the difficulties of producing a suitable carbon incandescent electric lamp. Edison constructed in 1879 a successful lamp of this type consisting of a vessel wholly of glass containing a carbon filament made by carbonizing paper or some other carbonizable material, the vessel being exhausted and the current led into the filament through platinum wires.
In 1879 and 1880, Edison in the United States, and Swan in conjunction with C. H. Stearn in England, succeeded in completely solving the practical problems. From and after that date incandescent electric lighting began to be commercially feasible and was brought to public notice chiefly by an electrical exhibition held at the Crystal Palace, near London, in 1882. Edison, moreover, as well as Lane-Fox, had realized the idea of a public electric supply station, and the former proceeded to establish in Pearl Street, New York, in 1881, the first public electric supply station. A similar station in England was opened in the basement of a house in Holborn Viaduct, London, in March 1882. Edison, with copious ingenuity, devised electric meters, electric mains, lamp fittings and generators complete for the purpose. In 1882 C. A. Faure made an important improvement in the lead secondary battery which G. Planté (1834-1888) had invented in 1859, and storage batteries then began to be developed as commercial appliances by Faure, Swan, J. S. Sellon and many others (see Accumulator). In 1883, numerous electric lighting companies were formed for the conduct of public and private lighting, but an electric lighting act passed in that year greatly hindered commercial progress in Great Britain. Nevertheless the delay was utilized in the completion of inventions necessary for the safe and economical distribution of electric current for the purpose of electric lighting.

Telephone.—Going back a few years we find the technical applications of electrical invention had developed themselves in other directions. Alexander Graham Bell in 1876 invented the speaking telephone (q.v.), and Edison and Elisha Gray in the following year followed and developed dynamos with other telephonic inventions for electrically transmitting speech. About the same time D. E. Hughes in England invented the microphone. In 1879 telephone exchanges began to be developed in the United States, Great Britain and other countries. Electric Power.—Following on the discovery in 1873 of the reversible action of the dynamo and its use as a motor, efforts began to be made to apply this knowledge to transmission of power, and S. D. Field, T. A. Edison, Leo Daft, E. M. Bentley and W. H. Knight, F. J. Sprague, C. J. Van Depoele and others between 1880 and 1884 were the pioneers of electric traction. One of the earliest electric trams cars was exhibited by E. W. and W. Siemens in Paris in 1881. In 1883 Lucien Gaulard, following a line of thought opened by Jablonski, proposed to employ high pressure alternating currents for electric distributions over wide areas by means of transformers. His ideas were improved by Carl and O. T. Bldhy in Hungary and by S. Z. de Ferranti in England, and the alternating current transformer (see Transformers) came into existence. Polyphase alternators were first exhibited at the Frankfurt electrical exhibition in 1891, developed as a consequence of scientific researches by Galileo Ferraris (1847-1897), Nikola Tesla, M. O. von Dolivo-Dobrovolsky and C. E. L. Brown, and long distance transmission of electric power by polyphase electrical currents (see Power Transmission: Electric) was exhibited in operation at Frankfurt in 1891. Meanwhile the early continuous current dynamos devised by Gramme, Siemens and others had been vastly improved in scientific principle and practical construction by the labours of Siemens, J. Hopkinson, R. E. B. Crompton, Elihu Thomson, Rudolf Eickemeyer, Thomas Parker and others, and the theory of the action of the dynamo had been closely studied by J. and E. Hopkinson, G. Kapp, S. P. Thompson, C. P. Steinmetz and J. Swinburne, and great improvements made in the alternating current dynamo by W. M. Morley, S. Z. de Ferranti and Messrs. Ganz of Budapest. Thus in twenty years from the invention of the Gramme dynamo, electrical engineering had developed from small beginnings into a vast industry. The amendment, in 1888, of the Electric Lighting Act of 1882, before long caused a huge development of public electric lighting in Great Britain. By the end of the 19th century every large city in Europe and in North and South America was provided with a public electric supply for the purpose of electric illumination. The improve-ments in electric illuminants, such as the Nernst oxide lamp, the tantalum and osmium incandescent lamps, and improved forms of arc lamp, enclosed, inverted and flame arcs, are described under Lighting: Electric.

Between 1890 and 1900, electric traction advanced rapidly in the United States of America but more slowly in England. In 1902 the success of deep tube electric railways in Great Britain was assured, and in 1904 main line railways began to abandon, at least experimentally, the steam locomotive and substitute for it the electric transmission of power. Long distance electrical transmission had been before that time exemplified in the great scheme of utilizing the falls of Niagara. The first projects were discussed in 1891 and 1892 and completed practically some ten years later. In this scheme large turbines were placed at the bottom of hydraulic fall tubes 150 ft. deep, the turbines being coupled by long shafts with 2000 H.P. alternating current dynamos on the surface. By these electric current was generated and transmitted to towns and factories around, being sent overhead as far as Buffalo, a distance of 18 m. At the end of the 19th century electrochemical industries began to be developed which depended on the possession of cheap electric energy. The production of aluminium in Switzerland and Scotland, carbonium and calcium carbide in the United States, and soda by the Castner-Kellner process, began to be conducted on an immense scale. The early work of Sir W. Siemens on the electric furnace was continued and greatly extended by Henri Moissan and others on its scientific side, and electro-chemistry took its place as one of the most promising departments of technical research and invention. It was stimulated and assisted by improvements in the construction and performance of dynamos, and by increased knowledge concerning the control of powerful electric currents.

In the early part of the 20th century the distribution in bulk of electric energy for power purposes in Great Britain began to assume important proportions. It was seen to be uneconomical for each city and town to manufacture its own supply since, owing to the intermittent nature of the demand for current for lighting, the price had to be kept up to 4d. and 6d. per unit. It was found that by the manufacture in bulk, even by steam engines, at primary centres the cost could be considerably reduced, and in numerous districts in England large power stations began to be erected between 1903 and 1905 for the supply of current for power purposes. This involved almost a revolution in the nature of the tools used, and in the methods of working; and may ultimately even greatly affect the factory system and the concentration of population in large towns which was brought about in the early part of the 19th century by the invention of the steam engine.

Development of Electric Theory.

Turning now to the theory of electricity, we may note the equally remarkable progress made in 300 years in scientific insight into the nature of the agency which has so recast the face of human society. There is no need to dwell upon the early crude theories of the action of amber and lodestone. In a true scientific sense no hypothesis was possible, because few facts had been accumulated. The discoveries of Stephen Gray and C. F. de C. du Fay on the conductivity of some bodies for the electric agency and the dual character of electrification gave rise to the first notions of electricity as an imponderable fluid, or non-gravitative subtle matter, of a more refined and penetrating kind than ordinary liquids and gases. Its duplex character, and the fact that the electricity produced by rubbing glass and vitreous substances was different from that produced by rubbing sealing-wax and resinous substances, seemed to necessitate the assumption of two kinds of electric fluid; hence there arose the conception of positive and negative electricity, and the two-fluid theory came into existence.

Single-fluid Theory.—The study of the phenomena of the Leyden jar and of the fact that the inside and outside coatings possessed opposite electricity, so that in charging the jar the charge was transferred from one to the other, led Franklin about 1750 to suggest a modification called the single fluid theory, in which the two states of electrification
were regarded as not the results of two entirely different fluids but of the addition or subtraction of one electric fluid from matter, so that positive electrification was to be looked upon as the result of increase or addition of something to ordinary matter and negative as a subtraction. The positive and negative electrifications of the two coatings of the Leyden jar were therefore regarded as the result of a transformation of something called electricity from one coating to the other, by which process a certain measurable quantity became so much less on one side by the same amount by which it became more on the other. A modification of this single fluid theory was put forward by F. U. T. Aepinus which was explained and illustrated in his *Tentamen theoriae electricitiatis et magnetismi*, published in St Petersburg in 1759. This theory was founded on the following principles:—(1) the particles of the electric fluid repel each other with a force decreasing as the distance increases; (2) the particles of the electric fluid attract the atoms of all bodies and are attracted by them with a force obeying the same law; (3) the electric fluid exists in the pores of all bodies, and while it moves without any obstruction in conductors such as metals, water, &c., it moves with extreme difficulty in so-called non-conductors such as glass, resin, &c.; (4) electrical phenomena are produced either by the transference of the electric fluid from one body containing more to one containing less, or from its attraction and repulsion when no transference takes place. Electric attractions and repulsions were, however, regarded as differential actions in which the mutual repulsion of the particles of electricity operated, so to speak, in antagonism to the mutual attraction of particles of matter for one another and of particles of electricity for matter. Independently of Aepinus, Henry Cavendish put forward a single-fluid theory of electricity (Phil. Trans., 1771, 61, p. 584), in which he considered it in more precise detail.

Two-fluid Theory.—In the elucidation of electrical phenomena, however, towards the end of the 18th century, a modification of the two-fluid theory seems to have been generally preferred. The notion then formed of the nature of electrification was something as follows:—All bodies were assumed to contain a certain quantity of a so-called neutral fluid made up of equal quantities of positive and negative electricity, which when in this state of combination neutralized one another’s properties. The neutral fluid could, however, be divided up or separated into its two constituents, and these could be accumulated on separate conductors or non-conductors. This view followed from the discovery of the facts of electric induction of J. Canton (1753, 1754). When, for instance, a positively electrified body was found to induce upon another insulated conductor a charge of negative electricity on the side nearest to it, and a charge of positive electricity on the side farthest from it, this was explained by saying that the particles of each of the two electric fluids repelled one another but attracted those of the positive fluid. Hence the operation of the positive charge upon the neutral fluid was to draw towards the positive the negative constituent of the neutral charge and repel to the distant parts of the conductor the positive constituent.

C. A. Coulomb experimentally proved that the law of attraction and repulsion of simple electrified bodies was that the force between them varied inversely as the square of the distance and thus gave mathematical definiteness to the two-fluid hypothesis. It was then assumed that each of the two constituents of the neutral fluid had an atomic structure and that the so-called particles of one of the electric fluids, say positive, repelled similar particles with a force varying inversely as a square of the distance and attracted those of the opposite fluid according to the same law. The fact that a transformation of the phenomena with the domain of mathematical analysis and, as already mentioned, Laplace, Biot, Poisson, G. A. A. Plana (1781–1846), and later Robert Murphy (1806–1843), made them the subject of their investigations on the mode in which electricity distributes itself on conductors when in equilibrium.

Faraday’s Views.—The two-fluid theory may be said to have held the field until the time when Faraday began his researches on electricity. After he had educated himself by the study of the phenomena of lines of magnetic force in his discoveries on electromagnetic induction, he applied the same conception to electrostatic phenomena, and thus created the notion of lines of electrostatic force and of the important function of the dielectric or non-conductor in sustaining them. Faraday’s notion as to the nature of electrification, therefore, about the middle of the 19th century came to be something as follows:—He considered that the so-called charge of electricity on a conductor was in reality nothing on the conductor or in the conductor itself, but consisted in a state of strain or polarization, or a physical change of some kind in the particles of the dielectric surrounding the conductor, and that it was this physical state in the dielectric which constituted electrification. Since Faraday was well aware that even a good vacuum can act as a dielectric, he recognized that the state he called dielectric polarization could not be wholly dependent upon the presence of gravitative matter, but that there must be an electromagnetic medium of a supermaterial nature. In the 13th series of his *Experimental Researches on Electricity* he discussed the relation of a vacuum to electricity. Furthermore his electrochemical investigations, and particularly his discovery of the important law of electrolysis, that the movement of a certain quantity of electricity through an electrolyte is always accompanied by the transfer of a definite quantity of matter from one electrode to another and the liberation at these electrodes of an equivalent weight of the ions, gave foundation for the idea of a definite atomic charge of electricity. In fact, long previously to Faraday’s electrochemical researches, Sir H. Davy and J. J. Berzelius early in the 19th century had advanced the hypothesis that chemical combination was due to electric attractions between the electric charges carried by chemical atoms. The notion, however, that electricity is atomic in structure was definitely put forward by Hermann von Helmholtz in a well-known Faraday lecture. Helmholtz says:—“If we accept the hypothesis that elementary substances are composed of atoms, we cannot well avoid concluding that electricity also is divided into elementary portions which behave like atoms of electricity.” 1 Clerk Maxwell had already used in 1873 the phrase, “a molecule of electricity.” 2 Towards the end of the third quarter of the 19th century it therefore became clear that electricity, whatever be its nature, was associated with atoms of matter in the form of exact multiples of an indivisible minimum electric charge which may be considered to be “Nature’s unit of electricity.” This ultimate unit of electric quantity Professor Johnstone Stoney called an *electron*. 3 The formulation of electrical theory as far as regards operations in space free from matter was immensely assisted by Maxwell’s mathematical theory. Oliver Heaviside after 1880 rendered Maxwell’s work still more accessible to more compact form and by introducing greater precision into terminology (see his *Electrical Papers*, 1892). This is perhaps the place to refer also to the great services of Lord Rayleigh to electrical science. Succeeding Maxwell as Cavendish professor of physics at Cambridge in 1880, he soon devoted himself especially to the exact redetermination of the practical electrical units in absolute measure. He followed up the early work of the British Association Committee on electrical units by a fresh determination of the ohm in absolute measure, and in conjunction with other work on the electrochemical equivalent of silver and the absolute electromotive force of the Clark cell may be said to have placed exact electrical measurement on a new basis. He also made great additions to the theory of alternating electric currents, and provided fresh appliances for other electrical measurements (see his *Collected Scientific Papers*, Cambridge, 1900).

2 See Maxwell’s *Electricity and Magnetism*, vol. i. p. 350 (2nd ed., 1881).
magnetic field remained an isolated fact in electro-optics. Then M. E. Verdet (1824-1866) made a study of the subject and discovered that a solution of ferric perchloride in methyl alcohol rotated the plane of polarization in an opposite direction to heavy glass (Ann. Chim. Phys., 1854, 41, p. 370; 1855, 43, p. 37; Com. Rend., 1854, 39, p. 548). Later A. A. E. Kunt prepared metallic films of iron, nickel and cobalt, and obtained powerful negative optical rotation with them (Wied. Ann., 1884, 25, p. 515; Elect. and Mag., vol. ii, p. 100). Johnson showed that a similar effect was produced when plane polarized light was reflected from the pole of a powerful magnet (Phil. Mag., 1877, 5, 3, p. 321, and 1878, 5, p. 161). Lord Kelvin showed that Faraday's discovery demonstrated that some form of rotation was taking place along lines of magnetic force when passing through a medium. Many observers have given attention to the exact determination of Verdet's constant of rotation for standard substances, e.g. Lord Rayleigh for carbon bisulphide, and Sir W. H. Perkin for an immense range of inorganic and organic bodies.

Kerr also discovered that when certain homogeneous dielectrics were submitted to electric strain, they became birefringent (Phil. Mag., 1875, 59, pp. 337 and 446). The theory of electro-optics received great attention from Kelvin, Maxwell, Rayleigh, G. F. Fitzgerald, A. Righi and P. K. L. Drude, and experimental contributions from innumerable workers, such as F. T. Trouton, O. J. Lodge and J. L. Howard, among many others.

**Electric Waves.**—In the decade 1880-1890, the most important advance in mechanical physics was, however, that which originated with the astonishing researches of Heinrich Rudolf Hertz (1857-1894). This illustrious investigator was stimulated, by a certain problem brought to his notice by H. von Helmholtz, to undertake investigations which had for their object a demonstration of the truth of Maxwell's principle that a variation in electric displacement was in fact an electric current and had magnetic effects. It is impossible to describe here the details of these elaborate experiments; the reader must be referred to Hertz's own papers, or the English translation of them by Prof. D. E. Jones. Hertz's great discovery was an experimental realization of a suggestion made by G. F. Fitzgerald (1851-1901) in 1883 as to a method of producing electric waves in space. He invented for this purpose a radiator consisting of two metal rods placed in one line, their inner ends being provided with poles nearly touching and their outer ends with metal plates. Such an arrangement constitutes in effect a condenser, and when the two plates respectively are connected to the secondary terminals of an induction coil in operation, the plates are rapidly and alternately charged, and discharged across the spark gap with electrical oscillations (see Electrokinetics). Hertz then devised a wave detecting apparatus called a resonator. This in its simplest form consisted of a ring of wire nearly closed terminating in space. Half a wave was close together, adjustable as to distance by a micrometer screw. He found that when the resonator was placed in certain positions with regard to the oscillator, small sparks were seen between the micrometer balls, and when the oscillator was placed at one end of a room having a sheet of zinc fixed against the wall at the other end, symmetrical positions could be found in the room at which, when the resonator was there placed, either no sparks or else very bright sparks occurred according to the phase of the high tension impulses. These effects, as Hertz showed, indicated the establishment of stationary electric waves in space and the propagation of electric and magnetic force through space with a finite velocity. The other additional phenomena he observed generally contributed an all but conclusive proof of the truth of Maxwell's views. By profoundly ingenious methods Hertz showed that these invisible electric waves could be reflected and refracted like waves of light by mirrors and

ELECTRICITY.

high vacua, having been led to it by his researches on the radio-

meter. The particular details of the phenomena observed will be

found described in the article CONDUCTION, ELECTRIC (§ III.).

The main fact discovered by researches of Pickter, Hittorf and
Crookes was that in a vacuum tube containing extremely rarefied
air or other gas, a luminous discharge takes place from the ne-

gative electrode which proceeds in lines normal to the surface of
the negative electrode and renders phosphorescent both the

glass envelope and other objects placed in the vacuum tube

when it falls upon them. Hittorf made in 1869 the discovery

that solid objects could cast shadows or intercept this cathode

discharge. The cathode discharge henceforth engaged the

attention of many physicists. Varley had advanced tentatively

the hypothesis that it consisted in an actual projection of elec-

trified matter from the cathode, and Crookes was led by his re-

searches in 1870, 1871 and 1872 to embrace and confirm this

hypothesis in a modified form and announce the existence of a

fourth state of matter, which he called radiant matter, demon-

strating by many beautiful and convincing experiments that

there was an actual projection of material substance of some

kind possessing inertia from the surface of the cathode. The Ref.

German physicists such as E. Goldstein were inclined to take

another view. Sir J. J. Thomson, the successor of Maxwell and Lord

Rayleigh in the Cavendish chair at the university of Cam-

bridge, began about the year 1890 a remarkable series of

investigations on the cathode discharge, which finally enabled

him to make a measurement of the ratio of the electric charge
to the mass of the particles of matter projected from the cathode,

and to show that this electric charge was identical with the

atomic electric charge carried by a hydrogen ion in the act of

electrolysis, but that the mass of the cathode particles, or "cor

puscles" as he called them, was far less, viz. about \(\frac{1}{1836}\)th part

of the mass of a hydrogen atom. The subject was pursued

by Thomson and the Cambridge physicists with great mathem-

atical and experimental ability, and finally the conclusion

was reached that in a high vacuum tube the electric charge is

carried by particles which have a mass only a fraction, as above

mentioned, of that of the hydrogen atom, but which carry a

charge equal to the unit electric charge of the hydrogen ion as

found by electrochemical researches. 3 P. E. A. Lenard made

in 1894 (Wied. Ann. Phys., 51, p. 227) the discovery that these

cathode particles or corpuscles could pass through a window

of thin sheet aluminium placed in the wall of the vacuum tube

give rise to a class of radiation called the Lenard rays.

W. C. Röntgen of Munich made in 1896 his remarkable discovery

of the so-called X or Röntgen rays, a class of radiation produced

by the impact of the cathode particles against an impervious

metallic screen or anode plate placed in the vacuum tube. These

Röntgen rays were at once pursued by the principal

physicists in Europe during the years 1897 and 1898 and sub-

sequently. The principal property of these Röntgen rays which

attracted public attention was their power of passing through

many solid bodies and affecting a photographic plate. Hence

some substances were opaque to them and others transparent.

The astonishing feat of photographing the bones of the living

animal within the tissues soon rendered the Röntgen rays

indispensable in surgery and directed an army of investigators to

their study.

Radioactivity.—One outcome of all this was the discovery of

by H. Becquerel in 1896 that minerals containing uranium, and

particularly the mineral known as pitchblende, had the power of

affecting sensitive photographic plates enclosed in a black

paper envelope when the mineral was placed on the outside, as

2 Later results show that the mass of a hydrogen atom is not far from 1.675 \times 10^{-27} gramma and that the unit atomic charge or natural unit of electricity is 1.675 \times 10^{-19} of an electromagnetic C.G.S. unit. The mass of the electron or corpuscle is 7.2 \times 10^{-28} gramma and its diameter is 5 \times 10^{-10} centimetre. The diameter of a chemical atom is of the order of 10^{-10} centimetre. See H. A. Lorentz, "The Electron Theory," Elektrotechnische Zeitschrift, 1905, 26, p. 584; or Science Abstracts, 1905, 8, A, p. 603.
ELECTRICITY SUPPLY

The reader may be referred for an admirable summary of the theories of electricity prior to the advent of the electronic hypothesis to J. J. Thomson's "Report on Electrical Theories" (1892). In connection with the generator, it is almost an invariable custom to put down a secondary battery of storage cells, to enable the supply to be given after the engine has stopped. This is necessary, not only as a security for the continuity of supply, but because otherwise the costs of labour in running the engine night and day become excessive. The storage battery gives its supply automatically, but the dynamo and engine require incessant skilled attendance. If the building to be lighted is at some distance from the engine-house the battery should be placed in the basement of the building, and underground or overhead conductors, to convey the charging current, brought to it from the dynamo.

It is usual, in the case of electric lighting installations, to reckon all lamps in their equivalent number of 8 candle power (c.p.) incandescent lamps. In lighting a private house or building, the first thing to be done is to settle the total number of incandescent lamps and their size, whether 32 c.p., 16 c.p. or 8 c.p. Lamps of 5 c.p. can be used with advantage in small bedrooms and passages.

Each candle-power in the case of a carbon filament lamp can be taken as equivalent to 3·5 watts, or the 8 c.p. lamp as equal to 30 watts, the 16 c.p. lamp to 60 watts, and so on.

In the case of metallic filament lamps about 100 or 125 watts. Hence if the equivalent of 100 carbon filament 8 c.p. lamps is required in a building the maximum electric power-supply available must be 3000 watts or 3 kilowatts. The next matter to consider is the pressure of supply - if the battery is in position near the building to be lighted, it is best to use 100-volt incandescent lamps and enclosed arc lamps, which can be worked singly off the 100-volt circuit. If, however, the lamps are scattered over a wide area, or in separate buildings somewhat far apart, as in a college or hospital, it may be better to select 200 volts as the supply pressure.

Arc lamps can then be worked three in series with added resistance. The third step is to select the size of the dynamo unit and the amount of spare plant. It is desirable that there should be at least three dynamos, two of which are capable of taking the whole of the full load, the third being reserved to replace either of the others when required. The total power to be absorbed by the lamps and motors (if any) being given, together with an allowance for extensions, the size of the dynamos can be settled, and the power of the engines required to drive them determined. A good rule to follow is that the indicated horse power (I.H.P.) of the engine should be about one-twentieth of the dynamo full-load horse power. Also, for a 10-kilowatt dynamo an engine should be capable of giving 80 nominal (not nominal) H.P. From the I.H.P. of the engine, if a steam engine, the size of the boiler required for steam production becomes known. For small plants it is safe to reckon that, including water waste, boiler capacity should be provided equal to evaporating 40 lb. of water per hour for every I.H.P. of the engine. The locomotive boiler is a convenient form; but where large amounts of steam are required, some modification of the Lancashire boiler or the water-tube boiler is generally adopted. In settling the electromotive force of the dynamo to be employed, attention must be paid to the question of charging secondary cells, if these are used. If a secondary battery is employed in connexion with 100-volt lamps, it is usual to put in 55 or 54 cells. The electromotive force of these cells varies between 2·2 and 1·8 volts as they discharge; hence the above number of cells is sufficient for maintaining the necessary electromotive force. For charging, however, it is necessary to provide 2·5 volts per cell, and the dynamo must therefore have an electromotive force of 135 volts, plus any voltage required to overcome the fall of potential in the cable connecting the dynamo with the secondary battery. Supposing this to be 10 volts, it is safe to install dynamos having an electromotive force of 150 volts, since by means of resistance in the field circuits this electromotive force can be lowered to 110 or 100 volts required at the generator to dispose with the battery.

The size of the secondary cell will be determined by the nature

IX. 7
of the supply to be given after the dynamos have been stopped. It is usual to provide sufficient storage capacity to run all the lamps for three or four hours without assistance from the dynamo.

As an example taken from actual practice, the following figures give the plant put down to supply 500 house dynamos to a hospital. The dynamos were 15-unit machines, having a full-load capacity of 100 amperes at 190 volts, each coupled directly to an engine, with a H.P.; and a double plate of the description only, was supplied from two steel locomotive boilers, each capable of evaporating 800 lb. of water per hour. One dynamo during the day was used for charging the storage battery of 54 cells; and at night the discharge from the cells increased the current from one of the dynamos, supplying the lamps until the heaviest part of the load had been taken; after that the current was drawn from the batteries alone. In working such a layout as this it is necessary to have the means of varying the electromotive force of the dynamo as the charging of the cells proceeds. When they are nearly exhausted, their electromotive force is less than 2 volts; but as the charging proceeds, a counter-electromotive force is gradually built up, and the engineer-in-charge has to raise the voltage of the dynamo in order to maintain a constant charging current. This is effected by having the dynamos designed to give normally the highest e.m.f. required, and then inserting resistance in their field circuits to reduce it as may be necessary. The space and attendance required for an oil-engine plant are much less than for a steam-engine.

Public Supply.—The methods of constructing success in operation for public electric supply fall into two broad divisions:—(1) continuous-current systems and (2) alternating-current systems. Continuous-current systems are either low- or high-pressure.

In the former the current is generated by dynamos at some pressure less than 500 volts, generally about 400 volts, and is supplied to users at half this pressure by means of a three-wire system (see below) of distribution, with or without the addition of storage batteries.

The general arrangements of a low-pressure continuous-current supply are as follows:—If steam is the motive power selected, it is generated under all the best conditions of economy by a battery of boilers, and supplied to engines which are now almost invariably coupled direct, each to its own dynamo, on one common bedplate; a multipolar dynamo is most usually employed, coupled direct to an enclosed engine. Parsons or Curtis steam turbines (see Steam Engine) are frequently selected, since experience has shown that the costs of oil and attendance are far less for this type than for the reciprocating engine, whilst the floor space and, therefore, the building cost are greatly reduced. In choosing the size of unit to be adopted, the engineer has need of considerable experience and discretion, and also a full knowledge of the nature of the public demand for electric current. The rule is to choose as large units as possible, consistent with security, because they are proportionately more economical than small ones. The overall efficiency of a steam dynamo—that is, the ratio between the electrical power output, reckoned say in kilowatts, and the H.P. of the engine, reckoned in the same units—is a number which falls rapidly as the load decreases, but at full load may reach some such value as 80 or 85%. It is common to specify the efficiency, as above defined, which must be attained by the plant at full load, and also the efficiencies at quarter-and half-load which must be reached or exceeded. Hence in the selection of the size of the units the engineer is guided by the consideration that whatever units are in use shall be as nearly as possible fully loaded. If the demand on the station is chiefly for electric lighting, it varies during the hours of the day and night with tolerable regularity. If the output of the station, either in amperes or watts, is represented by the ordinates of a curve, the abscissae of which represent the hours of the day, this load diagram for a supply station with lighting load only, is a curve such as is shown in fig. 1, having a high peak somewhere between 6 and 8 P.M. The area enclosed by this load-diagram compared with the area of the circumscribing rectangle is called the load-factor of the station. This varies from day to day during the year, but on the average for a simple lighting load is not generally above 10 or 15%, and may be lower. Thus the total output from the station is only some 10% on an average of that at which it would be if the supply were at all times equal to the maximum demand. Roughly speaking, therefore, the total output of an electric supply station, furnishing current chiefly for electric lighting, is at best equal to about two hours' supply during the day at full load. Hence during the greater part of the twenty-four hours a large part of the plant is lying idle. It is usual to provide certain small sets of steam dynamos, called the daylight machines, for supplying the demand during the day and later part of the evening, the remainder of the machines being called into requisition only for a short time. Provision must be made for sufficient reserve of plant, so that the breakdown of one or more sets will not cripple the output of the station.

Assuming current to be supplied at about 460 volts by different and separate steam dynamos, Dy1, Dy2 (fig. 2), the machines are connected through proper amperemeters and voltmeters with omnibus bars, O1, O2, O3, on a main switchboard, so that any dynamo can be put in connection or removed. The switchboard is generally divided into three parts—one panel for the connections of the positive feeders, F1, with the positive terminals of the generators; one for the negative feeders, F2, and negative generator terminals; while from the third (or middle-wire panel) proceed an equal number of middle-wire feeders, F3. These sets of conductors are led out into the district to be supplied with current, and are there connected into a distributing system, consisting of three separate insulated conductors, D1, D2, D3, respectively called the positive, middle and negative distributing mains. The lamps in the houses, H1, H2, &c., are connected between the middle and negative, and the middle and positive, mains by smaller supply and service wires. As far as possible the numbers of lamps installed on the two sides of the system are kept equal; but since it is not possible to control the consumption of current, it becomes necessary to provide at the station two small dynamos called the balancing machines, B1, B2, connected respectively between the middle and positive and the middle and negative omnibus bars. These machines may have their shafts connected together, or they may be driven by separate steam dynamos; their function is to supply the difference in the total current circulating through the whole of the lamps respectively on the two opposite sides of the middle wire. If storage batteries are employed in the station, it is usual to install two complete batteries, S1, S2,
which are placed in a separate battery room and connected between the middle omnibus bar and the two outer omnibus bars. The extra electromotive force required to charge these batteries is supplied by two small dynamos $b_1$, $b_2$, called booster. It is not unusual to join together the two balancing dynamos and the two boosters on one common bedplate, the shafts being coupled and in line, and to employ the balancing machines as electromotors to drive the boosters as required. By the use of reversible boosters, such as those made by the Lancashire Dynamo & Motor Company under the patents of Turnbull & McLeod, having four field windings on the booster magnets (see The Electrician, 1904, p. 303), it is possible to adjust the relative duty of the dynamos and battery so that the load on the supply dynamos is always constant. Under these conditions the main engines can be worked all the time at their maximum steam economy and a smaller engine plant employed. If the load in the station rises above the fixed amount, the batteries discharge in parallel with the station dynamos; if it falls below, the batteries are charged and the station dynamos take the external load.

The general arrangements of a low-pressure supply station are shown in figs. 3 and 4. It consists of a boiler-house containing a bank of boilers, either Lancashire or Babcock & Wilcox being generally used (see Boiler), which furnish steam to the engines.

From The Electrician.

Figs. 3 and 4.—Low-pressure Supply Station.
and dynamos, provision being made by duplicate steam-pipes or a ring main so that the failure of a single engine or dynamo does not cripple the whole supply. The furnace gases are taken through an economizer (generally Green’s) so that they give up their heat to the cold feed water. If condensing water is available the engines are worked condensing, and this is an essential condition of economy when steam turbines are employed. Hence, either a condensing water pond or a cooling tower has to be provided to cool the condensing water and enable it to be used over and over again. Preferably the station should be situated near a river or canal and a railway siding. The steam dynamos are generally arranged in an engine-room so as to be overlooked from a switchboard gallery (fig. 3), from which all the control is carried out. The boiler furnaces are usually stoked by automatic stokers. Owing to the relatively small load factor (say 8 or 10%), a station giving electric supply for lighting only, the object of every station engineer is to cultivate a demand for electric current for power during the day-time by encouraging the use of electric motors for lifts and other purposes, but above all to create a demand for traction purposes. Hence most urban stations now supply current not only for electric lighting but for running the town tramway system, and this traction load being chiefly a daylight load serves to keep the plant employed and remunerative. It is usual to furnish a continuous current supply for traction at 500 or 600 volts, although some station engineers are advocating the use of higher voltages. In those stations which supply current for traction, but which have a widely scattered lighting load, double current dynamos are often employed, furnishing from one and the same armature a continuous current for traction purposes, and an alternating current for lighting purposes.

In some places a high voltage system of electric supply by continuous current is adopted. In this case the current is generated at a pressure of 1000 or 2000 volts, and transmitted from the generating station by conductors, or transformer centres, which are either buildings above ground or cellars or excavations under the ground. In these transformer centres are placed machines, called continuous-current transformers, which transform the electric energy and create a secondary electric current at a lower pressure, perhaps 100 or 150 volts, to be supplied by distributing mains to users (see Transformers). From these sub-centres insulated conductors are run back to the generating station, by which the engineer can start or stop the continuous-current rotatory transformers, and at the same time inform himself as to their proper action and the electromotive force at the secondary terminals. This system was first put in practice in Oxford, England, and hence has been sometimes called by British engineers “the Oxford system.” It is now in operation in a number of places in England, such as Wolverhampton, Walsall, and Shoreditch in London. It has the advantage that in connection with the low-pressure distributing system secondary batteries can be employed, so that a storage of electric energy is effected. Further, continuous-current arc lamps can be worked in series off the high-pressure mains, that is to say, sets of 20 to 40 arc lamps can be operated for the purpose of street lighting by means of the high-pressure continuous current.

The alternating current systems in operation at the present time are the single-phase system, with distributing transformers or transformer sub-centres, and the polyphase systems, in which the alternating current is transformed down into an alternating current on the sub-centres or, as worked in railway transformers, into a continuous current.

The general arrangement of a single-phase alternating-current system is as follows: The generating station contains a number of alternators, A₁ A₂ (fig. 5), producing single-phase alternating current, either at 1000, 2000, or sometimes, as at Deptford and other places, 10,000 volts. This current is distributed from the station either at the pressure at which it is generated, or after being transformed up to a higher pressure by the transformer T. The alternators are sometimes worked in parallel, that is to say, all furnish their current to two common omnibus bars on a high-pressure switchboard, and each is switched into circuit at the moment when it is brought into step with the other machines, as shown by some form of phase-indicator. In some cases, instead of the high-pressure feeders starting from omnibus bars, each alternator works independently and the feeders are grouped together on the various alternators as required. A number of high-pressure feeders are carried from the main switchboard to various transformer sub-centres or else run throughout the district to which current is to be furnished. If the system laid down is the transformer sub-centre system, then at each of these sub-centres is placed a battery of alternating-current transformers, T₁ T₂ T₃, having their primary circuits all joined in parallel to the terminals of the high-pressure feeders, and their secondary circuits all joined in parallel on a distributing main, suitable switches and cut-outs being interposed. The pressure of the current is then transformed down by these transformers to the required supply pressure. The secondary circuits of these transformers are generally provided with three terminals, so as to supply the low-pressure side on a three-wire system. It is not advisable to connect together directly the secondary circuits of all the different sub-centres, because then a fault or short circuit on one secondary system affects all the others. In banking together transformers in this manner in a sub-station it is necessary to take care that the transformation ratio and secondary drop (see Transformers) are exactly the same; otherwise one transformer will take more than its full share of the load and will become overheated. The transformer sub-station system can only be adopted where the area of supply is tolerably compact. Where the consumers lie scattered over a large area, it is necessary to carry the high-pressure mains throughout the area, and to place a separate transformer or transformers in each building. From a financial point of view, this “house-to-house system” of alternating-current supply, generally speaking, is less satisfactory in results than the transformer sub-centre system. In the latter case, all the transformers can be switched off, either by hand or by automatic apparatus, during the time when the load is light, and then no power is expended in magnetizing their cores. But with the house-to-house system the whole of the transformers continually remain connected with the high-pressure circuits; hence in the case of supply stations which have only an ordinary electric-lighting load, and therefore a load-factor not above 10%, the efficiency of distribution is considerably diminished.

The single-phase, alternating-current system is defective in that it cannot be readily combined with secondary batteries for the storage of electric energy. Hence in many places preference is now given to the polyphase system. In such a system a poly-phase alternating current, either two- or three-phase, is transmitted from the generating station at a pressure of 5000 to 10,000 volts, or sometimes higher, and at various sub-stations is transformed down, first by static transformers into an alternating current of lower pressure, say 500 volts, and then by
ELECTRICITY SUPPLY

means of rotatory transformers into a continuous current of 500 volts or lower for use for lighting or traction.

In the case of large cities such as London, New York, Chicago, Berlin and Paris the use of small supply stations situated in the interior of the city has gradually given way to the establishment of large supply stations outside the area; in these alternating current is generated on the single or polyphase system at a high voltage and transmitted by underground cables to sub-stations in the city, at which it is transformed down for distribution for private and public electric lighting and for urban electric traction.

Owing to the high relative cost of electric power when generated in small amounts and the great advantages of generating it in proximity to coal mines and waterfalls, the supply of electric power in bulk to small towns and manufacturing districts has become a great feature in modern electrical engineering. In Great Britain, where there is little useful water power but abundance of coal, electric supply stations for supply in bulk have been built in the coal-producing districts of South Wales, the Midlands, the Clyde valley and Yorkshire. In these cases the current is a polyphase current generated at a high voltage, 3000 to 10,000 volts, and sometimes raised again in pressure to 20,000 volts and transmitted in overhead lines to the districts to be supplied. It is there reduced in voltage by transformers and employed as an alternating current, or is used to drive polyphase motors coupled to direct current generators to reproduce the power in continuous current form. It is then distributed for local lighting, street or railway traction, driving motors, and metallurgical or electro-chemical applications.

Experience has shown that it is quite feasible to distribute in all directions for 25 miles round a high-pressure generating station, which thus supplies an area of nearly 2000 sq. m. At such stations, employing large turbine engines and alternators, electric power may be generated at a works cost of 0.35d. per kilowatt (K.W.), the coal cost being less than 0.12d. per K.W., and the selling price to large load-factor users not more than 0.5d. per K.W. The average price of supply from the local generating stations in towns and cities is from 3d. to 4d. per unit, electric energy for power and heating being charged at a lower rate than that for lighting only.

We have next to consider the structure and the arrangement of the conductors employed to convey the currents from their place of creation to that of utilization. The conductors themselves for the most part consist of copper having a conductivity of not less than 98% according to Matthiessen's standard. They are distinguished as (1) External conductors, which are a part of the public supply and belong to the corporation or company supplying the electricity; (2) Internal conductors, housed-wire or glass-covered wire, part of the system of the house or building supplied and usually the property of its owner.

The external conductors may be overhead or underground. Overhead conductors may consist of bare stranded copper cables carried on porcelain insulators mounted on stout iron or wooden poles. If the current is a high-pressure one, these insulators must be carefully tested, and are preferably of the pattern known as oil insulators.

In and near towns it is necessary to employ insulated overhead conductors, generally india-rubber-covered stranded copper cables, suspended by leather loops from steel bearer wires which take the weight. The British Board of Trade have issued elaborate rules for the construction of overhead lines to transmit large electric currents. Where telephone and telegraph wires pass over such overhead electric lighting wires, they have to be protected from falling on the latter by means of guard wires.

By far the largest part, however, of the external electric distribution is now carried out by underground conductors, which are either bare or insulated. Bare copper conductors may be carried underground in culverts or chases, air being in this case the insulating material, as in the overhead system. A culvert and covered chase is constructed under the road or side-walk, and properly shaped oak crossbars are placed in it carrying glass or porcelain insulators, on which stranded copper cables, or, preferably, copper strips placed edgeway, are stretched and supported. The advantages of this method of construction are cheapness and the ease with which connexions can be made with service-lines for house supply; the disadvantages are the somewhat large space in which coal-gas leaking out of gas-pipes can accumulate, and the difficulty of keeping the culverts all times free from rain-water. Moisture has a tendency to collect on the negative insulators, and hence to make a dead earth on the negative side of the main; while unless the culverts are well ventilated, explosions from mixtures of coal-gas and air are liable to occur. Insulated cables are insulated either with a material which is in itself waterproof, or with one which is only waterproof in so far as it is enclosed in a waterproof tube, e.g. of lead. Gutta-percha and india-rubber are examples of materials of the former kind. Gutta-perchas, although practically everlasting when in darkness and laid under water, as in the case of submarine cables, has not been found satisfactory for use with large systems of electric distribution, although much employed for telephone and telegraph work. Insulated underground external conductors are of three types:—

(a) Insulated Cables drawn into Pipes.—In this system of distribution cast-iron or iron and lead pipes, or other similar tubing made of a material called bitumen concrete, are first laid underground in the street. These contain a number of holes or "ways," and at intervals drawing-in boxes are placed which consist of a brick or cast-iron box having a water-tight lid, by means of which access is gained to a certain section of the conduit. Wires are used to draw in the cables, which are covered with either india-rubber or lead, the copper being insulated by means of paper, impregnated jute, or other similar material. The advantages of a drawing-in system are that spare ways can be left when the conduits are put in, so that at a future time fresh cables can be added without breaking up the roadway. (b) Cables in Bitumen.—One of the earliest systems of distribution employed by T. A. Edison consisted in fixing two segment-shaped copper conductors in a steel tube, the interspace between the conductors and the tube being filled in with a bitumen compound. A later plan is to lay down an iron trough, in which the cables are supported by wooden bearers at proper distances, and fill in the whole with natural bitumen. This system has been carried out extensively by the Callendar Cable Company. Occasionally concentric lead-covered and armoured cables are laid in this way, and then form an expensive but highly efficient form of insulated conductor. In selecting a system of distribution regard must be paid to the nature of the soil in which the cables are laid. Lead is easily attacked by soft water, although under some conditions it is apparently exceedingly durable, and an atmosphere containing hydrogen is injurious to lead. Armoured cables are laid in very extensively used system of distribution armoured cables are employed. In this case the copper conductors, two, three or more in number, may be twisted together or arranged concentrically, and insulated by means of specially prepared jute or paper insulation, overlaid with a continuous tube of lead. Over the lead, but separated by a hemp covering, is put a steel armour consisting of two layers of steel strip, wound in opposite directions and kept in place by an external covering. Such a cable can be laid directly in the ground without any preparation other than the excavation of a simple trench, junction-boxes being inserted at intervals to allow of branch cables being taken off. The armoured cable used is generally of the concentric pattern (fig. 6). It consists of a stranded copper cable composed of a number of wires twisted together and overlaid with an insulating material. Outside this a tubular arrangement of copper wires and a second layer of insulation, and finally a protective covering of lead and steel wires by which the armour is placed. In some cases three concentric cylindrical conductors are formed by twisting wires or copper strips with insulating material between. In others two or three cables of stranded copper are embedded in insulating material and included in a lead sheath. This last type of cable is usually called a two- or three-core pattern cable (fig. 7).
The arrangement and nature of the external conductors depends on the system of electric supply in which they are used. In the case of continuous-current supply for incandescent electric lighting and motive power in small units, when the external conductors are laid down on the three-wire system, regulations which, if followed, are a safeguard against bad workmanship and resulting possibility of damage by fire. Where fires having an electric origin have taken place, they have invariably been traced to some breach of these rules. Opinions differ, however, as to the value and security of this method of laying interior conductors in buildings, and two or three alternative systems have been employed. One of these, called the interior conduit system, highly insulating waterproof and practically fireproof tubes or conduits replace the wooden casing; these, being either of plain insulating material, or covered with brass or steel armour, may be placed under plaster or against walls. They are connected by bends or joint-boxes. The insulated wires being drawn into them, any short circuit or heating of the wire cannot give rise to a fire, as it can only take place in the interior of a non-inflammable tube. A third system of electric light wiring is the safety concentric system, in which concentric conductors are used. The inner one, which is well insulated, consists of a copper-stranded cable. The outer may be a galvanized iron strand, a copper tape or braid, or a brass tube, and is therefore necessarily connected with the earth. A fourth system consists in the employment of twin insulated wires twisted together and sheathed with a lead tube; the conductors thus formed can be fastened by staples against walls, or laid under plaster or floors.

The general arrangement for distributing current to the different portions of a building for the purpose of electric lighting is to run up one or more rising mains, from which branches are taken off to distributing boxes on each floor, and from these boxes to carry various branch circuits to the lamps. At the distributing boxes are collected the cut-outs and switches serving the various circuits. When alternating currents are employed, it is usual to select as a type of conductor either twin-twisted conductor or concentric; and the employment of these types of cable, rather than two separate cables, is essential in any case where there are telephone, or telegraph wires in proximity, for otherwise the alternating current would create inductive disturbances in the telephone circuit. The house-wiring also comprises the details of switches for controlling the lamps, cut-outs or fuses for preventing an excess of current passing, and fixtures or supports for lamps of an ornamental character. For the details of these, special treatises on electric interior wiring must be consulted.

II. Commercial Aspects.—To enable the public supply enterprise referred to in the foregoing section to be carried out in England, statutory powers became necessary to break up the streets. In the early days a few small stations were established for the supply of electricity within "block" buildings, or by means of overhead wires within restricted areas, but the limitators proved uneconomical and the installations were for the most part merged into larger undertakings sanctioned by parliamentary powers. In the year 1879 the British government had its attention directed for the first time to electric lighting as a possible subject for legislation, and the consideration of the then existing state of electric lighting was referred to a select committee of the House of Commons. No legislative action, however, was taken at that time. In fact the invention of the incandescent lamp was incomplete—Edison's British master-patent was only filed in Great Britain in November 1879. In 1881 and 1882 electrical exhibitions were held in Paris and at the Crystal Palace, London, where the improved electric
incandescent lamp was brought before the general public. In 1882 parliament passed the first Electric Lighting Act, and considerable speculation ensued. The aggregate capital of the companies registered in 1882–1883 to carry out the public supply of electricity in Great Britain amounted to £15,000,000, but the onerous conditions of the act deterred investors from proceeding with the enterprise. Not one of the sixty-two provisional orders granted to companies in 1883 under the act was carried out. In 1884 the Board of Trade received only four applications for provisional orders, and during the subsequent four years only one order was granted. Capitalists declined to go on with a business which if successful could be taken from them by local authorities at the end of twenty-one years upon terms of paying only the then value of the plant, lands and buildings, without regard to past or future profits, goodwill or other considerations. The electrical industry in Great Britain ripened at a time when public opinion was averse to the creation of further monopolies, the general belief being that railway, water and gas companies had in the past received valuable concessions on terms which did not sufficiently safeguard the interests of the community. The great development of industries by means of private enterprise in the early part of the 19th century produced a reaction which in the latter part of the century had the effect of discouraging the creation by private enterprise of undertakings partaking of the nature of monopolies; and at the same time efforts were made to strengthen local and municipal institutions by investing them with wider functions. There were no fixed principles governing the relations between the state or municipal authorities and commercial companies rendering monopoly services. The new conditions imposed on private enterprise for the purpose of safeguarding the interests of the public were very tentative, and a former permanent secretary of the Board of Trade has stated that the efforts made by parliament in these directions have sometimes proved injurious alike to the public and to investors. One of these tentative measures was the Tramways Act 1879, and twelve years later it was followed by the first Electric Lighting Act.

It was several years before parliament recognized the harm that had been done by the passing of the Electric Lighting Act 1882. A select committee of the House of Lords sat in 1886 to consider the question of reform, and as a result the Electric Lighting Act 1888 was passed. This amending act altered the period of purchase from twenty-one to forty-two years, but the terms of purchase were not materially altered in favour of investors. The act, while stipulating for the consent of local authorities to the granting of provisional orders, gives the Board of Trade power in exceptional cases to dispense with the consent, but this power has been used very sparingly. The right of vetoing an undertaking, conferred on local authorities by the Electric Lighting Acts and also by the Tramways Act 1879, has frequently been made use of to exact unduly onerous conditions from promoters, and has been the subject of complaint for years. Although, in the opinion of ministers of the Crown, the exercise of the veto by local authorities has on several occasions led to considerable scandals, no government has so far been able, owing to the very great power possessed by local authorities, to modify the law in this respect. After 1888 electric lighting went ahead in Great Britain for the first time, although other countries where legislation was different had long previously enjoyed its benefits. The developments proceeded along three well-defined lines. In London, where none of the gas undertakings was in the hands of the authorities, the majority of the districts were allotted to companies, and competition was permitted between two and sometimes three companies. In the provinces the cities and larger towns were held by the municipalities, while the smaller towns, in cases where consents could be obtained, were left to the enterprise of companies. Where consents could not be obtained these towns were for some time left without supply.

Some statistics showing the position of the electricity supply business respectively in 1896 and 1906 are interesting as indicating the progress made and as a means of comparison between these two periods of the state of the industry as a whole. In 1896 thirty-eight companies were at work with an aggregate capital of about £2,000,000, and thirty-three municipalities with electric lighting loans of nearly £2,000,000. The figures for 1906, ten years later, show that 187 electricity supply companies were in operation with a total investment of close on £32,000,000, and 277 municipalities with loans amounting to close on £36,000,000. The average return on the capital invested in the companies at the last saddled was about 8½. The main divisions of the average expenditure are:

The load connected, expressed in equivalents of eight candle-power lamps, was 2,000,000 in 1896 and 24,000,000 in 1906. About one-third of this load would be for power purposes and about two-thirds for lighting. The Board of Trade units sold were 30,200,000 in 1896 and 333,000,000 in 1906, and the average prices per unit obtained were 7½d. and 2½d. respectively, or a revenue of £7,120,000 in 1896 and over £2,000,000 in 1906. The working expenses per Board of Trade unit sold, excluding depreciation, sinking fund and interest were as follows:

The economics of electric lighting were at first assumed to be similar to those of gas lighting. Experience, however, soon proved that there were important differences, one being that gas may be stored in gasometers without appreciable loss and the work of production can be continued on steadily without reference to fluctuations of demand. Electricity cannot be economically stored to the same extent, and for the most part it has to be used as it is generated. The demand for electric light is practically confined to the hours between sunset and midnight, and it rises sharply to a "peak" during this period. Consequently the generating station has to be equipped with plant of sufficient capacity to cope with the maximum load, although the peak does not persist for many minutes—a condition which is very uneconomical both as regards capital expenditure and working costs (see LIGHTING: Electric).

In order to obviate the unproductiveness of the generating plant during the greater part of the day, electricity supply undertakings sought to develop the "daylight" load. This they did by supplying electricity for traction purposes, but more particularly for industrial power purposes. The difficulties in the way of this line of development, however, were that electric power could not be supplied cheaply enough to compete with steam, hydraulic, gas and other forms of power, unless it was generated on a very large scale, and this large demand could not be developed within the restricted areas for which provisional orders were granted and under the restrictive conditions of these orders in regard to situation of power-house and other matters.

The leading factors which make for economy in electricity supply are the magnitude of the output, the load factor, and
the diversity factor, also the situation of the power house, the means of distribution, and the provision of suitable, trustworthy and efficient plant. These factors become more favourable the larger the area and the greater and more varied the demand to be supplied. Under the special conditions of the legislative clauses, the cost per unit diminishes, but the ratio (called the load factor) which the output during any given period bears to the maximum possible output during the same period has a very important influence on costs. The ideal condition would be when a power station is working at its normal maximum output continuously night and day. This would give a load-factor of 100%, and represents the ultimate ideal towards which the electrical engineer strives by increasing the area of his output, and consequently also the load and the variety of the overlapping demands. It is only by combining a large number of demands which fluctuate at different times—that is by achieving a high diversity factor—that the supplier of electricity can hope to approach the ideal of continuous and steady output. Owing to the dovetailing of miscellaneous demands the actual demand on a power station at any moment is never anything like the aggregate of all the maximum demands. One large station would require a plant of 36,000 k.w. capacity if all the demands came upon the station simultaneously, but the maximum demand on the generating plant is only 15,000 kilowatts. The difference between these two figures may be taken to represent the economy effected by combining a large number of demands on one station. In short, the keynote of progress in cheap electricity is increased and diversified demand combined with concentration of load. The average load-factor of all the British electricity stations in 1907 was 13.5%—a figure which tends to improve.

Several electric power supply companies have been established in the United Kingdom to give practical effect to these principles.

The Electric Lighting Acts, however, do not provide for the establishment of large power companies, and special acts of parliament have had to be passed to authorize these undertakings. In 1898 several bills were introduced in parliament for these purposes. They were referred to a joint committee of both Houses of Parliament presided over by Lord Cross. The committee concluded that, where sufficient public advantages are shown, powers should be given for the supply of electricity over areas including the districts of several local authorities and involving the use of exceptional plant; that the usual conditions of purchase of the undertakings by the local authorities did not apply to such undertakings; that the period of forty-two years was not applicable to these undertakings; that terms of purchase should be reconsidered. With regard to the provision of the Electric Lighting Acts which requires that the consent of the local authority should be obtained as a condition precedent to the granting of a provisional order, the committee was of opinion that the local authority should be entitled to be heard by the Board of Trade, but should not have the power of veto. No general legislation took place as a result of these recommendations, but the undermentioned special acts constituting power supply companies were passed.

In 1902 the president of the Board of Trade stated that a bill had been drafted which he thought "would go far to meet all the reasonable objections that had been urged against the present powers by the local authorities." In 1904 the government introduced the Supply of Electricity Bill, which provided for the removal of some of the minor anomalies in the law relating to electricity. The bill passed through all its stages in the House of Lords but was not proceeded with in the House of Commons. In 1905 the bill was again presented to parliament but allowed to lie on the table. In the words of the president of the Board of Trade, there was "difficulty of dealing with this question so long as local authorities took so strong a view as to the power which ought to be reserved to them in connexion with this enterprise." In the official language of the council of the Institution of Electrical Engineers, the development of electrical science in the United Kingdom is in a backward condition as compared with other countries in respect of the practical application to the industrial and social requirements of the nation, notwithstanding that Englishmen have been among the first in inventive genius. The cause of such backwardness is largely due to the conditions under which the electrical industry has been carried on in the country, and especially to the restrictive legislation and the great expense of obtaining the necessary power and traction undertakings, and to the powers of obstruction granted to local authorities. Eventually The Electric Lighting Act 1909 was passed. This Act provides—

(i) for the granting of provisional orders authorizing any local authority or company to supply electricity in bulk; (ii) for the exercise of electric lighting powers by local authorities jointly under provisional order; (iii) for the supply of electricity to railways and tramways outside the area of supply with the consent of the Board of Trade; (iv) for the compulsory acquisition of land for generating stations by provisional order; (v) for the exemption of agreements for the supply of electricity from stamp duty; and (vi) for the amendment of regulations relating to July notices, revision of maximum price, certification of meters, transfer of powers of undertakers, auditors' reports, and other matters.

The first of the Power Bills was promoted in 1898, under which it was proposed to erect a large generating station in the Midlands from which the area of about two thousand square miles would be supplied. Vigorous opposition was organized against the bill by the local authorities and it did not pass. The bill was revived in 1899, but was finally crushed. In 1900 and following years several power bills were successfully promoted, and the following are the areas over which the powers of these acts extend:

In Scotland, (1) the Clyde Valley, (2) the River Clyde, (3) the districts described as "Scottish Central," comprising Linlithgow, Clackmannan, and portions of Dumfart and Stirling, and (4) the Lothians, which include portions of Midlothian, East Lothian, Peebles and Lanark.

In England there are companies operating in (1) Northumberland, (2) Durham county, (3) Lancashire, (4) South Wales and Carmarthenshire, (5) Derbyshire and Nottinghamshire, (6) Leicester and Warwickshire, (7) Yorkshire, (8) Shropshire, Worcestershire and Staffordshire, (9) Somerset, (10) Kent, (11) Cornwall, (12) portions of Gloucestershire, (13) North Wales, (14) North Staffordshire, Derbyshire, Denbighshire and Flintshire, (15) West Cumberland, (16) the Cleveland district, (17) the North Metropolitan district, and (18) the West Metropolitan area. An undertaking which may be included in this category, although it is not a Power Act company, is the Midland Electric Corporation in South Staffordshire. The systems of generation and distribution are generally 10,000 or 11,000 volts three-phase alternating current.

The powers conferred by these acts were much restricted as a result of opposition offered to them. In many cases the larger towns were cut out of the areas of supply altogether, but the general rule was that the power company was prohibited from supplying direct to a power consumer in the area of an authorized distributor without the consent of the latter, subject to appeal to the Board of Trade. Even this restricted power of direct supply was not embodied in all the acts, the power of taking supply in bulk being left only to certain authorized distributors and to authorized users such as railways and tramways. Owing chiefly to the exclusion of large towns and industrial centres from their areas, these power supply companies did not all prove as successful as was expected.

In the case of one of the power companies which has been in a favourable position for the development of its business, the theoretical conclusions in regard to the economy of large production above stated have been amply demonstrated in practice. In 1901, when this company was emerging from the stage of a simple electric lighting company, the total costs per unit were 1.05d., with an output of about 2½ million units per annum. In 1905 the output rose to over 30 million units mostly for power and traction purposes, and the costs fell to 0.56d. per unit.

An interesting phase of the power supply question has arisen in London. Under the general acts it was stipulated that the power-house should be erected within the area of supply, and
amalgamation of undertakings was prohibited. After less than a decade of development several of the companies in London found themselves obliged to make considerable additions to their generating plants. But their existing buildings were full to their utmost capacity, and the difficulties of generating cheaply on crowded sites had increased instead of diminished during the interval. Several of the companies had to promote special acts of parliament to obtain relief, but the idea of a general combination was not considered to be within the range of practical politics until 1905, when the Administrative Committee of the London Electric Power Bill was introduced. Compared with other large cities, the consumption of electricity in London is small. The output of electricity in New York for all purposes is 971 million units per annum or 282 units per head of population. The output of electricity in London is only 42 units per head per annum. There are in London twelve local authorities and fourteen companies carrying on electricity supply undertakings. The capital expenditure is £5,127,000 by the local authorities and £12,430,000 by the companies, and their aggregate capacity of plant is 169,000 k.w. The total output is about 160,000,000 units per annum, the total revenue is over £2,000,000, and the gross-profit before providing for interest and sinking fund charges is £1,158,000. The general average cost of production is 1-5d. per unit, and the average price per unit sold is 3-16d., but some of the undertakers have already supplied electricity to large consumers at 6d. per k.w., and one company has reduced the rate to 4d. per k.w. By generating on a large scale for a wide variety of demands the promoters of the new scheme calculated to be able to offer electrical energy in bulk to electricity supply companies and local authorities at prices substantially below their costs of production at separate stations, and also to provide them and power users with electricity at rates which would compete with other forms of power. The authorised capital was fixed at £6,666,000, and the initial outlay for the first plant was estimated at £3,000,000. The costs of generating power were estimated at 2d. per unit, and the total cost at 0-5d. per unit sold. The output by the year 1901 was estimated at 133,500,000 units at an average-sellling price of 0-7d. per unit, to be reduced to 0-5d. by 1916 when the output was estimated at 600,000,000 units. The bill underwent a searching examination before the House of Lords committee and was passed in an amended form. At the second reading in the House of Commons a strong effort was made to throw it out, but it was allowed to go to committee. The committee was asked to refer the undertaking to the Board of Trade. The company is bound to supply authorities and undertakers upon receiving notice and upon the applicants agreeing to pay for at least seven years an amount sufficient to yield 20% on the outlay (excluding generating plant or wires already installed). Other persons to whom the company is authorized to supply may require it upon terms to be settled, if not agreed, by the Board of Trade. Dividends are usually restricted to 8%, with a provision that the rate may be increased upon the average price charged being reduced. The maximum charges are usually limited to 3d. per unit for any quantity up to 400 hours' supply, and 2d. per unit beyond. No preference is to be shown between consumers in like circumstances. Many provisions of the general Electric Lighting Acts are excluded from these special acts, in particular the clause giving the local authority the right to purchase the undertaking compulsorily.

B. Licence.—The only advantages of proceeding by licence are that it can be expeditiously obtained and does not require confirmation by parliament; but some of the provisions usually inserted in provisional orders would be ultra vires in a licence, and the Electric Lighting Clauses Act 1899 does not extend to licences. The term of a licence does not exceed seven years, but is renewable. The consent of the local authority is necessary even to an application for a licence. None of the licences that have been granted is now in force.

C. Provisional Order.—An intending applicant for a provisional order must serve the local authority with notice of his intention on every local authority within the proposed area of supply on or before the 1st of July prior to the session in which application is to be made to the Board of Trade. This provision has given rise to much complaint, as it gives the local authorities a long time for bargaining.
and enables them to supersede the company's application by themselves applying for provisional orders. The Board of Trade generally give preference to the applications of local authorities.

In 1905 the Board of Trade issued a memorandum stating that, in view of the revocation of a large number of provisional orders which had been obtained by local authorities, and in view of the agreements into which local authorities had entered into agreements with companies for carrying the orders into effect (which agreements were in many cases ultra vires or at least of doubtful validity), it appeared undesirable that a local authority should apply for a provisional order without having a definite intention of exercising the powers, and that in future the Board of Trade would not grant an order to a local authority unless the board were satisfied that the powers would be exercised within a specified period.

Every undertaking authorized by provisional order is subject to the provision of the general act entitling the local authority to purchase compulsorily at the end of forty-two years (or shorter period), or after the expiration of every subsequent period of ten years (unless varied by agreement between the parties with the consent of the Board of Trade), so much of the undertaking as is within the jurisdiction of the purchasing authority upon the terms of paying the then value of all lands, buildings, works, materials and plant, suitable to and used for the purposes of the undertaking; provided that the value of such lands, &c., shall be deemed to be their fair market value at the time of purchase, due regard being had to the nature and then condition and state of repair thereof, and to the circumstance that they are in such positions as to be ready for immediate working, and to the suitability of the same to the purposes of the undertaking, and where a part only of the undertaking is purchased, to any loss occasioned by severance, but without any addition in respect of compulsory purchase or of goodwill, or of any profits which may or might have been or be made from the undertaking or any similar consideration. Subject to this right of purchase by the local authority, a provisional order (but not a licence) may be for such period as the Board of Trade may think proper, but so far no limit has been imposed, and unless purchased by a local authority the powers are held in perpetuity.

No monopoly is granted to undertakers, and since 1889 the policy of the Board of Trade has been to sanction two undertakings in the same metropolitan area, preferably using different systems, but to discourage competing schemes within the same area in the provinces. Undertakers must within two years lay mains in certain specified streets. After the first eighteen months they may be required to lay mains in other streets upon conditions specified in the order, and any owner or occupier of premises within 50 yds. of a distributing main may require the undertakers to take steps to supply to him, but the consumer must pay the cost of the lines laid upon his property and of so much outside as exceeds 60 ft. from the main, and he must also contract for two and in some cases for three years' supply. But undertakers are prohibited in making agreements for supply from showing any undue preference. The maximum price in London is 135. ad. per quarter for any quantity up to 20 units, and beyond that 8d. per unit, but 12s. 8d. per quarter up to 20 units and 7d. per unit beyond is the more general maximum. The "Bermondsey clause" requires the undertakers (local authority) so to fix their charges (not exceeding the specified maximum) that the revenue shall not be less than the expenditure.

There is no statutory obligation on municipalities to provide for depreciation of electricity supply undertakings, but after providing for all expenses, interest on loans, and sinking fund instalments, the local authority may allow interest fully, or in part, upon the aggregate capital expenditure. Any deficiency when not met out of reserve is payable out of the local rates.

The principle on which the Local Government Board sanctions municipal loans for electric lighting undertakings is that the period of the loan shall not exceed the life of the works, and that future ratepayers shall not be unduly burdened. The periods of the loans vary from ten years for accumulators and arc lamps to sixty years for lands. Within the county of London the loans raised by the metropolitan borough councils for electrical purposes are sanctioned by the London County Council, and that body allows a minimum period of twenty years for repayment. Up to 1904-1905, 245 loans had been granted by the council, and the average period was 21 years.

In 1901 the Institution of Civil Engineers appointed a committee to consider the advisability of standardizing various kinds of iron and steel sections. Subsequently the original reference was enlarged, and in 1902 the Institution of Electrical Engineers was invited to co-operate. The treasury, as well as railway companies, manufacturers and others, have made grants to defray the expenses. The committee on electrical plant has ten sub-committees. In August 1904 an interim report was issued by the sub-committee on generators, motors and transformers, dealing with pressures and frequencies, rating of generators and motors, direct-current generators, alternating-current generators, and motors.

In 1903 the specification for British standard tramway rails and fish-plates was issued, and in 1904 a standard specification for tubular tramway poles was issued. A sectional committee was formed in 1904 to correspond with foreign countries with regard to the formation of an electrical international commission to study the question of an international standardization of nomenclature and ratings of electrical apparatus and machinery.

The electrical manufacturing branch, which is closely related to the electricity supply and other operating departments of the electrical industry, only dates from about 1880. Since that time it has undergone many vicissitudes. It began with the manufacture of small arc lighting equipment for railway stations, streets and public buildings. When the incandescent lamp became a commercial article, ship-lighting sets and installations for theatres and mansions constituted the major portion of the electrical work. The next step was the organization of house-to-house distribution of electricity from small "central stations," ultimately leading to the comprehensive public supply in large towns, which involved the manufacture of generating and distributing plants of considerable magnitude and complexity. With the advent of electric traction about 1866, special machinery had to be produced, and at a later stage the manufacturer had to solve problems in connexion with bulk supply in large areas and for power purposes. Each of these main departments involved changes in ancillary manufactures, such as cables, switches, transformers, meters, &c., so that the electrical manufacturing industry has been in a constant state of transition. At the beginning of the period referred to Germany and America were followed by the lead of England in theoretical developments, and for some time Germany obtained electrical machinery from England. Now scarcely any electrical apparatus is exported to Germany, and considerable imports are received by England from that country and America. The explanation is to be found mainly in the fact that the adverse legislation of 1885 had the effect of restricting enterprise, and while British manufacturers were compulsorily inert during periods of impeded growth of the two most important branches of the industry—electric lighting and traction—manufacturers in America and on the Continent of Europe, who were in many ways encouraged by their governments, devoted their resources to the establishment of factories and electrical undertakings, and to the development of efficient selling organizations at home and abroad. When after the amendment of the adverse legislation in 1888 a demand for electrical machinery arose in England, the foreign manufacturers had to aggregate to 4,000 on a large scale, and were further aided by fiscal conditions to undersell English manufacturers, not only in neutral markets, but even in their own country. Successful manufacture on a large scale is possible only by standardizing the methods of production. English manufacturers were not able to standardize because they had not the necessary output. There had been no repetitive demand, and there was no production on a large scale. Foreign manufacturers, however, were able to standardize by reason of the

large uniform demand which existed for their manufactures. Statistics are available showing the extent to which the growth of the electrical manufacturing industry in Great Britain was delayed. Nearly twenty years after the inception of the industry there were only twenty-four manufacturing companies registered in the United Kingdom, having an aggregate subscribed capital of under £7,000,000. But in 1907 there were 292 companies with over £42,000,000 subscribed capital. The cable and incandescent lamp sections show that when the British manufacturers were allowed opportunities they are not slow to take advantage of them. The cable-making branch was established under the more encouraging conditions of the telegraph industry, and the lamp industry was in the early days protected by patents. Other departments not susceptible to foreign competition on account of freights, such as the manufacture of storage batteries and rolling stock, are also fairly prosperous. In departments where special circumstances offer a prospect of success, the technical skill, commercial enterprise and general efficiency of British manufacturers manifest themselves by positive progress and not merely by the continuance of a struggle against adverse conditions. The normal posture of the British manufacturer of electrical machinery has been described as one of desperate defence of his home trade; that of the foreign manufacturer as one of vigorous attack upon British and other open markets. In considering the position of English manufacturers compared with their foreign rivals, some regard should be had to the patent laws. One condition of a grant of a patent in most foreign countries is that the patent shall be worked in those countries within a specified period. But a foreign inventor was until 1907 able to secure patent protection in Great Britain without any obligation to manufacture there. The effect of this was to encourage the manufacture of patented apparatus in foreign countries, and to stimulate their exportation to Great Britain in competition with British producers. With regard to the electro-chemical industry the progress which has been achieved by other nations, notably Germany, is very marvellous by comparison with the advance made by England, but to state the reasons why this industry has had such extraordinary development in Germany, notwithstanding that many of the fundamental inventions were made in England, would require a statement of the marked differences in the methods by which industrial progress is promoted in the two countries.

There has been very little solidarity among those interested in the commercial development of electricity, and except for the discussion of scientific subjects there has been very little organization with the object of protecting and promoting common interests.

**ELECTRIC WAVES.** § 1. Clerk Maxwell proved that on his theory electro-magnetic disturbances are propagated as a wave motion through the dielectric, while Lord Kelvin in 1853 (Phil. Mag. [4] 5: p. 393) proved from electro-magnetic theory that the discharge of a condenser is oscillatory, a result which Pedersen (Pogg. Ann. 103: p. 65; &c.) verified by a beautiful series of experiments. The oscillating discharge of a condenser had been inferred by Henry as long ago as 1824 from his experiments on the magnetization produced in needles by the discharge of a condenser. From these two results it follows that electric waves must be passing through the dielectric surrounding a discharge in the act of discharging, but it was not until 1887 that the existence of such waves was demonstrated by direct experiment. This great step was made by Hertz (Wied. Ann. 34: pp. 155, 551, 609; *Ausbreitung der elektrischen Kraft*, Leipzig, 1889), whose experiments on this subject form one of the greatest contributions ever made to experimental physics. The difficulty which had stood in the way of the observations of these waves was the absence of any method of detecting electrical and magnetic forces, excepted some millions of times per second, and only lasting for an exceedingly short time. This was removed by Hertz, who showed that such forces would produce small sparks between pieces of metal very nearly in contact, and that these sparks were sufficiently regular to be used to detect electric waves and to investigate their properties. Other and more delicate methods have subsequently been discovered, but the results obtained by Hertz with his detector were of such signal importance, that we shall begin our account of experiments on these waves by a description of some of Hertz's more fundamental experiments.

To produce the waves Hertz used two forms of vibrator. The first is represented in fig. 1. A and B are two zinc plates about 40 cm. square; to these brass rods, C, D, each about 30 cm. long, are soldered, terminating in brass balls E and F. To get good results it is necessary that these balls should be very brightly polished, and as they get roughened by the sparks which pass between them it is necessary to repolish them at short intervals; they should be shaded from light and from sparks, or other source of ultra-violet light. In order to excite the waves, C and D are connected to the two poles of an induction coil; sparks cross the air-gap which becomes a conductor, and the charges on the plates oscillate backwards and forwards like the charges on the coatings of a Leyden jar when it is short-circuited. The object of polishing the balls and screening off light is to get a sudden and sharp discharge, if the balls are rough there will be sharp points from which the charge will gradually leak, and the discharge will not be abrupt enough to start electric vibrations, as these have an exceedingly short period. From the open form of this vibrator we should expect the radiation to be very large and the rate of decay of the amplitude very rapid. Bjerknæs (Wied. Ann. 44: p. 74) found that the amplitude fell to 1/6 of the original value, after a time 47 where T was the period of the electrical vibrations. Thus after a few vibrations the amplitude becomes too inappreciable. To detect the waves produced by this vibrator Hertz used a piece of copper wire bent into a circle, the ends being furnished with two balls, or a ball and a point connected by a screw, so that the distance between them admitted of very fine adjustment. The radius of the circle for use with the vibrator just described was 35 cm., and was so chosen that the free period of the detector might be the same as that of the vibrator, and the effects in it increased by resonance. It is evident, however, that with a primary system so greatly damped as the vibrator used by Hertz, we could not expect very marked resonance effects, and as a matter of fact the accurate timing of vibrator and detector in this case is not very important. With electrical vibrators which can maintain a large number of vibrations, resonance effects are very striking, as is beautifully shown by the following experiment due to Lodge (Nature, 41: p. 306), whose researches have greatly advanced our knowledge of electric waves. A and C (fig. 2) are two Leyden jars, whose inner and outer coatings are connected by wires, B and D, bent so as to include a considerable area. There is a sir-break in the circuit connecting the inside and outside of one of the jars, A, and electrical oscillations are started in A by joining the inside and outside with the terminals of a coil or electrical engine. The circuit in the jar C is provided

![Fig. 1](image1)

![Fig. 2](image2)
with a sliding piece, F, by means of which the self-induction of the discharging circuit, and, therefore, the time of an electrical oscillation of the jar, can be adjusted. The inside and outside of this jar are put almost, but not quite, into electrical contact by means of a piece of tin-foil, E, bent over the lip of the jar. The jars are placed face to face so that the circuits B and D are parallel to each other, and approximately at right angles to the line joining their centres. When the electrical machine is in action sparks pass across the air-break in the circuit in A, and by moving the slider F it is possible to find one position for it in which sparks pass from the inside to the outside of C across the tin-foil, while when the slider is moved a short distance on either side of this position the sparks cease.

Hertz found that when he held his detector in the neighbourhood of the vibrator minute sparks passed between the balls. These sparks were not stopped when a large plate of non-conducting substance, such as the wall of a room, was interposed between the vibrator and detector, but a large plate of very thin metal stopped them completely.

To illustrate the analogy between electric waves and waves of light Hertz found another form of apparatus more convenient. The vibrator consisted of two equal brass cylinders, 12 cm. long and 3 cm. in diameter, placed with their axes coincident, and in the focal line of a large zinc parabolic mirror about 2 m. high, with a focal length of 125 cm. The ends of the cylinders nearest each other, between which the sparks passed, were carefully polished. The detector, which was placed in the focal line of an equal parabolic mirror, consisted of two lengths of wire,

![Fig. 3](image)

each having a straight piece about 50 cm. long and a curved piece about 15 cm. long bent round at right angles so as to pass through the back of the mirror. The ends which came through the mirror were connected with a spark micrometer, the sparks being observed from behind the mirror. The mirrors are shown in Fig. 3.

§ 2. Reflection and Refraction.—To show the reflection of the waves Hertz placed the mirrors side by side, so that their openings looked in the same direction, and their axes converged at a point about 3 m. from the mirrors. No sparks were then observed in the detector when the vibrator was in action. When, however, a large zinc plate about 2 m. square was placed at right angles to the line bisecting the angle between the axes of the mirrors sparks became visible, but disappeared again when the metal plate was twisted through an angle of about 15° to either side. This experiment showed that electric waves are reflected, and that, approximately at any rate, the angle of incidence is equal to the angle of reflection. To show refraction Hertz used a large prism made of hard pitch, about 1.5 m. high, with a slant side of 1.2 m. and an angle of 30°. When the waves from the vibrator passed through this the sparks in the detector were not excited when the axes of the two mirrors were parallel, but appeared when the axis of the mirror containing the detector made a certain angle with the axis of that containing the vibrator. When the system was adjusted for minimum deviation the sparks were most vigorous when the angle between the axes of the mirrors was 22°. This corresponds to an index of refraction of 1.69.

§ 3. Anomaly of a Plate of Tourmaline.—If a screen be made by winding wire round a large rectangular framework, so that the turns of the wire are parallel to one pair of sides of the frame, and if this screen be interposed between the parabolic mirrors when placed so as to face each other, there will be no sparks in the detector when the turns of the wire are parallel to the focal lines of the mirror; but if the frame is turned through a right angle so that the wires are perpendicular to the focal lines of the frame the sparks will be made. If a framework is substituted for the metal plate in the experiment on the reflection of electric waves, sparks will appear in the detector when the wires are parallel to the focal lines of the mirrors, and will disappear when the wires are at right angles to these lines. Thus the framework reflects but does not transmit the waves when the electric force in them is parallel to the wires, while it transmits but does not reflect waves in which the electric force is at right angles to the wires. The wire framework behaves towards the electric waves exactly as a plate of tourmaline does to waves of light. Du Bois and Kubena (Wied. Ann. 49, p. 591), by using a framework wound with very fine wire placed very close together, have succeeded in polarizing waves of radiant heat, whose wave length, although longer than that of ordinary light, is very small compared with that of electric waves.

§ 4. Angle of Polarization.—When light polarized at right angles to the plane of incidence falls on a refracting substance at an angle tan -μ, where μ is the refractive index of the substance, all the light is refracted and none reflected; whereas when light is polarized in the plane of incidence, some of the light is always reflected whatever the angle of incidence. Trouton (Nature, 39, p. 391) showed that similar effects take place with electric waves. From a paraffin wall 3 ft. thick, reflection always took place when the electric force in the incident wave was at right angles to the plane of incidence, whereas at a certain angle of incidence there was no reflection when the vibrator was turned, so that the electric force was in the plane of incidence. This shows that on the electromagnetic theory of light the electric force is at right angles to the plane of polarization.

§ 5. Stationary Electrical Vibrations.—Hertz (Wied. Ann. 34, p. 609) made his experiments on these in a large room about 15 m. long. The vibrator, which was of the type first described, was placed at one end of the room, its plates being parallel to the wall, at the other end a piece of sheet zinc about 4 m. by 2 m. was placed vertically against the wall. The detector—the circular ring previously described—was held so that its plane was parallel to the metal plates of the vibrator, its centre on the line at right angles to the metal plate bisecting at right angles the spark gap of the vibrator, and with the spark gap of the detector parallel to that of the vibrator. The following effects were observed when the distance was increased about . . . When it was close up to the zinc plate there were no sparks, but they began to pass feebly as soon as it was moved forward a little way from the plate, and increased rapidly in brightness until it was about 1.8 m. from the plate, when they attained their maximum. When its distance was still further increased they diminished in brightness, and vanished again at a distance of about 4 m. from the plate. When the distance was still further increased they reappeared, attained another maximum, and so on. They thus exhibited a remarkable periodicity similar to that which occurs when stationary vibrations are produced by the interference of direct waves with those reflected from a surface placed at right angles to the direction of propagation. Similar periodic alterations in the spark were produced by Hertz when the waves, instead of passing freely through the air and being reflected by a metal plate at the end of the room, were led along wires, as in the arrangement shown in fig. 4. L and K are metal plates placed parallel to the plates of the vibrator, long parallel wires being attached to act as guides to the waves which were reflected from the isolated end. (Hertz used only one
plate and one wire, but the double set of plates and wires introduced by Sarasin and De la Rive makes the results more definite.) In this case the detector is best placed so that its plane is at right angles to the wires, while the air space is parallel to the plane containing the wires. The sparks instead of vanishing when the detector is at the far end of the wire are a maximum in this position, but wax and wane periodically as the detector is moved along the wires. The most obvious interpretation of these experiments was the one given by Hertz—that there was interference between the direct waves given out by the vibrator and those reflected either from the plate or from the ends of the wire, this interference giving rise to stationary waves. The places where the electric force was a maximum were the places where the sparks were brightest, and the places where the electric force was zero were the places where the sparks vanished. On this explanation the distance between two consecutive places where the sparks vanished would be half the wave length of the waves given out by the vibrator.

Some very interesting experiments made by Sarasin and De la Rive (Comptes rendus, 113, p. 486) showed that this explanation of the phenomenon is wrong. They found that at large distances from the source, the direct waves were very feeble, and that the detection was chiefly due to the reflected waves. They found that the distance between the two consecutive places where the sparks vanished depended mainly upon the size of the detector, and very little upon that of the vibrator. With very small detectors they found the distance small, with large detectors, large; in fact it is directly proportional to the diameter of the detector. We can see that this result is a consequence of the large damping of the oscillations of the vibrator and the very small damping of those of the detector. Bjerknæ showed that the time taken for the amplitude of the vibrations of the vibrator to sink to $e$ of their original value was only $4T'$, while for the detector it was $500T'$, with $T$ and $T'$ respectively the times of vibration of the vibrator and the detector. The rapid decay of the oscillations of the vibrator will still the interference between the direct and the reflected wave, as the amplitude of the direct wave will, since it is emitted later, be much smaller than that of the reflected one, and not able to annul its effects completely; while the well-maintained vibrations of the detector will interfere and produce the effects observed by Sarasin and De la Rive. To see this let us consider the extreme case in which the oscillations of the vibrator are absolutely dead-beat. Here an impulse, starting from the vibrator on its way to the reector, strikes against the detector and sets it in vibration; it then travels up to the plate and is reflected, the electric force in the impulse being reversed by reflection. After reflection the impulse again strikes the detector, the intensity of which is subject to the effects of the first impact; if the phase of this vibration is such that the reflected impulse tends to produce a current round the detector in the same direction as that which is circulating from the effects of the first impact, the sparks will be increased, but if the reflected impulse produces a current in the opposite direction the sparks will be diminished. Since the electric force is reversed by reflection, the greatest increase in the sparks will take place when the impulse finds, on its return, the detector in the opposite phase to that in which it left it; that is, if the time which has elapsed between the departure and return of the impulse is equal to an odd multiple of half the time of vibration of the detector. If $d$ is the distance of the detector from the reector when the sparks are brightest, and $V$ the velocity of propagation of electromagnetic disturbance, then $2d/V = (2n + 1)(T'/2)$; where $n$ is an integer and $T'$ the time of vibration of the detector, the distance between two spark maxima will be $VTP'$, and the places where the sparks are a minimum will be midway between the maxima. Sarasin and De la Rive found that when the same detector was used the distance between two spark maxima was the same with the waves through air reflected from a metal plate and with those guided by wires and reflected from the free ends of the wires, the inference being that the velocity of waves along wires is the same as that through the air. This result, which follows from Maxwell's theory, when the wires are not too fine, had been questioned by Hertz on account of some of his experiments on wires.

§ 6. Detectors.—The use of a detector with a period of vibration of its own thus tends to make the experiments more complicated, and many other forms of detector have been employed by subsequent experimenters. For example, in place of the sparks in air the luminous discharge through a rarefied gas has been used by Dragounis, Lecher (who used tubes without electrodes laid across the windows in an arrangement resembling that shown in fig. 7) and Arons. A tube containing neon at a low pressure is especially suitable for this purpose. Zehnder (Wied. Ann. 47, p. 777) used an exhausted tube to which an external electromotive force almost but not quite sufficient of itself to produce a discharge was applied; here the additional electromotive force due to the waves was sufficient to start the discharge. Detectors depending on the heat produced by the rapidly alternating currents have been used by Paaßow and Rubens, Rubens and Ritter, and I. Klemenčič. Rubens measured the heat produced by a bolometer arrangement, and Klemenčič used a thermo-electric method for the same purpose; in consequence of the great increase in the sensitiveness of galvanometers with the increase of current, these methods are now very frequently resorted to. Boltzsche used an electroscope as a detector. The spark gap consisted of a ball and a point, the ball being connected with the electroscope and the point with the battery of 200 dry cells. When the spark passed the cells charged up the electroscope. Ritter utilized the contraction of a frog's leg as a detector, Lucas and Garrett the explosion produced by the sparks in an explosive mixture of hydrogen and oxygen; while Bjerknæ and Franke used the mechanical attraction between oppositely charged conductors. If the two sides of the spark gap are connected with the two pairs of quadrants of a very delicate electrometer, the needle of which is connected with one pair of quadrants, there will be a deflection of the electrometer when the detector is struck by electric waves. A very efficient detector is that invented by E. Rutherford (Trans. Roy. Soc. A. 1897, 189, p. 1); it consists of a bundle of fine iron wires magnetized to saturation and placed inside a small magnetizing coil, through which the electric waves cause rapidly alternating currents to pass which demagnetize the soft iron. If the instrument is used to detect waves in air, long straight wires are attached to the ends of the demagnetizing coil to collect the energy from the field; to investigate waves in wires it is sufficient to make a loop or two in the wire and place the magnetized piece of iron inside it. The amount of magnetization which can be observed by the change in the deflection of a magnetometer placed near the iron, and the currents which can be accurately determined can be made with ease with this apparatus. It is also very delicate, though in this respect it does not equal the detector to be next described, the coherer; Rutherford got indications in 1895 when the vibrator was $\frac{1}{2}$ of a mile away from the detector, and where the waves had to traverse a thickly populated part of Cambridge. It can also be used to measure the coefficient of damping of the electric waves, for since the wire is initially magnetized to saturation, if the direction of the current when it first begins to flow in the magnetizing coil is such as to tend to increase the magnetisation of the wire, the magnetic field will produce no effect, and it will not be until the current is reversed that the wire will lose some of its magnetization. The effect then gives the measure of the intensity half a period after the commencement of the waves. If the wire is put in the coil the opposite way, i.e. so that the magnetic force due to the current begins at once to demagnetize the wire, the demagnetization gives a measure of the initial intensity of the wave. Comparing this result with that obtained when the waves were reversed, we get the coefficient of damping. A very convenient detector of electric waves is the one discovered almost simultaneously by Fessenden (Electrotech. Zeits., 1903, 24, p. 586) and Schömlich (ibid. p. 959). This consists of an electrolytic cell in which one of the electrodes is an exceedingly fine point. The electromotive force in the circuit is small, and there is large polarization in the circuit with only a small current. When the
circuit is struck by electric waves there is an increase in the currents due to the depolarization of the circuit. If a galvanometer is in the circuit, the increased deflection of the instrument will indicate the presence of the wave. Through the action of the spark, there is also a partial destruction of the atmosphere of the spark gap. The ordinary vibrating break of the coil is not used, a single spark made by making and breaking the circuit by means of a button outside the box being employed in its place. The spiral spring is as previously described; it is shielded from external disturbance by being enclosed in a metal box provided with a funnel-shaped opening to admit the radiation. The wires leading from the coherer to the galvanometer are also surrounded by metal tubes to protect them from stray radiation. The radiating apparatus and the receiver are mounted on stands sliding in an optical bench. A parallel beam of radiation is required, a cylinder of glass or a lens of flint glass is mounted in a tube fitting on to the radiating tube and stopped by a guide when the spark is at the focal point of the lens. For experiments requiring angular focus, the radiation is modified by using a mirror placed on the axis of the tube, the receiver being carried on a radial arm and pointing to the centre of the circle. The arrangement is represented in Fig. 5.

With this apparatus the laws of reflection, refraction and polarization can readily be verified, and also the double refraction of crystals and of bodies possessing a fibrous or laminated structure such as jute or books. The double refraction of electric waves seems first to have been observed by Righi, and other researches on this subject have been made by Garbasso and Mack. Bosc showed the rotation of the plane of polarization by means of pieces of twisted jute rope; if the waves were arranged in such a way that their twists were all in one direction and placed in the path of the radiation, they rotated the plane of polarization in a direction depending upon the direction of twist; if they were mixed so that there were as many twisted in one direction as the other, there was no rotation.

A series of experiments showing the complete analogy between electric and light waves is described by Righi in his book L'Optica delle osillazioni elettriche. Righi's exciter, which is especially convenient when large statical electric machines are used instead of induction coils, is shown in Fig. 6. E and F are balls connected with the terminals of the machine, and AB and CD are conductors insulated from each other, the ends B, C, between which the spark passes, being immersed in vaseline oil. The period of the vibrations given out by the system is adjusted by means of terminal plate M and pulleys 

methods the terminals between which the arc is passing are connected through coils with self-induction, to the plates of a condenser of reversed polarity. The arc is not burnt out, but is continually produced and renewed. The waves are excited by sparking between two platinum electrodes placed 1 cm apart and the distance between the electrodes can be adjusted by bending the electrodes. The diameter of the sphere is 8 mm., and the wave length of the shortest electrical wave generated is said to be about 0.6 mm. The beads are connected with the terminals of a small induction coil, which, with the battery to work it and the sparking arrangement, are enclosed in a metal box. The radiation passing through a metal wire, exposed to the spark, is shielded from external disturbance by being enclosed in a metal box provided with a funnel-shaped opening to admit the radiation. The wires leading from the coherer to the galvanometer are also surrounded by metal tubes to protect them from stray radiation. The radiating apparatus and the receiver are mounted on stands sliding in an optical bench. A parallel beam of radiation is required, a cylinder of glass or a lens of flint glass is mounted in a tube fitting on to the radiating tube and stopped by a guide when the spark is at the principal focal line of the lens. For experiments requiring angular focus, the radiation is modified by using a mirror placed on the axis of the tube, the receiver being carried on a radial arm and pointing to the centre of the circle. The arrangement is represented in Fig. 5.
and capacity are large so that the frequency comes within the limits of the frequency of audible notes, the system gives out a musical note. and the arrangement is often referred to as the singing arc, and Rubens a bolometer, but Rutherford's detector is the most convenient and accurate. If this detector is placed in a fixed position at the end of the circuit, it is found that the deflections of this detector depend greatly upon the position of the bridge LM, rising rapidly to a maximum for some positions, and falling rapidly away when the bridge is displaced. As the bridge is moved from the coil end towards the detector, the deflections show periodic variations, such as are represented in fig. 8 when the ordinates represent the deflections of the detector and the abscissae the distance of the bridge from the ends D and E. The maximum deflections of the detector correspond to the positions in which the two circuits DFLMGE, HLMJ (in which the vibrations are but slightly damped) are in resonance. For since the self-induction and resistance of the bridge LM is very much in comparison with that of the circuit beyond, it follows from the theory of circuits in parallel that only a small part of the current will in general flow round the longer circuit; it is only when the two circuits DFLMGE, HLMJ are in parallel that the current will flow round the latter. Hence when we get a maximum effect in the detector we know that the waves we are dealing with are those corresponding to the free periods of the system HLMJ, so that if we know the free periods of this circuit we know the wave length of the electric waves under consideration. Thus if the ends of the wires H, J are free and have no capacity, the current along them must vanish at H and J, which must be the case in all electric condensers. Hence half the wave length must be an odd submultiple of the length of the circuit HLMJ. If H and J are connected together the wave length must be a submultiple of the length of this circuit. When the capacity at the ends is appreciable the wave length of the circuit is further circuit were hardly appreciably diminished when the main wires were cut between PL and QM. Blondlot used a modification of this apparatus better suited for the production of short waves. In his form (fig. 9) the exciter consists of two semicircular arms connected with the terminals of an induction coil, and the long wires, instead of being connected with the small plates, form a circuit round the exciter.

As an example of the use of Lecher's arrangement, we may quote Drude's application of the method to find the specific inductive capacity of dielectrics under electric oscillations of varying frequency. In this application the ends of the wire are connected to the plates of a condenser, the space between whose plates can be filled with a liquid whose specific inductive capacity is required, and the bridge is moved until the detector at the end of the circuit gives the maximum deflection. Then

\[ \frac{\cot 2 \lambda}{\lambda} = \frac{C}{2 \lambda} \]

where \( i \) is the distance of the detector from the bridge and \( C \) is the capacity of unit length of the wire. In the condenser part of the lines of force will pass through air and part through the dielectric; hence \( C \) will be of the form \( C + iK \), where \( K \) is the specific inductive capacity of the dielectric. Hence if \( i \) is the distance of maximum deflection when the dielectric is replaced by air, \( i' \) when filled with a dielectric whose specific inductive capacity is known to be \( K' \), and \( i'' \) the distance when filled with the dielectric whose specific inductive capacity is required, we easily see that

\[ \frac{\cot 2 \lambda}{\lambda} = \frac{\cot 2 \lambda}{\lambda} - \frac{1 - K}{1 - K'} \]

an equation by means of which \( K \) can be determined. It was in this way that Drude investigated the specific inductive capacity with varying frequency, and found a falling off in the specific inductive capacity with increase of frequency when the dielectrics contained the radicle OH. In another method used by him, the wires were led through long tanks filled with the liquid whose specific inductive capacity was required; the velocity of propagation of the electric waves along the wires in the tank being the same as the velocity of propagation of an electromagnetic disturbance through the liquid filling the tank, if we find the wave length of the waves along the wires in the tank, due to a vibration of a given frequency, and compare this with the wave lengths corresponding to the same frequency when the wires are surrounded by air, we obtain the velocity of propagation of electromagnetic disturbance through the fluid, and hence the specific inductive capacity of the fluid.

§ 10. Velocity of Propagation of Electromagnetic Effects through Air.

The experiments of Sarasin and de la Rive already described (see § 8) have shown that, as theory requires, the velocity of propagation of electric effects through air is the same as along wires. The same result had been arrived at by J. J. Thomson, although from the method he used greater differences between the velocities might have escaped detection than was possible by Sarasin and de la Rive's method. The velocity of waves along wires has been directly determined by Blondlot by two different methods. In the first the detector consisted of two parallel plates about 6 cm. in diameter placed a fraction of a millimetre apart, and forming a condenser whose capacity \( C \) was determined in electromagnetic measure by Maxwell's method. The plates were connected by a rectangular circuit whose self-induction \( L \) was calculated from the dimensions of the rectangle and the size of the wire. The time of vibration \( T \) is equal to \( 2\pi \sqrt{LC} \). (The wave length corresponding to this time is long compared with the length of the circuit, so that the use of this formula is legitimate.) This detector is placed between two parallel wires, and the waves produced by the exciter applied in front of a moved bridge. When this bridge is placed beyond the detector vigorous sparks are observed, but as the bridge is pushed away a place is reached where the sparks disappear; this place is distance \( 2\lambda \) from the detector, when \( \lambda \) is the wave length of the vibration given out by the detector. The sparks again disappear when the distance of the bridge from the detector is \( 3\lambda / 4 \). Thus by measuring the distance between two consecutive positions of the bridge at which the sparks disappear \( \lambda \) can be determined.
and $v$, the velocity of propagation, is equal to $\lambda/t$. As the means of a number of experiments found $v$ to be $3\times10^8$ cm./sec., which, within the errors of experiment, is equal to $3\times10^8$ cm./sec., the velocity of light. A second method used by Blondlot, and one which does not involve the calculation of the period, is as follows:—A and A’ (fig. 10) are two equal lengths of wire, the outer and inner coatings are connected with the poles of the induction coil by means of metal pieces $b$ and $b’$. The sharply pointed conductors $p$ and $p’$, the points of which have to $0.1$ mm. apart, are connected with the rings of the induction coil by means of copper wires. When a spark passes between $b$ and $b’$, a spark also passes between $p$ and $p’$, and this is followed by another spark when the waves travelling through the lengths $a_a$, $a_b$, $a_a’$, $a_b’$ reach $p$ and $p’$. The time between the passage of these sparks, called $t$, is the time taken by the waves to travel 1092 cm., was observed by means of a rotating mirror, and the velocity measured in 15 experiments was found to be $3\times10^8$ cm./sec., thus agreeing well with that deduced by the preceding method. Other determinations of the velocity of electromagnetic propagation have been made by Lodge and Glazebrook, and by Saunders.

On Maxwell’s electromagnetic theory the velocity of propagation of electromagnetic disturbances should equal the velocity of light; and also the ratio of the electromagnetic unit of electricity to the electrostatic unit. A large number of determinations of this ratio have been made:

The mean of these determinations is $3.0019\times10^8$ cm./sec., while the mean of the last five determinations of the velocity of light in air is given by Himstedt as $3.0020\times10^8$ cm./sec. From these experiments we conclude that the velocity of propagation of an electromagnetic disturbance is equal to the velocity of light, and to the velocity required by Maxwell’s theory.

In experimenting with electromagnetic waves it is in general more difficult to measure the period of the oscillations than their wave length. Rutherford used a method by which the period of the vibration can easily be determined. It is based upon the visual observation of the distribution of alternating currents in two circuits, ADB in parallel. If A and B are respectively the maximum currents in the circuits ADB, ABD, then

$$A = \frac{S^2(N-M)^2}{R^2 + (L-M)^2},$$

$$B = \frac{S^2}{R^2 + (L-M)^2}.$$ 

when $R$ and $S$ are the resistances, $L$ and $N$ the coefficients of self-induction of the circuits ADB, ABD respectively, $M$ the mutual induction between the circuits, and $p$ the frequency of the currents. Rutherford detected were placed in the two circuits, and the circuits adjusted until they showed that $A = B$; when this is the case

$$p^2 = \frac{N-L}{2M(N-L)}.$$

If we make one of the circuits, ADB, consist of a short length of a high liquid resistance, so that $S$ is large and $N$ small, and the other circuit ADB of a low metallic resistance bent to have an additional self-induction, the preceding equation becomes

$$p^2 = \frac{S}{L},$$

so that when $S$ and $L$ are known $p$ can be readily determined.

**Electrochemistry.** The present article deals with processes that involve the electrolysis of aqueous solutions, whilst those in which electricity is used in the manufacture of chemical products at furnace temperatures are treated under ElectroMetallurgy, although, strictly speaking, in some cases (e.g. calcium carbide and phosphorus manufacture) they are not truly metallurgical in character. For the theory and elemental laws of electro-deposition see ELECTROLYSIS, and for the construction and use of electrical generators see Dynamo and Battery: Electric. The importance of the subject may be gauged by the fact that all the aluminium, magnesium, sodium, potassium, calcium carbide, carbonium and artificial graphite, now placed on the market, is made by electrical processes, and that the use of such processes for the refining of copper and silver, and in the manufacture of phosphorus, potassium chlorate and bleach, already pressing very heavily on the older non-electrical systems, is every year extending. The convenience also with which the energy of waterfalls can be converted into electric energy has led to the introduction of chemical industries into countries and districts where, owing to the absence of coal, they were previously unknown. Norway and Switzerland have become important producers of chemicals, and pastoral districts such as those in which Niagara or Foyers are situated manufacturing centres. In the work the development of the electrochemical industry is in a marked degree altering the distribution of trade throughout the world.

**Electrolytic Refining of Metals.**—The principle usually followed in the electrolytic refining of metals is to cast the impure metal into plates, which are exposed as anodes in a suitable solvent, commonly a salt of the metal under treatment. On passing a current of electricity, of which the volume and pressure are adjusted to the conditions of the electrolyte and electrodes, the anode slowly dissolves, leaving the insoluble impurities in the form of a sponge, if the proportion be considerable, but otherwise as a mud or slime which becomes detached from the anode surface and must be prevented from coming into contact with the cathode. The metal to be refined passing into solution is concurrently deposited at the cathode. Soluble impurities which are more electro-negative than the metal under treatment must, if present, be removed by a preliminary process, and the voltage and other conditions must be so selected that these as well as the more electro-positive metals are co-deposited with the metal to be refined. From these and other considerations it is obvious that (1) the electrolyte must be such as will freely dissolve the metal to be refined; (2) the electrolyte must be able to dissolve the major portion of the anode, otherwise the mass of insoluble matter on the outer layer will prevent access of electrolyte to the core, which will thus escape refining; (3) the electrolyte should, if possible, be incapable of dissolving metals more electro-negative than that to be refined; (4) the proportion of soluble electro-positive impurities must not be excessive, or these substances will accumulate too rapidly in the solution and necessitate its frequent purification; (5) the current density must be so adjusted to the strength of the solution and to other conditions that no relatively electro-positive metal is deposited, and that the cathode deposit is physically suitable for subsequent treatment; (6) the current density should be as high as is consistent with the production of a pure and sound deposit, without undue expense of voltage, so that the operation may be rapid and the "turnover" large; (7) the electrolyte should be as good a conductor of electricity as possible, and should not, ordinarily, be altered chemically by exposure to air; and (8) the use of porous partitions should be avoided, as they increase the resistance and usually require frequent renewal. For details of the practical methods see Gold; Silver; Copper and lead and other metals.

**Electrolytic Manufacture of Chemical Products.**—When an aqueous solution of the salt of an alkali metal is electrolysed, the
metal reacts with the water, as is well known, forming caustic alkali, which dissolves in the solution, and hydrogen, which comes off spontaneously. The alkali, when water is taken evaporated for the production of caustic alkali without the use of a separate current, byimmersing iron and copper plates on opposite sides of a porous (biscuit-ware) partition in a suitable cell, containing a solution of the salt to be electrolysed, at 21°-5° C. (70°-59° F.). The solution of the iron anode was intended to afford the necessary energy. In the same year another patent was granted to C. Watt for a similar process, involving the employment of an extended generated current. When an alkaline solution of sodium chloride, is electrolysed with one electrode immersed in a porous cell, while caustic soda is formed at the cathode, chlorine is deposited at the anode. If the latter be insoluble, the gas diffuses into the solution and, when this becomes saturated, escapes into the air. If, however, no porous division be used to prevent the intermingling by diffusion of the anode and cathode solutions, a complicated set of subsidiary reactions takes place. The chlorine reacts with the caustic soda, forming sodium hypochlorite, and this, in turn, with an excess of chlorine and at higher temperatures, becomes for the most part converted into chlorate, whilst any simultaneous electrolysis of a hydroxide or water and a chloride (so that hydroxyl and chlorine are simultaneously liberated at the anode) also produces oxygen-chlorine compounds direct. At the same time, the diffusion of these compounds into contact with the cathode leads to a partial reduction of the chlorine. If the removal of combined oxygen by the interposed cell is not effective, the process is not entirely reversed. In the case where the original chloride is thus reproduced, the efficiency of the process is of course diminished. It is obvious that, with suitable methods and apparatus, the electrolysis of alkaline chlorides may be made to yield chlorine, hypochlorites (bleaching liquors), chlorates or caustic alkali, but that great care must be exercised if any of these products is to be obtained pure and with economy. Many patents have been taken out in this branch of electrochemistry, but the one which has been most successful is that of E. Reven (Journ. Soc. Chem. Industr., 1887, vol. vi. p. 170, and 1888, vol. vii. p. 292), and to later papers by P. Schoop (Zeitschrift, Elektrochem., 1891, vol. vii. pp. 688, 87, 207, 209, 236).

E. Keller, who in 1886 patented the use of cathode (caustic soda) and anode (chlorine) liquors in the manufacture of cellulose from wood-fibre, and has since evolved many similar processes, has produced an apparatus that has been largely used. It consists of a stone-wear tank with a thin sheet of platinum-iridium alloy at either end forming the primary electrodes, and between them a number of glass plates reaching nearly to the bottom, each having a platinum-gauze sheet on either side; the two sheets belonging to each plate are in metallic connexion, but insulated from all the others, and form intermediately or bi-polar electrodes. A 10-12% solution of sodium chloride is introduced to the apparatus and to overflow through troughs, by which it is conveyed (if necessary through a cooling apparatus) back to the circulating tank. Such a plant has been set up in which a plant has been set up at which the liquor containing 1% of available chlorine per kilowatt hour, or 0-177 gallon per c.h.p. hour. Keller has also patented a "bleaching-block," as he terms it, consisting of a frame carrying parallel plates similar to those last described. The block is immersed in the solution to be bleached, and may be lifted in or out as required. O. Knöfler and Gebauer have also a system of bi-polar electrodes, mounted in a frame in appearance resembling a filter-press.

Other Electrochemical Processes.—It is obvious that electrolytic iodine and bromine, and oxygen compounds of these elements, may be produced by methods similar to those applied to chlorides (see above), and Wagner and Co. (Journ. Soc. Chem. Industr., 1891, vol. vii. p. 207) and others have patented processes with this end in view. Hydrogen and oxygen may also be produced electrolytically as gases, and their respective reducing and oxidizing powers at the moment of deposition on the electrode are frequently used in the laboratory, and to some extent industrially, chiefly in the field of organic chemistry. Similarly, the formation of organic halogen products may be effected by electrolytic chlorine, as, for example, the manufacture, in the propionic acids, of propionaldehyde by the electrolysis of propionic acid thereon in an anode cell in which the electrolyte is a strong solution of potassium chloride. Again, anode reactions, such as are observed in the electrolysis of the fatty acids, may be utilized, as, for example, when the radical CH₃COOH—deposited at the anode in the electrolysis of acetic acid—is dissociated, two of the groups react to give one molecule of ethane, CH₄, and two of carbon dioxide. This, which has long been recognized as a class-reaction, is obviously capable of endless variations. Many electrolytic methods have been proposed for the purification of sugar; in some of them soluble anodes are used for a few minutes in weak alkaline solutions, so that the caustic alkali from the cathode reaction may precipitate chemically the hydroxide of the anode metal dissolved in the liquid, the precipitate carrying with it mechanically some of the impurities present, and thus clarifying the solution. In others the current is applied for a longer time to the original sugar-solution with H₂CO₃ or sodium carbonate. E. P. Peters has found that with these methods the best results are obtained when ozone is employed in addition to electrolytic oxygen. Use has been made of electrolysis in tanning operations, the current being passed through the tan-liquors containing the hides. The current, by endosmosis, favours the passage of the solution into the hide-substance, and at the same time appears to assist the chemical combinations there occurring; hence a great reduction in the time required for the completion of the process. Many patents have been taken out in this direction, one of the best known being that of Groth, experimented upon by S. Riedel and A. P. Trotter (Journ. Soc. Chem. Industr., 1891, vol. x. p. 435).
who employed copper anodes, 4 sq. ft. in area, with current-densities of 0.375 to 1 (ranging in some cases to 2) amperes per sq. ft., the best results being obtained with the smaller current-densities. Electrochemical processes are often indirectly used, as for example in the Villon process (Elec. Rev., New York, 1889, vol. xxxv. p. 375) applied in Russia to the manufacture of alcohol, by a series of chemical reactions starting from the production of acetylene by the action of water upon calcium carbide. The production of ozone in small quantities during electrolysis, and by the so-called silent discharge, has long been known, and the Siemens induction tube has been developed for use industrially. The Siemens and Halke ozonizer, in form somewhat resembling the ordinary gas-oven, was invented in 1882 by W. T. Bramley (Elec. Rev., New York, 1892). Ozonization is extensively employed in Germany; working with an alternating current transformed up to 6500 volts, it has been found to give 280 grains or more of ozone per e. h. p. hour. (P. Andreoli (whose first British ozone patent was No. 174,426 of 1891) uses flat aluminium plates and points, and working with an alternating current of 5000 volts is said to have obtained 1440 grains per e. h. p. hour. Yarrold's process, using corrugated glass plates coated on one side with gold or other metal leaf, is stated to have yielded as much as 2700 grains per e. h. p. hour. The ozone so prepared has numerous uses, as, for example, in bleaching oils, waxes, fabrics, &c., sterilising drinking-water, maturing wines, cleaning foul beer-casks, oxidizing oil, and in the manufacture of vanillin.

For further information the following books, among others, may be consulted:—Haber, Grundriss der technischen Elektrochemie (Berlin, 1893 and 1895); Fritz and Martin, Electro Smelting and Refining (London, 1904); E. D. Peters, Principles of Copper Smelting (New York, 1897); F. Peters, Angewandte Elektrochemie, vols. ii. and iii (Leipzig, 1900); Gore, The Art of Electrolytic Separation of Metals (London, 1906); G. Langer, Vollstandiges Handbuch der galvanischen Metall-Niederschlage (Leipzig, 1903); Eng. trans. by W. T. Bramley (London, 1908); A. W. and W. A. Young, Electro Refining of Copper (London, 1902); W. H. Wahl, Practical Guide to the Cold and Silver Electroplater, &c. (Philadelphia, 1885); Wilson, Stereotyping and Electrotyping (London); Lange, Salpaucid Acid and Alkali (London, 1896). Also papers in various technical periodicals. The industrial aspect is treated in a Cartside Report, Some Electro-Chemical Centres (Manchester, 1908), by J. N. Pring. (W. G. M.)

ELECTROCUTION (an anomaloue derivative from "electro-execution"); syn. "electrothanasia"), the popular name, invented in America, for the infliction of the death penalty on criminals (see CAPITAL PUNISHMENT) by passing through the body of the condemned a sufficient current of electricity to cause death. The method was first adopted in the state of New York by a law making this method obligatory having been passed and approved by the governor on the 4th of June 1888. The law provides that there shall be present, in addition to the warden, two physicians, twelve reputable citizens of full age, seven deputy sheriffs, and such ministers, priests or clergymen, not exceeding two, as the criminal may request. A post-mortem examination of the body of the convict is required, and the body, unless claimed by relatives, is interred in the prison cemetery with a sufficient quantity of quicklime to consume it. The law became effective in New York on the 1st of January 1889. The first criminal to be executed by electricity was William Kemmler, on the 6th of August 1890, at Auburn prison. The validity of the New York law had previously been attacked in regard to this case (Re Kemmler, 1899; 136 U.S. 436), as providing a cruel and unusual punishment and therefore being contrary to the Constitution; but it was sustained in the state courts and finally in the Federal courts. By 1906 about one hundred and fifteen murderers had been successfully executed by electricity in New York state in Sing Sing, Auburn and Dannemora prisons. The method has also been adopted by the states of Ohio (1886), Massachusetts (1888), New Jersey (1906), Virginia (1906) and North Carolina (1910).

The apparatus consists of a stationary engine, an alternating dynamo capable of generating a current at a pressure of 2000 volts, a "death-chair" with adjustable head-rest, binding straps and adjustable electrodes devised by E. F. Davis, the state electrician of New York. The voltmeter, ammeter and

switch-board controlling the current are located in the execution-room; the dynamo-room is communicated with by electric signals. Before each execution the entire apparatus is thoroughly tested. When everything is in readiness the criminal is brought in and seated himself in the death-chair, both his head, chest, arms and legs are secured by broad straps; one electrode thoroughly moistened with salt-solution is affixed to the head, and another to the calf of one leg, both electrodes being moulded so as to secure good contact. The application of the current is usually as follows: the current is made with a high voltage (1700-1800 volts) for 5 to 7 seconds, reduced to 200 volts until a half-minute has elapsed; raised to high voltage for 3 to 5 seconds, again reduced to 200 volts for 5 to 10 seconds, again reduced to a low voltage until one minute has elapsed, when it is again raised to the high voltage for a few seconds and the contact broken. The ammeter usually shows that from 7 to 10 amperes pass through the criminal's body. A second or even a third brief contact is sometimes made, partly as a precautionary measure, but rather the more completely to abolish reflexes in the dead body. Calculations have shown that by this method of execution from 7 to 10 h. p. of energy are liberated in the criminal's body. The time consumed by the strapping-in process is usually about 45 seconds, and the first contact is made about 70 seconds after the criminal has entered the death-chamber.

When properly performed the effect is painless and instantaneous death. The mechanism of life, circulation and respiration cease with the first contact. Consciousness is blotted out instantly, and the prolonged application of the current ensures permanent derangement of the vital functions beyond recovery. Occasionally the drying of the sponges through the generation of heat causes desquamation or superficial blistering of the skin at the site of the electrodes. Post-mortem discoloration, or post-mortem lividity, often appears during the first contact. The pupils of the eyes dilate instantly and remain dilated after death.

The post-mortem examination of "electrocuted" criminals reveals a number of interesting phenomena. The temperature of the body rises promptly after death to a very high point. At the site of the leg electrode a temperature of over 128° F. was registered within fifteen minutes in many cases. After the removal of the brain the temperature recorded in the spinal canal was often over 120° F. The development of this high temperature is to be regarded as resulting from the active metabolism of tissues not (somatically) dead within a body where all vital mechanisms have been abolished there being no circulation to carry off the generated heat. The heart, at first flaccid when exposed soon after death, gradually contracts and assumes a tetanized condition; it empties itself of all blood and takes form of a heart in systole. The lungs are usually devoid of blood and weigh only 7 or 8 ounces (avoided). Each is profoundly altered biochemically; it is of a very dark colour and it rarely coagulates. (E. A. S.)

ELECTROKINETICS: that part of electrical science which is concerned with the properties of electric currents.

Classification of Electric Currents.—Electric currents are classified into (a) conduction currents, (b) convection currents, (c) displacement or dielectric currents. In the case of conduction currents electricity flows or moves through a stationary material body called the conductor. In convection currents electricity is carried from place to place with and on moving material bodies or particles. In dielectric currents there is no continued movement of electricity, but merely a limited displacement through or in the mass of an insulator or dielectric. The path in which an electric current exists is called an electric circuit, and may consist wholly of a conducting body, or partly of a conductor and insulator or dielectric, or wholly of a dielectric. In cases in which the three classes of currents are present together the true current is the sum of each separately. In the case of conduction currents the circuit consists of a conductor immersed in a non-conductor, and may take the form of a thin wire or cylinder, a sheet, surface or solid. Electric conduction currents may take place in space of one, two or three dimensions, but for
the most part the circuits we have to consider consist of thin cylindrical wires or tubes of conducting material surrounded with an insulator; hence the case which generally presents itself is that of electric flow in space of one dimension. Self-closed electric currents taking place in a sheet of conductor are called "eddy currents."

Although in ordinary language the current is said to flow in the conductor, yet according to modern views the real pathway of the energy transmitted is the surrounding dielectric, and the so-called conductor or wire merely guides the transmission of energy in a certain direction. The presence of an electric current is recognised by three qualities or powers: (1) by the production of a magnetic field, (a) in the case of conduction currents, by the production of heat in the conductor, and (b) if the conductor is an electrolyte and the current, unidirectional, by the occurrence of chemical decomposition in it. An electric current may also be regarded as the result of a movement of electricity across each section of the circuit, and is then measured by the quantity conveyed per unit of time. Hence if \( dq \) is the quantity of electricity which flows across any section of the conductor in the element of time \( dt \), the current \( i = dq/dt \).

Electric currents may also be classified as constant or variable and as unidirectional or "direct," that is flowing always in the same direction, or "alternating," that is reversing their direction at regular intervals. In the last case the variation of current may follow any particular law. It is called a "periodic current," if the curve of current values is repeated during a certain time called the periodic time, during which the current reaches a certain maximum value, first in one direction and then in the opposite, and in the intervals between has a zero value at certain instants. The frequency of the periodic current is the number of periods or cycles in one second, and alternating currents are described as low frequency or high frequency, in the latter case having some thousands of periods per second. A periodic current may be represented either by a wave diagram, or by a polar diagram. In the former case, we take a straight line to represent the uniform flow of time, and at small equal intervals set up perpendiculars above or below the time axis, representing to scale the current at that instant in one direction or the other; the extremities of these ordinates then define a wavy curve which is called the wave form of the current (fig. 1). It is obvious that this curve can only be a single valued curve. In one particular and important case the form of the current curve is a simple harmonic curve or simple sine curve. If \( T \) represents the periodic time in which the cycle of current values takes place, whilst \( n \) is the frequency or number of periods per second and \( p \) stands for \( 2\pi n \) and \( i \) is the value of the current at any instant \( t \), and \( i \) its maximum value, then in this case we have \( i = I \sin \alpha \).

Such a current is called a "sine current" or simple periodic current.

In a polar diagram (fig. 2) a number of radial lines are drawn from a point at small equiangular intervals, and on these lines are set off lengths proportional to the current value of a periodic current at corresponding intervals during one complete period represented by four right angles. The extremities of these radial delineate a polar curve. The polar form of a simple sine current is obviously a circle drawn through the origin. As a consequence of Fourier's theorem it follows that any periodic curve having any wave form can be imitated by the superposition of simple sine currents differing in maximum value and in phase.

One of the main objects of electrokinetic investigations is to make it possible to measure electric currents, either by the magnetic effect it produces at some point outside its circuit, or by the amount of electrochemical decomposition it can perform in a given time on a selected standard electrolyte. Limiting our consideration to the case of linear currents or currents flowing in thin cylindrical wires, a definition may be given in the first place of the unit electric current in the centimetre, gramme, second (C.G.S.) of electromagnetic measurement (see UNITS, PHYSICAL). H. C. Oersted discovered in 1820 that a straight wire conveying an electric current is surrounded by a magnetic field the lines of which are self-closed lines embracing the electric circuit (see ELECTRICITY and ELECTROMAGNETISM). The unit current in the electromagnetic system of measurement is defined as the current which, flowing in a thin wire bent into the form of a circle of one centimetre in radius, creates a magnetic field having a strength of \( 1 \pi \) units at the centre of the circle, and therefore would exert a mechanical force of \( 1 \pi \) dynes on a unit magnetic pole placed at that point (see MAGNETISM). Since the length of the circumference of the circle of unit radius is \( 2 \pi \) units, this is equivalent to stating that the unit current on the electromagnetic C.G.S. system is a current such that unit ampere produces a magnetic pole of unit magnetic moment at a unit distance apart.

Another definition, called the electrostatic unit of current, is as follows: Let any conductor be charged with electricity and discharged through a thin wire at such a rate that one electrostatic unit of quantity (see ELECTROSTATICS) flows past any section of the wire in one unit of time. The electromagnetic unit of current defined as above is \( 3 \times 10^{10} \) times larger than the electrostatic unit.

In the selection of a practical unit of current it was considered that the electromagnetic unit was too large for most purposes, whilst the electrostatic unit was too small; hence a practical unit of current called a ampere was selected, intended originally to be \( 1/10 \) of the absolute electromagnetic C.G.S. unit of current as above defined. The practical unit of current, called the international ampere, is, however, legally defined at the present time as the continuous unidirectional current which, when passed through a certain amount of silver nitrate solution in one second on the cathode or negative pole of a galvanometer of 28 of a gramme of silver. There is reason to believe that the international unit is smaller by about one part in a thousand, or perhaps by one part in 800, than the theoretical ampere defined as \( 1/10 \) part of the absolute electromagnetic unit. A periodic or alternating current is said to have a value of \( i \) ampere if when passed through a fine wire it produces in the same time the same heat as a unidirectional continuous current of \( i \) amperes as above electrochemically defined. In the case of a simple periodic alternating current having a simple wave form, the maximum value is equal to that of the e.i.e.i.t. continuous current multiplied by \( \sqrt{2} \). This e.i.e.i.t. continuous current is called the effective or root-mean-square (R.M.S.) value of the alternating one.

Resistance. A current flows in a circuit in virtue of an electro motive force (E.M.F.), and the numerical relation between the current and E.M.F. is determined by three qualities of the circuit called respectively, its resistance (R), conductance (L), and capacity (C). If we limit our consideration to the case of continuous unidirectional conduction currents, then the relation between current and E.M.F. is defined by Ohm's law, which states that the numerical value of the current is obtained as the quotient of the electromotive force by a certain constant of the circuit called its resistance, which is a function of the geometrical form of the circuit, of its nature, i.e., material, and of its temperature, but independent of the electromotive force or current. The resistance (R) is measured in units called ohms and the electromotive force in volts (V); hence for a continuous current the value of the current in amperes (A) is obtained as the quotient

---

\[ i = \frac{V}{R} \]

---

of the electromotive force acting in the circuit reckoned in volts by the resistance in ohms, or \( A = \frac{V}{R} \). Ohm established his law by experiments, and in the manner on which J. B. J. Fourier based his investigations on the uniform motion of heat in a conductor. As a matter of fact, however, Ohm's law merely states the direct proportionality of steady current to steady electromotive force in a circuit, and asserts that this ratio is governed by the numerical value of a quality of the conductor, called its resistance, which is independent of the current, provided that a correction is made for the change of temperature produced by the current. Our belief, however, in its universality and accuracy rests upon the close agreement between deductions made from it and observational results, and although it is not derivable from any more fundamental principle, it is yet one of the most certainly ascertained laws of electromotricity.

Ohm's law not only applies to the circuit as a whole but to any part of it, and provided the part selected does not contain a source of electromotive force it may be expressed as follows: The difference of potential (P.D.) between any two points of a circuit including a resistance R, but not including any source of electromotive force, is proportional to the product of the resistance and the current in the element, provided the conductor remains at the same temperature and the current is constant and unidirectional. If the current is varying we have, however, to take into account the electromotive force (E.M.F.) produced by this variation, and the product P is then equal to the difference between the observed P.D. and the induced E.M.F.

The equation defines the resistance of a circuit by saying that it is that physical quality of it in virtue of which energy is dissipated as heat in the circuit when a current flows through it. The power communicated to any electric circuit when a current \( i \) is created in it by a continuous unidirectional electromotive force \( E \) is equal to \( Ei \), and the energy dissipated as heat in that circuit by the conductor in a small interval of time \( dt \) is measured by \( Ei \, dt \). Since by Ohm's law \( E = RI \), where R is the resistance of the circuit, it follows that the energy dissipated as heat per unit of time in any circuit is numerically represented by \( R^2i^2 \), and therefore the resistance is measured by the heat produced per unit of current, provided the current is unvarying.

**Inductance**—As soon as we turn our attention, however, to alternating or periodic currents we find ourselves compelled to take into account another quality of the circuit, called its "inductance." This may be defined as that quality in virtue of which energy is stored in connection with the circuit in a magnetic form. It can be experimentally shown that a current cannot be created instantaneously in a circuit by any finite electromotive force, and that when once created it cannot be annihilated instantaneously. The circuit possesses a quality analogous to the inertia of matter. If a current \( i \) is flowing in a circuit at any moment, the energy stored up in connection with the circuit is measured by \( iL^2 \), where \( L \) is the inductance of the circuit, is related to the current in the same manner as the quantity called the mass of a body is related to its velocity in the expression for the ordinary kinetic energy, viz. \( \frac{1}{2}mv^2 \). The rate at which this conserved energy varies with the current is called the "electrokinetic momentum" of this circuit (=Ld). Physically interpreted this quantity signifies the number of lines of magnetic flux due to the current itself which are self-linked with its own circuit.

**Magnetic Force and Electric Currents**—In the case of every circuit conveying a current there is a certain magnetic force (see MAGNETISM) at external points which can in some instances be calculated. Laplace proved that the magnetic force due to an element of length ds of a circuit conveying a current I at a point P at a distance r from the element is expressed by \( 2\pi iR \sin \theta \), where \( \theta \) is the angle between the direction of the current element and that drawn between the element and the point. This force is in a direction perpendicular to the radius vector and to the plane containing it and the element of current. Hence the determination of the magnetic force due to any circuit is reduced to a summation of the effects due to all the elements of length. For instance, the magnetic force at the centre of a circular circuit of radius r carrying a steady current I is \( 2\pi iR \), since all elements are at the same distance from the centre. In the same manner, if we take a point in a line at right angles to the plane of the circle through its centre and at a distance d, the magnetic force along this line is expressed by \( \pi d^2(I/r^2d) \). Another important case is that of an infinitely long straight current. By summing up the magnetic force due to each element at any point P outside the continuous straight current I, and at a distance d from it, we can show that it is equal to \( \pi dI \) or is inversely proportional to the distance of the point from the wire.

In the above formula the current I is measured in absolute electromagnetic units. If we reckon the current in amperes A, then \( I = A/\pi \).

It is possible to make use of this last formula, coupled with an experimental fact, to prove that the magnetic force due to an element of current varies inversely as the square of the distance. If a flat circular disk is suspended so as to be free to rotate round a straight current which passes through its centre, and two bar magnets are placed on it with their axes in line with the current, it is found that the disk has no tendency to rotate round the current. This proves that the force on each magnetic pole is inversely as its distance from the current. But it can be shown that this law of action of the whole infinitely long straight current is a mathematical consequence of the fact that each element of the current exerts a magnetic force which varies inversely as the square of the distance. If the current flows N times round the circuit instead of once, we have to insert NA/\( \pi \)o in place of I in all the above formulas. The quantity NA is called the "ampere-turns" on the circuit, and it turns out that the magnetic field at any point outside a circuit is proportional to the ampere-turns on it and to a function of its geometrical form and the distance of the point.

There is therefore a distribution of magnetic force in the field of every current-carrying conductor which can be delineated by lines of magnetic force and rendered visible to the eye by iron filings (see MAGNETISM). If a copper wire is passed vertically through a hole in a card on which iron filings are sprinkled, and a strong electric current is sent through the circuit, the filings arrange themselves in concentric circular lines making visible the paths of the lines of magnetic force (fig. 3). In the same manner, by passing a circular wire through a card and sending a strong current through the wire we can employ iron filings to delineate for us the form of the lines of magnetic force (fig. 4).

In all cases a magnetic pole of strength M, placed in the field of an electric current, is urged along the lines of force with a mechanical force equal to MH, where H is the magnetic force. If then we carry a unit magnetic pole against the direction in which it would naturally move we do work. The lines of magnetic force embracing a current-carrying conductor are always loops or endless lines.

The work done in carrying a unit magnetic pole once round a circuit conveying a current is called the "line integral of magnetic force along that path." If, for instance, we carry a unit pole in a circular path of radius r once round an infinitely long straight filamentary current I, the line integral is 4\( \pi \)I. It is easy to prove electrically that this is a general law, and that if we have any currents flowing in a conductor the line integral of magnetic force taken once round a path linked with the current circuit is 4\( \pi \) times the total current flowing through the circuit. Let us apply this to the case of an endless solenoid. If a copper wire insulated or covered with cotton or silk is twisted round a thin rod so as to make a close spiral, this

![Fig. 3](image_url)

![Fig. 4](image_url)
forms a "solenoid," and if the solenoid is bent round so that its two ends come together we have an endless solenoid. Consider such a solenoid of length 21 and N turns. If the conductor is a thin endless solenoid the axial magnetic force is therefore $4x$ times the current-turns per unit length of the solenoid. This holds good also for a long straight solenoid provided its length is large compared with its diameter. The magnetic force in the interior is constant and the lines of force therefore parallel. The magnetic force at a point outside a conductor conveying a current can by various means be measured or compared with some other standard magnetic forces, and it becomes then a means of measuring the current. Instruments called galvanometers and ammeters for the most part operate on this principle.

**Thermal Effects of Currents.**—J. P. Joule proved that the heat produced by a constant current in a given time is a wire having a constant resistance is proportional to the square of the strength of the current. This is known as Joule's law, and it follows, as already shown, as an immediate consequence of Ohm's law and the fact that the power dissipated electrically in a conductor, when an electromotive force $E$ is applied to its extremities, producing thereby a current $I$ in it, is equal to $EI$.

If the current is alternating or periodic, the heat produced in any time $T$ is obtained by taking the sum at equidistant intervals of time of the squares of the quantities of heat $dQ$ for a small interval of time $dt$ and of the current $i$ at that instant. The quantity $T^{-1} \int_0^T i^2 dt$ is called the mean-square-value of the variable current, $i$ being the instantaneous value of the current, that is, its value at a particular instant or during a very small interval of time $dt$. The square root of the above quantity, or

$$[T^{-1} \int_0^T i^2 dt]^{1/2}$$

is called the root-mean-square-value, or the effective value of the current, and is denoted by the letters R.M.S.

Currents have equal heat-producing power in conductors of identical resistance when they have the same R.M.S. values. Hence periodic or alternating currents can be measured as regards their R.M.S. value by ascertaining the continuous current which produces in the same time the same heat in the same conductor as the periodic current considered. Current measuring instruments depending on this fact, called hot-wire ammeters, are in common use, especially for measuring alternating currents. The maximum value of the periodic current can only be determined from the R.M.S. value when we know the wave form of the current. The thermal effects of electric currents in conductors are dependent upon the production of energy, and the state of equilibrium between the heat produced electrically in the wire and the cause operative in removing it. If an ordinary round wire is heated by a current it loses heat, (1) by radiation, (2) by air convection or cooling, and (3) by conduction of heat out of the ends of the wire. Generally speaking, the greater part of the heat removal is effected by radiation and convection.

If a round sectioned metallic wire of uniform diameter $d$ and length $l$ made of a material of resistivity $\rho$ has a current $I$ passed through it, the heat in watts produced in any time $t$ seconds is given by the expression $\frac{\rho I^2 l}{4 \pi d^2}$, where $d$ and $l$ must be measured in centimeters and $\rho$ in absolute C.G.S. electromagnetic units. The factor $t$ enters because one may get the expression $\frac{\rho I^2 l}{4 \pi d^2}$ absolute electromagnetic C.G.S. units (see Units, Physical). If the wire has an emissivity $\varepsilon$, by which is meant that $\varepsilon$ units of heat reckoned in joules or watt-seconds of the quantity of heat per second from unit of surface, then the power removed by radiation in the time $t$ is expressed by $\varepsilon \delta t$. Hence when thermal equilibrium is established we have $4 \pi \frac{\rho I^2 l}{4 \pi d^2} = \varepsilon \delta t$. If the diameter of the wire is reckoned in mils (1 mil = .001 in.), and if we take $t$ to have a value $0.1$, an emissivity which will generally bring the wire to about 60° C. we can put the above formula in the following form for circular sectioned copper, iron or aluminum wires, viz.

$$A = \frac{\sqrt{2}}{500} \text{ for copper wires}$$

$$A = \frac{\sqrt{2}}{1000} \text{ for iron wires}$$

$$A = \frac{\sqrt{2}}{2000} \text{ for platinoid wires.}$$

These expressions give the ampere value of the current which will bring bare, straight or loosely coiled wires of $d$ mils in diameter to about 60° C. when the steady state of temperature is reached.

Thus, for instance, a bare straight copper wire 50 mils in diameter (+0.05 in.) will be brought to a steady temperature of about 60° C. if a current of $\sqrt{2}/500 = 0.25$ ampere (nearly) is passed through it, whilst a current of $\sqrt{2}/2000 = 0.05$ ampere would bring a platinum wire to about the same temperature.

A wire has therefore a certain safe current-carrying capacity which is determined by its specific resistance and emissivity, the latter being fixed by its form, surface and surroundings. The current increases with the temperature, else no state of thermal equilibrium could be reached. It has been found experimentally that whilst for fairly thick wires from 8 to 60 mils in diameter the safe current varies approximately as the $1/2$-th power of the diameter, for fine wires of 1 to 3 mils it varies more nearly as the diameter.

**Action of one Current on Another.**—The investigations of Ampère in connexion with electric currents are of fundamental importance in electrokinetics. Starting from the discovery of Oersted, Ampère made the correlative fact that not only is there a mechanical action between a current and a magnet, but that two conductors conveying electric currents exert mechanical forces on each other. Ampère devised ingenious methods of making one portion of a circuit movable so that he might observe effects of attraction or repulsion between this circuit and some other fixed current. He employed for this purpose an astatic circuit B, consisting of a wire bent into a double rectangle around which a current flowed first in one and then in the opposite direction (fig. 5). In this way the circuit was removed from the action of the earth's magnetic field, and yet one portion of it could be submitted to the action of any other circuit C. The astatic circuit was pivoted by suspending it in a mercury cups q, p, one of which was in electrical connexion with the tubular support A, and the other with a strong insulated wire passing up it.

Ampère devised certain crucial experiments, and the theory deduced from them is based upon four facts and one assumption. 1. He showed (1) that wire conveying a current bent back on itself produced no action upon a proximate portion of a movable astatic circuit; (2) that if the bending was not abrupt but to the outgoing straight wire the circuit produced no action on the movable one, showing that the effect of an element of the circuit was proportional to its projected length; (3) that a closed circuit cannot cause motion in an element of another circuit free to move in the direction of its length; and (4) that the action of two circuits on one and the same movable circuit was null if one of the two fixed circuits was $s$ times greater than the other but $s$ times further removed from the movable circuit. From this last experiment by an ingenious line of reasoning he proved that the action of an element of current on another element of current varies inversely as a square of their distance. These experiments enabled him to construct a mathematical expression of the law of action between two elements of conductors conveying currents. They also enabled him to prove that an element of current may be resolved like a force into components in different directions, also that the force produced by any element of the circuit on an element of current was perpendicular to the line joining the elements and inversely as the square of their distance. Also he showed that this force was an attraction if the currents in the elements were in the same direction, but a repulsion if they were in opposite directions. From these experiments and deductions from them he built up a complete formula for the action of one element of a current of length $ds$
of one conductor conveying a current I upon another element dS' of another circuit conveying another current I' the elements being at a distance apart equal to r.

\[ f = 2\pi \rho \text{ Icos } \theta \text{ cos } \phi \text{ dS} \]

This law, together with that of Laplace already mentioned, viz., that the magnetic force due to an element of length dS of a current I at a distance r, the element making an angle \( \theta \) with the radius vector \( \rho \) is IdS sin \( \theta / \rho \), constitutes the fundamental laws of electrodynamics.

Ampère applied these with great mathematical skill to elucidate the mechanical actions of currents on each other, and experimentally confirmed the following deductions: (1) Currents in parallel circuits, flowing in the same direction, attract each other, but if in opposite directions repel each other. (2) Currents in wires meeting at an angle attract each other more into parallelism if both flow either to or from the angle, but repel each other more widely apart if they are in opposite directions. (3) A current in a small circular conductor exerts a magnetic force in its centre perpendicular to its plane and is in all respects equivalent to a magnetic shell or a thin circular disk of steel so magnetized that one face is a north pole and the other a south pole, the product of the area of the circle and the current, flowing in it, determining the magnetic moment of the element. (4) A closely wound spiral current is equivalent as regards external magnetic force to a polar magnet, such a circuit being called a finite solenoid. (5) Two finite solenoid circuits act on each other like two magnets, exhibiting actions of attraction or repulsion between their ends.

Ampère's theory was wholly built up on the assumption of action at a distance between elements of conductors conveying the electric currents. Faraday's researches and the discovery of the fact that the insulating medium is the real seat of the operations necessitates a change in the point of view from which we regard the facts discovered by Ampère. Maxwell showed that in any field of magnetic force there is a tension along the lines of force and a pressure at right angles to them; in other words, lines of magnetic force are like stretched elastic threads which tend to contract. If, therefore, two conductors lie parallel and have currents in them in the same direction they are impressed by a certain number of lines of magnetic force which pass round the two conductors, and it is the tendency of these to contract which draws the circuits together. If, however, the currents are in opposite directions then the lateral pressure of the similarly contracted lines of force between them pushes the circuits apart. Ampère's empirical law that the attraction of two parallel conductors was made by W. E. Weber in inventing the electro-dynamometer, and later Lord Kelvin devised amperes' balances for the measurement of electric currents based on the attraction between coils conveying electric currents.

Induction of Electric Currents.—Faraday in 1831 made the important discovery of the induction of electric currents (see Electromagnetism). If two conductors are placed parallel to each other, and a current in one of them, called the primary, starts or stops or changes in strength, every such alteration causes a transitory current to appear in the other circuit, called the secondary. This is due to the fact that as the primary current increases or decreases, its own embracing magnetic field alters, and lines of magnetic force are added to or subtracted from its fields. These lines do not appear instantly in their place at a distance, but are propagated out from the wire with a velocity equal to that of light; hence in their outward progress they cut through the secondary circuit, just as ripples made on the surface of water in a lake by throwing a stone on to it expand and cut through a stick held vertically in the water at a distance from the place of origin of the ripples. Faraday confirmed this view of the phenomena by proving that the mere motion of a wire transversely to the lines of magnetic force of a permanent magnet gave rise to an induced electromotive force in the wire.

He embraced all the facts in the single statement that if there be any circuit which by movement in a magnetic field, or by the creation or change in magnetic fields round it, experiences a change in the number of lines of force linked with it, then an electromotive force is set up in that circuit which is proportional at any instant to the rate at which the total magnetic flux linked with it is changing. Hence if \( L \) represents the total number of lines of magnetic force linked with a circuit of length \( dL \), then \(-N(d\Phi/dt)\) represents the electromotive force set up in that circuit. The operation of the induction coil (p.8) and the transformer (p.8) are based on this discovery. Faraday also found that if a copper disk A (fig. 6) is rotated between the poles of a magnet NO so that the disk moves with its plane perpendicular to the lines of magnetic force of the field, it has created in it an electromotive force directed from the centre to the edge or vice versa. The action of the dynamo (p.8) depends on similar processes, viz., the cutting of the lines of magnetic force of a constant field produced by certain magnets by certain moving conductors called armature bars or coils in which an electromotive force is thereby created.

In 1834 H. F. E. Lenz enunciated a law which connects the mechanical actions between electric circuits discovered by Ampère and the induction of electric currents discovered by Faraday. It is as follows: If a constant current flows in a primary circuit \( P \), and if by motion of \( P \)'s secondary current is created in a neighbouring circuit \( S \), the direction of the secondary current will be such as to oppose the relative motion of the circuits. Starting from this, F. E. Neumann founded a mathematical theory of induced currents, discovering a quantity \( M \), called the "potential of one circuit on another," or generally their "coefficient of mutual induction." Mathematically \( M \) is obtained by taking the sum of all such quantities as \( \int dS \text{ cos } \theta / \rho \), where \( dS \text{ and } dS' \) are the elements of length of the two circuits, \( r \) is their distance, and \( \theta \) is the angle which they make with one another; the summation or integration must be extended over every possible pair of elements. If we take pairs of elements in the same circuit, then Neumann's formula gives us the coefficient of self-induction of the circuit or the potential of the circuit on itself. For the results of such calculations on various forms of circuits the reader must be referred to special treatises.

H. von Helmholz, and later Lord Kelvin, showed that the facts of induction of electric currents discovered by Faraday could have been predicted from the electrodynamic action discovered by Ampère assuming the principle of the conservation of energy. Helmholz takes the case of a circuit of resistance \( R \) in which acts an electromotive force due to a battery or thermopile. Let a magnet be in the neighbourhood, and the potential of the magnet on the circuit be \( V \), so that if a current \( I \) existed in the circuit the work done on the magnet in the time \( dt \) is \( I(E-V)dt \). The source of electromotive force supplies in the time \( dt \) work equal to \( El dt \), and according to the law energy is dissipated equal to \( IR^2 dt \). Hence, by the conservation of energy,

\[ El dt = IR^2 dt + (E-V)dt \]

If then \( E = 0 \), we have \( I = -(dV/dt)/R \), or there will be a current due to an induced electromotive force expressed by \(-dV/dt\). Hence if the magnet moves, it will create a current in the wire provided that such motion changes the potential of the magnet with respect to the circuit. This is the effect discovered by Faraday.

Oscillatory Currents.—In considering the motion of electricity in conductors we find it useful to consider the process of the discharge of a condenser or Leyden jar (p.8). This problem was first mathematically treated by Lord Kelvin in 1853 (Phil. Mag., 1853, 5, p. 292).

If a conductor of capacity \( C \) has its terminals connected by a wire of resistance \( R \) and inductance \( L \), it becomes important to consider...
ELECTROKINETICS

the subsequent motion of electricity in the wire. If \( Q \) is the quantity of electricity in the condenser initially, and \( q \) that at any time \( t \) after completing the circuit, then the energy stored up in the condenser at that instant is \( \frac{q^2}{2C} \), and the energy associated with the circuit is \( \frac{1}{2} (dq/dt)^2 \), and the rate of dissipation of energy by resistance is \( R (dq/dt)^2 \), since \( dq/dt \) is the discharge current. Hence we can construct an equation of energy which expresses the fact that at any instant the power given out by the condenser is partly stored in the circuit and partly dissipated as heat in it. Mathematically this is expressed as follows:

\[
\frac{dq}{dt} = -\frac{q^2}{2C} + \frac{1}{2} (dq/dt)^2 + R (dq/dt)^2
\]

or

\[
\frac{dq}{dt} + \frac{q}{C} = \frac{1}{(R/C)^2} \frac{d^2 q}{dt^2}
\]

The above equation has two solutions according as \( R^2/C^2 \) is greater or less than \( 1/LC \). In the first case the current \( i \) in the circuit can be expressed by the equation

\[
i = \frac{Q}{a+\beta} - \frac{e^{-\beta t}}{\beta} \sin \beta t
\]

where \( a = R/2L \), \( \beta = \sqrt{1/LC} \), \( Q \) is the value of \( q \) when \( t = 0 \), and \( \epsilon \) is the base of Napierian logarithms; and in the second case by the equation

\[
i = \frac{Q}{a+\beta} - \frac{e^{-\beta t}}{\beta} \cos \beta t
\]

These expressions show that in the first case the discharge current of a short circuit is always alternating, and in the second unidirectional. However, the current in an oscillatory current gradually decreasing in amplitude, the frequency \( n \) of the oscillation being given by the expression

\[
n = \frac{1}{2\pi} \sqrt{\frac{1}{LC} \frac{R^2}{4\beta^2}}
\]

In those cases in which the resistance of the discharge circuit is very small, the expression for the frequency \( n \) and for the time of oscillation \( T \) take the simple forms \( n = \frac{2\pi}{\sqrt{LC}} \), or \( T = \pi n = \frac{\pi}{2\sqrt{LC}} \).

The above investigation shows that if we construct a circuit consisting of a condenser and inductance placed in series with one another, such circuit has a natural electrical period of time of its own in which the electrical charge in it oscillates if disturbed. It may therefore be compared with a pendulum of any kind which when displaced oscillates with a period of time depending on its inertia and its restoring force.

The study of these electrical oscillations received a great impetus after H. R. Hertz showed that when taking place in electric circuits of a certain kind they create electromagnetic waves (see ELECTRIC WAVES) in the dielectric surrounding the oscillator, and an additional interest was given to them by their application to telegraphy. If a Leyden jar and a circuit of low resistance but some inductance in series with it are connected across the secondary spark gap of an induction coil, then when the coil is set in motion we have a series of bright noisy sparks, each of which consists of a train of oscillatory electric discharges from the jar. The condenser becomes charged as the secondary electromotive force of the coil is treated at each break of the primary current, and when the potential difference of the condenser coatings reaches a certain value determined by the spark-ball distance a discharge happens. This discharge, however, is not a single movement of electricity in one direction but an oscillatory motion with gradually decreasing amplitude. If the oscillatory spark is photographed on a revolving plate or a rapidly moving film, we have evidence in the photograph that such a spark consists of numerous intermittent sparks gradually becoming feeble. As the coil continues to operate, these trains of electric discharges take place at regular intervals. We can cause \( n \) trains of oscillatory currents in one circuit to induce similar oscillations in a neighboring circuit, and thus construct an oscillation transformer or high frequency induction coil.

**Alternating Currents.**—The study of alternating currents, which began to attract great attention towards the end of the 19th century by reason of their application in electrotechnics and especially to the transmission of power. A circuit in which a simple periodic alternating current flows is called a single-phase circuit. The important difference between such a form of current flow and steady current flow arises from the fact that if the circuit has inductance then the periodic electric current in it is not in phase with the terminal potential difference or electromotive force acting in the circuit, but the current lags behind the electromotive force by a certain fraction of the periodic time called the "phase difference." If two alternating currents having a fixed difference in phase flow in two connected separate but related circuits, the two are called a two-phase current. If three or more single-phase currents preserving a fixed difference of phase flow in various parts of a connected circuit, the whole taken together forms a polyphase current. A single-phase current is a vector quantity, that is, has direction as well as magnitude, it can most conveniently be represented by a line denoting its maximum value, and if the alternating current is a simple periodic current then the root-mean-square or effective value of the current is obtained by dividing the maximum value by \( \sqrt{2} \).

Accordingly when we have an electric circuit or circuits in which there are simple periodic currents we can draw a vector diagram, the lines of which represent the relative magnitudes and phase differences of these currents.

A vector can most conveniently be represented by a symbol such as \( a+ib \), where \( a \) stands for any length of a units measured horizontally and \( b \) for a length of units measured vertically, and the symbol \( i \) is a sign of perpendicularity, and equivalent analytically to \( \sqrt{-1} \). If \( E \) represents the root-mean-square value (maximum value) acting in a circuit of resistance \( R \) and inductance \( L \) and frequency \( n \), and if the current considered as a vector is represented by \( I \), it is easy to show that a vector equation exists between these quantities as follows:

\[
E = R I + \omega n L I
\]

Since the absolute magnitude of a vector \( a+ib \) is \( \sqrt{a^2+b^2} \) it follows that considering merely magnitudes of current and electromotive forces we have to consider the laws which govern the flow of currents in linear conductors (wires), in plane conductors (sheets), and throughout the mass of a material conductor. In the first case consider the collection of a number of parallel wires, if the wires are highly conductive, such a collection can be made to form a network of conductors. The network consists of a number of conductors joining certain points and forming meshes. In each conductor a current may exist, and along such conductor there is a fall of potential, or an active electromotive force may be acting in it. Each conductor has a certain resistance. To find the current in each conductor when the individual resistances and electromotive forces of the circuit are given, proceed as follows: Consider any one mesh. The sum of all the electromotive forces which exist in the branches bounding that mesh must be equal to the sum of all the products of the resistance into the currents flowing along those, or \( I(x) = \sum I \).

If we consider each mesh as traversed by imaginary curvilinear currents all circulating in the same direction, the real currents are the sums or differences of these imaginary cyclic currents in each branch. Hence we may assign to each mesh a cyclic symbol \( x, y, z, &c \), and form a cyclic equation. Write down the cyclic symbol for a mesh and prefix as coefficient the sum of all the resistances which bound the cycle, then subtract for each of the symbols of each adjacent cycle, each multiplied by the value of the bounding or common resistances, and equate this sum to the total electromotive force acting round the cycle and thus if \( x, y, z \) are not the difference or electromotive force bounding the mesh \( x \) and \( y \) and \( z \) are separated from it by the meshes \( y \) and \( z \). E an electromotive force in the branch, then

we have formed the cycle equation \( x(a + b + c) - by - ce = E \). For each mesh a similar equation may be formed. Hence we have as many linear equations as there are meshes and we obtain the solution for each cycle symbol, and therefore for the current in each branch. The solution giving the current in such branch of the network is therefore always in the form of a quotient of two determinants. The solution of the well-known problem of finding the current in the galvanometer circuit of the arrangement of linear conductors called Wheatstone's Bridge is thus easily obtained.

For all we call the cycles (see Fig. 7) \( P, Q, R, S, G, B, C \), and the mesh voltages \( P, Q, R, S, G, B, C \), and if \( E \) be the electromotive force in the battery circuit, we have the cycle equation:

\[
(P + G + R)(x + y) - Gy - Ra = 0,
\]

\[
(Q + G + S)(x + y) - Gx - Sz = 0,
\]

\[
(R + S + B)(x + y) - Rx = 0,
\]

\[
(Sy + E).
\]

From these we can easily obtain the solution for \( (x + y) = x \), which is the current through the galvanometer circuit in the form:

\[
\alpha = E(PS - QR).
\]

where \( \alpha \) is a certain function of \( P, Q, R, S, G, B, C \).

**Currents as Skeets.**—In the case of current flow in plate sheets, we have to consider certain points called sinks at which the current flows into the sheet, and certain points called sinks at which it leaves. We may investigate, first, the simple case of one source and one sink in a sheet of thickness \( t \). Let \( E \) be the electromotive force. Take any point \( P \) in the plane at distances \( R \) and \( r \) from the source and sink respectively. The potential \( V \) at \( P \) is obviously given by:

\[
V = \frac{Q}{2\pi\kappa} \log \left(\frac{r}{\rho}\right)
\]

where \( Q \) is the quantity of electricity supplied by the source per second. Hence the equation to the equipotential curve is \( r = \frac{Q}{\pi\kappa\log(\rho)} \).

If we take a point half-way between the sink and the source as the origin of a system of rectangular co-ordinates, and if the distance between the source and the sink is equal to the thickness of the sheet, then the equipotential line is:

\[
\theta = \frac{\pi}{2} + \left(\frac{x - r}{\rho}\right)^2 = \frac{\pi}{2} + \left(\frac{x - r}{\rho}\right)^2 = \text{a constant}.
\]

This is the equation of a family of circles having the axis of \( y \) for a common radical axis, one set of circles surrounding the sink and another set of circles surrounding the source. In order to discover the form of the stream of current lines we have to determine the orthogonal trajectories to this family of coaxial circles. It is easy to show that the orthogonal trajectory of the system of circles is another system of circles all passing through the sink and the source, and as a corollary of this fact, that the electric resistance of a circular disk of uniform thickness is the same between any two points taken anywhere on its circumference as between source and sink. These equipotential lines may be delineated experimentally by attaching the terminals of a battery or batteries to small wires which touch at various places a sheet of tinfoil. The tinfoil may then be placed on the tinfoil, and one may be kept stationary and the other may be moved about, so that the galvanometer is not traversed by any current. The moving terminal then traces out an equipotential curve. If there are \( n \) sinks and sources in a plane conducting sheet, and if \( r, r', r'' \) are the distances of any point from the sinks, and \( t, t', t'' \) the distances of the sources, then:

\[
r = r, r', r'' = \text{a constant},
\]

is the equation to the equipotential lines. The orthogonal trajectories or stream lines have the equation:

\[
\theta = \text{a constant},
\]

where \( \theta \) and \( \theta' \) are the angles which the lines drawn from any point in the plane to the sink and corresponding source make with the line joining that sink and source. Generally it may be shown that if there are any number of sinks and sources in an infinite plane-conducting sheet, and if \( r, \theta \) are the polar co-ordinates of any one, then the equation to the equipotential surfaces is given by the equation:

\[
A \log(r) = \text{a constant},
\]

where \( A \) is a constant; and the equation to the stream or current lines is:

\[
\theta = \text{a constant}.
\]

In the case of electric flow in three dimensions the electric potential must satisfy Laplace's equation, and a solution is therefore found in the form \( 2A(\theta) = \theta \) is a constant, as the equation to an equipotential surface, where \( r \) is the distance of any point on that surface from a source or sink.

---

**Convection Currents.**—The subject of convection electric currents has risen to great importance in connexion with modern electrical investigations. The question whether a statically electrified body in motion creates a magnetic field is of fundamental importance. Experiments to settle it were first undertaken in the year 1876 by H. A. Rowland, at a suggestion of H. von Helmholtz. After preliminary experiments, Rowland's first apparatus for testing this hypothesis was constructed, as follows:—An ebonite disk was covered with radial strips of gold-leaf and placed between two other metal plates which acted as screens. The disk was then charged with electricity and set in rapid rotation. It was found to attract a delicately suspended pair of astatic magnetic needles hung in proximity to the disk just as would, by Oersted's rule, a circular electric current coincident with the periphery of the disk. Hence the statically-charged but rotating disk becomes in effect a circular electric current.

The experiments were repeated and confirmed by W. C. Röntgen (Wied. Ann., 1888, 35, p. 264; 1889, 40, p. 99) and by F. Himstedt (Wied. Ann., 1889, 38, p. 560). Later V. Cernjiew again repeated them and obtained negative results (Com. rend., 1900, 150, p. 1544, and 131, pp. 578 and 797, 1901, 132, pp. 327 and 1108). They were again very carefully re-conducted by H. Pender (Phil. Mag., 1901, 2, p. 179) and by P. E. Adams (id., ib., 285). Pender's work showed beyond a doubt the existence of a magnetic effect. Adams employed charged copper spheres rotating at a high speed in place of a disk, and was able to prove that the rotation of such spheres produces a magnetic field similar to one due to a circular current and agreeing numerically with the theoretical value. It has been shown by J. J. Thomson (Phil. Mag., 1881, 2, p. 230) and O. Heaviside (Electrical Papers, vol. ii. p. 205) that an electrified sphere, moving with a velocity \( v \) and carrying a quantity of electricity \( q \), should produce a magnetic force \( H \), at a point at a distance \( \rho \) from the centre of the sphere, equal to \( qv \sin \theta / \rho \), where \( \theta \) is the angle between the direction of \( \rho \) and the motion of the sphere. Adams found the field produced by a known electric charge rotating at a known speed had a strength not very different from that determined by the above formula. An observation recorded by R. W. Wood (Phil. Mag., 1903, 2, p. 699) provides a confirmatory fact. He noticed that if carbon-dioxide gas, strongly compressed in a steel bottle is allowed to escape suddenly the cold produced solidifies some part of the gas, and the issuing jet is full of particles of carbon-dioxide snow. These by friction against the nozzle are electrified positively. Wood caused the jet of gas to pass through a glass tube \( 25 \) mm. in diameter, and found that these particles of electrified snow were blown through it with a velocity of \( 3000 \) ft. a second. Moreover, he found that a magnetic needle hung near the tube was deflected as if held near an electric current. Hence the positively electrified particles in motion in the tube create a magnetic field round it.

**Nature of an Electric Current.**—The question, What is an electric current? is involved in the larger question of the nature of electricity. Modern investigations have shown that negative electricity is identical with the electron or corpuscles which are components of the chemical atom (see Matter and Electricity). Certain lines of argument lead to the conclusion that a solid conductor is not only composed of chemical atoms, but that there is a certain proportion of free electrons present in it, the electronic density or number per unit of volume being determined by the material, its temperature and other physical conditions. If any cause operates to add or remove electrons at one point there is an immediate diffusion of electrons to re-establish equilibrium, and this electronic movement constitutes an electric current. This hypothesis explains the results for the identity between the laws of diffusion of matter, of heat and of electricity. Electromotive force is then any cause making or tending to make an inequality of electronic density in conductors, and may arise from differences of temperature, i.e. thermoelectromotive force.
ELECTROLYTIC—ELECTROLYSIS (see THERMOELECTRICITY), or from chemical action when part of the circuit is an electrolytic conductor, or from the movement of lines of magnetic force across the conductor.

ELECTROLYTIC, a fixture, usually pendant from the ceiling, for holding electric lamps. The word is analogous to chandelier, from which indeed it was formed.

ELECTROLYSIS (formed from Gr. ηλεκτρον, to loosen). When the passage of an electric current through a substance is accompanied by definite chemical changes which are independent of the heating effects of the current, the process is known as electrolysis; and the substance is called an electrolyte. As an example we may take the case of a solution of a salt such as copper sulphate in water, through which an electric current is passed between copper plates. We shall then observe the following phenomena: (1) The bulk of the solution is unaltered, except that its temperature may be raised owing to the usual heating effect which is proportional to the square of the strength of the current. (2) The copper plate by which the current is said to enter the solution, i.e. the plate attached to the so-called positive terminal of the battery or other source of current, dissolves away, the copper going into solution as copper sulphate. (3) Copper is deposited on the surface of the other plate, being obtained from the solution. (4) Oxygen is evolved in consequence of the electrolysis. In the case we have chosen, the solution becomes stronger near the anode, or electrode at which the current enters, and weaker near the cathode, or electrode at which it leaves the solution. If, instead of using copper electrodes, we take plates of platinum, the copper is still deposited on the cathode; but, instead of the anode dissolving, free sulphuric acid appears in the neighbouring solution, and oxygen gas is evolved at the surface of the platinum plate.

With other electrolytes similar phenomena appear, though the primary chemical changes may be masked by secondary actions. Thus, with a dilute solution of sulphuric acid and platinum electrodes, hydrogen gas is evolved at the cathode, while, as the result of a secondary action on the anode, sulphuric acid is there re-formed, and oxygen gas evolved. Again, with the solution of a salt such as sodium chloride, the sodium, which is primarily liberated at the cathode, decomposes the water and evolves hydrogen, while the chlorine may be evolved as such, may dissolve the anode, or may liberate oxygen from the water, according to the nature of the plate and the concentration of the solution.

Early History of Electrolysis.—Alessandro Volta of Pavia discovered the electric battery in the year 1800, and thus placed the means of maintaining a steady electric current in the hands of investigators, who, before that date, had been restricted to the study of the isolated electric charges given by frictional electric machines. Volta's cell consists essentially of two plates of different metals, such as zinc and copper, connected by an electrolyte such as a solution of salt or acid. Immediately on its discovery intense interest was aroused in the new invention, and the chemical effects of electric currents were speedily detected. W. Nicholson and Sir A. Carlisle found that hydrogen and oxygen were evolved at the plates, S. P. Thompson, that the water of gold and platinum wires connected with the terminals of a battery and dipped in water. The volume of the hydrogen was about double that of the oxygen, and, since this is the ratio in which these elements are combined in water, it was concluded that the process consisted essentially in the decomposition of water. They also noticed that a similar kind of chemical action went on in the battery itself. Soon afterwards, William Cruickshank decomposed the magnesium, sodium, and ammonium chlorides, and precipitated silver and copper from their solutions—an observation which led to the process of electroplating. He also found that the liquid round the anode became acid, and that round the cathode alkaline. In 1804 W. Hisinger and J. J. Berzelius stated that neutral salt solutions could be decomposed by electricity; the acid appearing as one pole and the metal at the other. This observation showed that nascent hydrogen was not, as had been supposed, the primary cause of the separation of metals from their solutions, but that the action consisted in a direct decomposition into metal and acid. During the earliest investigation of the subject it was thought that, since hydrogen and oxygen were usually evolved, the electrolysis of solutions of acids and alkalies was to be regarded as a direct decomposition of water. In 1806 Sir Humphry Davy proved that the formation of acid and alkali when water was electrolysed was due to saline impurities in the water. He had shown previously that decomposition of water could be effected although the two poles were placed in separate vessels connected by moistened threads. In 1807 he decomposed potash and soda, previously considered to be elements; by passing the current from a powerful battery through the moistened solids, and thus isolated the metals potassium and sodium.

The electromotive force of Volta's simple cell falls off rapidly when the cell is used; and this phenomenon was shown to be due to the accumulation at the metal plates of the products of chemical changes in the cell itself. This reverse electromotive force of polarization is produced in all electrolytes when the passage of the current changes the nature of the electrodes. In batteries which use acids as the electrolyte, a film of acid tends to be deposited on the copper or platinum electrode; but, to obtain a current of definite electromotive force, several means were soon devised of preventing the formation of the film. Constant cells may be divided into two groups, according as their action is chemical (as in the Daniell cell, where the hydrogen is converted into water by an oxidizing agent placed in a porous pot around the carbon plate) or electrochemical (as in Daniell’s cell, where a copper plate is surrounded by a solution of copper sulphate, and the hydrogen; instead of being liberated, faces copper, which furnishes the positive force, solution).

Faraday's Laws.—The first exact quantitative study of electrolytic phenomena was made about 1830 by Michael Faraday (Experimental Researches, 1835). When an electric current flows round a circuit, there is no accumulation of electricity anywhere in the circuit, hence the current strength is everywhere the same; and we may picture the current as analogous to the flow of an incompressible fluid. Acting on this view, Faraday set himself to examine the relation between the flow of electricity round the circuit and the amount of chemical decomposition. He passed the current driven by a voltaic battery gmp (fig. 1) through two branches containing the two electrolytic cells A and B. The reunited current was then led through another cell C, in which the strength of the current must be the sum of those in the arms A and B. Faraday found that the mass of substance liberated at the electrodes in the cell C was equal to the sum of the masses liberated in the cells A and B. He also found that, for the same current, the amount of chemical action was independent of the size of the electrodes and proportional to the time that the current flowed. Regarding the current as a passage of a certain amount of electricity per second, it will be seen that the results
of all these experiments may be summed up in the statement that the amount of chemical action is proportional to the quantity of electricity which passes through the cell.

Faraday's next step was to pass the same current through different electrolytes in series. He found that the amounts of the substances liberated in each cell were proportional to the chemical equivalent weights of those substances. Thus, if the current be passed through dilute sulphuric acid between hydrogen electrodes, and through a solution of copper sulphate, it will be found that the mass of hydrogen evolved in the first cell is to the mass of copper deposited in the second as 1 is to 31-8. Now this ratio is the same as that which gives the relative chemical equivalents of hydrogen and copper, for 1 gramme of hydrogen and 31-8 grammes of copper unite chemically with the same weight of any acid radicle such as chlorine or the sulphuric group, SO₄. Faraday examined also the electrolysis of certain fused salts such as lead chloride and silver chlorate. Similar relations were found to hold and the amounts of chemical change to be the same for the same electric transfer as in the case of solutions.

We may sum up the chief results of Faraday's work in the statements known as Faraday's laws: The mass of substance liberated from an electrolyte by the passage of a current is proportional to the total quantity of strength known in electromagnetic units. It is found that the most accurate and convenient apparatus to use is a platinum bowl filled with a solution of silver nitrate containing about fifteen parts of the salt to one hundred of water. Into the solution dips a silver plate wrapped in silver paper, and the current is passed from the silver plate as anode to the bowl as cathode. The bowl is weighed before and after the passage of the current, and the increase gives the mass of silver deposited. The mean result of the best determinations shows that when a current of one ampere is passed for one second, a mass of silver is deposited equal to 0-00118 gramme. So accurate and convenient is this determination that it is now used conversely as a practical definition of the ampere, which (defined theoretically in terms of magnetic force) is defined practically as the current which in one second deposits 1-118 milligramme of silver.

The chemical equivalent of a substance, as determined by chemical experiments, to be 107-92, the result described as the electrochemical equivalent of an ion of unit chemical equivalent the value 1-096X 10⁻⁴. If, as is now usual, we take the equivalent weight of oxygen as our standard and call it 16, the equivalent weight of hydrogen is 1-008, and its electrochemical equivalent is 1-044X 10⁻⁴. The electrochemical equivalent of any other substance, whether element or compound, may be found by multiplying its chemical equivalent by 1-096X 10⁻⁴.

Chemical Nature of the Ions.—A study of the products of decomposition does not necessarily lead directly to a knowledge of the ions actually employed in carrying the current through the electrolyte. Since the electric forces are active throughout the whole solution, all the ions must come under its influence and therefore move, but their separation from the electrodes is determined by the electromotive forces needed to liberate them. Thus, as long as every ion of the solution is present in the layer of liquid next the electrode, the one which responds to the least electromotive force will alone be set free. When the amount of this ion in the surface layer becomes too small to carry all the current across the junction, other ions must also be used, and either they or their secondary products will appear also at the electrode. In aqueous solutions, for instance, a few hydrogen (H) and hydroxyl (OH) ions derived from the water are always present, and will be liberated if the other ions require a higher decomposition voltage and the current be kept so small that hydrogen and hydroxyl ions can be formed fast enough to carry all the current across the junction between solution and electrode.

The issue is also obscured in another way. When the ions are set free at the electrodes, they may unite with the substance of the electrode or with some constituent of the solution to form secondary products. Thus the hydroxyl mentioned above decomposes into water and oxygen, and the chlorine produced by the electrolysis of a chloride may attack the metal of the anode. This leads us to examine more closely the part played by water in the electrolysis of aqueous solutions. Distilled water is a very bad conductor, though, even when great care is taken to remove all dissolved bodies, there is evidence to show that some part of the trace of conductivity remanent is due to the water itself. By careful redistillation F. Kohlrausch has prepared water of which the conductivity compared with that of mercury was only 0-4X10⁻¹⁴ at 18°C. Even here some little impurity was present, and the conductivity of chemically pure water was estimated by thermodynamic reasoning as 0-6X10⁻¹⁴ at 18°C. As we shall see later, the conductivity of very dilute salt solutions is proportional to the concentration, that is, it is probable that in all such cases, practically all the current is carried by the salt. At the electrodes, however, the small quantity of hydrogen and hydroxyl ions from the water are liberated first in cases where the ions of the salt have a higher decomposition voltage. The water being present in excess, the hydrogen and hydroxyl are re-formed at once and therefore are set free continuously. If the current be so strong that new hydrogen and hydroxyl ions cannot be formed in time, other substances are liberated; in a solution of sulphuric acid a strong current will evolve sulphur dioxide, the more readily as the concentration of the solution is increased. Similar phenomena are seen in the case of a solution of hydrochloric acid. When the solution is weak, hydrogen and oxygen are evolved; but, as the concentration is increased, and the current raised, more and more chlorine is liberated.

An interesting example of secondary action is shown by the common technical process of electropolishing with silver from a bath of potassium silver cyanide. Here the ions are potassium and the group Ag(CN)₂⁻. Each potassium ion as it reaches the cathode precipitates silver by reacting with the solution in accordance with the chemical equation

$$ K^+ + Ag(CN)_2^- \rightarrow K^+ + Ag + 2CN^- $$

while the anion Ag(CN)₂⁻ dissolves an atom of silver from the anode, and re-forms the complex cyanide KAg(CN)₂ by combining with the hydrogen ion. The amount of silver lost is described in the chemical equation. If the anode consists of platinum, cyanogen gas is evolved therefrom the anion Ag(CN)₂⁻, and the platinum becomes covered with the insoluble silver cyanide, AgCN, which soon stops the current. The coating of silver formed by this method is coherent and homogeneous, while that deposited from a solution of silver nitrate, as the result of the primary action of the current, is crystalline and easily detached.

In the electrolysis of a concentrated solution of sodium acetate, hydrogen is evolved at the cathode and a mixture of ethane and carbon dioxide at the anode. According to H. Jahn, the processes at the anode can be represented by the equations

$$ 2CH₃COO⁻ + H₂O \rightarrow 2CH₃COOH + O₂ $$

$$ 2H⁺ + CH₃COO⁻ \rightarrow CH₃CO₂H + H₂O $$

The hydrogen at the cathode is developed by the secondary action

$$ 2Na⁺ + 2H₂O \rightarrow 2NaOH + H₂ $$

Many organic compounds can be prepared by taking advantage of secondary actions at the electrodes, such as reduction by the cathodic hydrogen, or oxidation at the anode (see Electrochemistry). It is possible to distinguish between double salts and salts of compound acids. Thus J. W. Hittorf showed that when a current was passed through a solution of sodium platinocloride, the platinum appeared at the anode. The salt must therefore be derived from the acid, chloroplatinate, Na₂PtCl₆. If a current was passed through a solution of sodium chloridochloride, PtCl₄²⁻, the ions being Na⁺ and PtCl₄²⁻, for if we were a double salt it would decompose as a mixture of sodium chloride and platinum chloride and both metals would go to the cathode.

2 Grundriss der Elektrochemie (1893), p. 293; see also F. Kauffer and C. Herbig, Ber., 1909, 42, p. 3858.
ELECTROLYSIS

Early Theories of Electrolysis.—The obvious phenomena to be explained by any theory of electrolysis are the liberation of the products of chemical decomposition at the two electrodes while the intervening liquid is unaltered. To explain these facts, Theodor Grotthus (1785-1822) in 1806 put forward an hypothesis which supposed, that the opposite chemical constituents of an electrolyte-interchanged partners all along the line between the electrodes when a current passed. Thus, if the molecule of a substance in solution is represented by AB, Grotthus considered a chain of AB molecules to exist from one electrode to the other. Under the influence of an applied electric force, he imagined that the B part of the first molecule was liberated at the anode, and that the A part thus isolated united with the B part of the second molecule, which, in its turn, passed on to its A to the B of the third molecule. In this manner, the B part of the last molecule of the chain was seized by the A of the last molecule but one and, the A part of the last molecule liberated at the surface of the cathode.

Chemical phenomena—to throw further light on this question. If two solutions containing the salts AB and CD be mixed, double decomposition is found to occur, the salts AD and CB being formed. If a certain part of the first pair of substances is transformed into an equivalent amount of the second pair. The proportions between the four salts, AD, CB, AB, and CD, which exist finally in solution, are found to be the same whether water is added to AB and CD and the pair AD and CB. To explain this result, chemists suppose that both chemical changes occur simultaneously; and that equilibrium results when the rate at which AB and CD are transformed into AD and CB is the same as the rate at which the reverse change goes on. A freedom of interchange is thus indicated between the opposite parts of the molecules of salts in solution, and it follows reasonably that with the solution of a single salt, say sodium chloride, continual interchanges go on between the sodium and chlorine parts of the different molecules; and that equilibrium is reached when the rates of the two changes become equal.

These views were applied to the theory of electrolysis by R. J. E. Clausius. He pointed out that it followed that the electric forces did not cause the interchanges between the opposite parts of the dissolved molecules but only controlled their direction. Interchanges must be supposed to go on whether a current passes or not; the function of the electric forces in electrolysis being merely to determine in what direction the parts of the molecules shall work their way through the liquid and to effect actual separation of these parts (or their secondary products) at the electrodes. This conclusion is supported also by the evidence supplied by the phenomena of electrolytic conduction (see CONDUCTION, ELECTRICITY, § II.). If we eliminate the reverse electromotive forces of polarization at the two electrodes, the conduction of electricity through electrolytes is found to conform to Ohm's law; that is, once the polarization is overcome, the current is proportional to the electromotive force applied to the bulk of the liquid. Hence there can be no reverse forces of polarization inside the liquid itself, such forces being confined to the surfaces of the electrodes. No work is done in separating the parts of the molecules from each other. This result again indicates that the parts-of the molecules are effectively separate from each other, the function of the electric forces being merely directive.

Migration of the Ions.—The opposite parts of an electrolyte, which work their way through the liquid under the action of the electric forces, were named by Faraday the ions—the travellers. The changes of concentration which occur in the solution near the two electrodes were referred by W. Hittorf (1855) to the unequal speeds with which he supposed the two opposite ions to travel. It is clear that, when two opposite streams of ions move past each other, equivalent quantities are liberated at the two ends of the system. If the ions move at equal rates, the salt we begin with the pair of AB and CD liberated must be taken equally from the neighbourhood of the two electrodes. But if one ion, say the anion, travels faster through the liquid than the other, the end of the solution from which it comes will be more exhausted of salt than the end towards which it goes.

If we assume that no other cause is at work, it is easy to prove that, with non-dissolvable electrodes, the ratio of salt lost at the anode to salt lost at the cathode must be equal to the ratio of the velocity of the cation to the velocity of the anion. This result may be illustrated by fig. 2. The black circles represent the one ion and the white circles the other. If the black ions move twice as fast as the white ones, the state of things after the passage of a certain time will be represented by the lower part of the figure. Here the middle part of the solution is unaltered and the number of ions liberated is the same at either end, but the amount of salt left at one end is less than that at the other. On the right, towards which the faster ion travels, five molecules of salt are left, being a loss of two from the original seven. On the left, towards which the slower ion moves, only three molecules remain—a loss of four. Thus, the ratio of the losses at the two ends is two to one—the same as the ratio of the assumed ionic velocities. It should be noted, however, that another cause would be competent to explain the unequal dilution of the two solutions. If either ion carried with it some of the unaltered salt or some of the solvent, concentration or dilution of the liquid would be produced where the ion was liberated. There is reason to believe that in certain cases such complex ions do exist, and interfere with the results of the dilution ionic velocities.

Hittorf and many other observers have made experiments to determine the unequal dilution of a solution round the two electrodes when a current passed. Various forms of apparatus have been used, the principle of them all being to secure efficient separation of the two volumes of solution in which the changes occur. In some cases porous diaphragms have been employed; but such diaphragms introduce a new complication, for the liquid past the diaphragm is pushed through the solution of the second compartment by the phenomenon being known as electric endosmosis. Hence experiments without separating diaphragms are to be preferred, and the apparatus may be considered effective when a considerate bulk of intervening solution is left unaltered in composition. It is usual to express the results in terms of what is called the migration constant of the union; that is, the ratio of the amount of salt lost by the anode vessel to the whole amount lost by both vessels. Thus the statement that the migration constant or transport number for a decinormal solution of copper sulphate is 0.532 implies that of every gramme of copper sulphate lost by a solution containing originally one-tenth of a gramme equivalent per litre when a current is passed through it between platinum electrodes, 0.532 grammes are taken from the cathode vessel and 0.468 gramme from the anode vessel. For certain concentrated solutions the transport number is found to be greater than unity; thus for a normal solution of caesium iodide its value is 1.29. On the theory that the phenomena are wholly due to unequal ionic velocities this result would mean that the cation like the anion moved against the conventional direction of the current. That a body carrying a positive electric charge should move against the direction of the electric intensity is contrary to all our notions of electric forces, and we are compelled to seek some other explanation. An alternative hypothesis is given by the idea of complex ions. If some of the unions, instead of being simple 2ions, are represented chemically by the symbol II, are complex substances formed by the union of iodine with unaltered caesium iodide—structures represented by some such chemical formula as \( \text{Ca}^{+} \text{II}\). If the concentration of the solution round the anode would be increased by the passage of an electric current, and the phenomena observed would be explained. It is found that, in such cases as this, where it seems necessary to imagine the existence of complex ions, the transport number changes rapidly as the concentration of the original solution is changed. Thus, diminishing the concentration of the caesium iodide solution from normal to one-twentieth normal changes the transport number from 1.29 to 0.04. Hence it is probable that in cases where the transport number keeps constant...
ELECTROLYSIS

changing concentration the hypothesis of complex ions is unnecessary, and we may suppose that the transport number is a true migration constant from which the relative velocities of the two ions may be calculated in the matter suggested by Hittorf and illustrated in fig. 2. This conclusion is confirmed by the results of the direct visual determination of ionic velocities (see CONDUCTION, ELECTRIC, § II.), which, in cases where the transport number remains constant, agree with the values calculated from those numbers. Many solutions in which the transport numbers vary at high concentration often become simple at greater dilution. For instance, to take the two solutions to which we have already referred, we have—

<table>

</table>

It is probable that in both these solutions complex ions exist at fairly high concentrations, but gradually lose less in number and finally disappear as the dilution is increased. In such salts as potassium chloride the ions seem to be simple throughout a wide range of concentration since the transport numbers for the same series of concentrations as those used above run—

The next important step in the theory of the subject was made by F. Kohlrausch in 1879. Kohlrausch formulated a theory of electrolytic conduction based on the idea that, under the action of the electric forces, the oppositely charged ions moved in opposite directions through the liquid, carrying their charges with them. If we eliminate the polarization at the electrodes, it can be shown that an electrolyte possesses a definite electric resistance and therefore a definite conductivity. The conductivity gives us the amount of electricity conveyed per second under a definite electromotive force. On the view of the process of conduction described above, the amount of electricity conveyed per second is measured by the product of the number of ions, known from the concentration of the solution, the charge carried by each of them, and the velocity with which, on the average, they move through the liquid. The concentration is known, and the conductivity can be measured experimentally; thus the average velocity with which the ions move past each other under the existent electromotive force can be estimated. The velocity with which the ions move past each other is equal to the sum of their individual velocities, which can therefore be calculated. Now Hittorf's transport number, in the case of simple salts in moderately dilute solution, gives us the ratio between the two ionic velocities. Hence the absolute velocities of the two ions can be determined, and we can calculate the actual speed with which a certain ion moves through a given liquid under the action of a given potential gradient or electromotive force. The details of the calculation are given in the article CONDUCTION, ELECTRIC, § II., where also will be found an account of the methods which have been used to measure the velocities of many ions by direct visual observation. The results go to show that, where the existence of complex ions is not indicated by varying transport numbers, the observed velocities agree with those calculated on Kohlrausch's theory.

Dissociation Theory.—The verification of Kohlrausch's theory of ionic velocity verifies also the view of electrolysis which regards the electric current as due to streams of ions moving in opposite directions through the liquid and carrying their opposite electric charges with them. There remains the question how the necessary migratory freedom of the ions is secured. As we have seen, Grotthus imagined that it was the electric forces which sheared the ions past each other and loosened the chemical bonds holding the opposite parts of each dissolved molecule together. Clausius extended to electrolysis the chemical ideas which looked on the opposite parts of the molecule as always changing partners independently of any electric force, and regarded the function of the current as merely directive. Still, the necessary freedom was supposed to be secured by interchanges

which the solvent can pass but the solvent cannot, the solvent will enter till a certain equilibrium pressure is reached. This equilibrium pressure is called the osmotic pressure of the solution, and thermodynamic theory shows that, in an ideal case of perfect separation between solvent and solute, it should have the same value as the pressure which a number of molecules equal to the number of solute molecules in the solution exert if they could exist as a gas in a space equal to the volume of the solution, provided that the space was large enough (i.e. the solution dilute enough) for the intermolecular forces between the dissolved particles to be inappreciable. Van 't Hoff pointed out that measurements of osmotic pressure confirmed this value in the case of dilute solutions of cane sugar.

Thermodynamic theory also indicates a connexion between the osmotic pressure of a solution and the depression of its freezing point and its vapour pressure compared with those of the pure solvent. The freezing points and vapour pressures of solutions of sugar are also in conformity with the theoretical numbers. But when we pass to solutions of mineral salts and acids—to solutions of electrolytes in fact—we find that the observed values of the osmotic pressures and of the allied phenomena are greater than the normal values. Arrehnius pointed out that these exceptions would be brought into line if the ions of electrolytes were imagined to be separate entities each capable of producing its own pressure effects just as would an ordinary dissolved molecule.

Two relations are suggested by Arrehnius' theory. (1) In very dilute solutions of simple substances, where only one kind of dissociation is possible and the dissociation of the ions is complete, the number of pressure-producing particles necessary to produce the observed osmotic effects should be equal to the number of ions given by a molecule of the salt as showing any of its electrical properties. Thus the osmotic pressure, or the depression of the freezing point of a solution of potassium chloride should, at extreme dilution, be twice the normal value, but of a solution of sulphuric acid three times that value, since the potassium salt contains two ions and the acid three. (2) As the concentration of the solutions increases, the ionization as measured electrolytically and the dissociation as measured osmotically might decrease more or less together, though, since the thermodynamic theory only holds when the solution is so dilute that the dissolved particles are beyond each other's sphere of action, there is much doubt whether this second relation is valid through any appreciable range of concentration.

At present, measurements of freezing point are more convenient and accurate than those of osmotic pressure, and we may test the validity of Arrehnius' relations by their means. The theoretical value for the depression of the freezing point of a dilute solution per gramme-equivalent of solute per litre is 1.857° C. Completely ionized solutions of salts with two ions should give double this number or 3.714°, while electrolytes with three ions should have a value of 5.57°.

The following results are given by H. B. Loomis for the concentration of 0.01 gramme-molecule of salt to one thousand grammes of water. The salts tabulated are those of which the
electrolysis

§ II. "Nature of Electrolytes"). It is probable that the electrical effects constitute the strongest arguments in favour of the theory. It is necessary to point out that the dissociated ions of such a body as potassium chloride are not in the same condition as potassium and chlorine in the free state. The ions are associated with very large electric charges, and, whatever their exact relations with those charges may be, it is certain that the energy of a system in such a state must be different from its energy when uncharged. It is not unlikely, therefore, that even a compound as simple as the solid form of potassium chloride should be thus dissociated when dissolved. Again, water, the best electrolytic solvent known, is also the body of the highest specific inductive capacity (dielectric constant), and this property, to whatever cause it may be due, will reduce the forces between electric charges in the neighbourhood, and may therefore enable two ions to separate.

This view of the nature of electrolytic solutions at once explains many well-known phenomena. Other physical properties of these solutions, such as density, colour, optical rotatory power, and, like the conductivities, are additive, i.e. can be calculated by adding together the corresponding properties of the parts. This again suggests that these parts are independent of each other. For instance, the colour of a salt solution is the colour obtained by the superposition of the colours of the ions and the colour of any undissociated salt that may be present. All copper salts in water solution are blue, which is therefore the colour of the copper ion. Solid copper chloride is brown or yellow, so that its concentrated solution, which contains both ions and undissociated molecules, is green, but changes to blue as water is added and the ionization becomes complete. A series of equivalent solutions all containing the same coloured ion have absorption spectra which, when photographed, show identical absorption bands of equal intensity. The colour changes shown by many substances which are used as indicators (pH) of acids or alkalies can be explained in a similar way. Thus para-nitrophenol has colourless molecules, but an intensely yellow negative ion. In neutral, and still more in acid solutions, the dissociation of the indicator is practically nothing, and the liquid is colourless. If an alkali is added, however, a highly dissociated salt of para-nitrophenol is formed, and the yellow colour is at once evident. In other cases, such as that of litmus, both the ion and the undissociated molecule are coloured, but in different ways.

Electrolytes possess the power of coagulating solutions of colloids such as albumen and arsenic sulphide. The mean values of the relative coagulative powers of sulphates of monovalent, divalent, and tri-valent metals have been shown experimentally to be approximately in the ratios 1:3.5:10.3. The dissociation theory refers this to the action of electric charges carried by the free ions. If a certain minimum charge must be collected in order to start coagulation, it will need the conjunction of 6 ions monovalent, or 3 ions divalent, to equal the effect of 2 tri-valent ions. The ratios of the coagulative powers can thus be calculated to be 1:2:3, and putting x=2 we get 1:3:2:10,4, a satisfactory agreement with the numbers observed.

The question of the application of the dissociation theory to the case of fused salts remains. While it seems clear that the conduction in this case is carried on by ions similar to those of solutions, since Faraday's laws apply equally to both, it does not follow necessarily that semi-permanent dissociation is the only way to explain the phenomena. The evidence in favour of dissociation in the case of solutions does not apply to fused salts, and it is possible that, in their case, a series of molecular interchanges, somewhat like Grothuss's chain, may represent the mechanism of conduction.

An interesting relation appears when the electrolytic conductivity of solutions is compared with their chemical activity. The readiness and speed with which electrolytes react in

sharp contrast with the difficulty experienced in the case of non-electrolytes. Moreover, a study of the chemical relations of electrolytes indicates that it is always the electrolytic ions that are concerned in their reactions. The tests for a salt, potassium nitrate, for example, are the tests not for KNO₃, but for its ions K and NO₃, and in cases of double decomposition it is the ions, and not the original substances, that are exchanged for others.

If an element be present in a compound otherwise than as an ion, it is not interchangeable, and cannot be recognized by the usual tests. Thus neither a chloride, which contains the ion Cl⁻, nor monochloracetic acid, shows the reactions of chlorine, though it is, of course, present in both substances: again, the sulphates do not answer to the usual tests which indicate the presence of sulphur as sulphide. The chemical activity of a substance is a quantity which may be measured by different methods. For some substances it has been shown to be independent of the particular reaction used. It is then possible to assign to each body a specific coefficient of affinity. Arrhenius has pointed out that the coefficient of affinity of an electrolyte is proportional to its electrolytic ionization.

The affinities of acids have been compared in several ways. W. van 't Hoff (Z. physikal. Chem., 1888, ii. p. 278; 1890, iii. pp. 170, 241, 369). In the case of electrolytes, however, the question of the dependence of the affinity of a hydrochloric acid being taken as one hundred. Another method is to allow an acid to act on an insoluble salt, and to measure the quantity of solution taken. This is the method followed in all the following tables. The affinities of hydrochloric acid, being taken as one hundred, and of other acids the values found are shown in the following table.

It must be remembered that, the solutions not being of quite the same strength, these numbers are not strictly comparable, and that the experimental difficulties involved in the chemical measurements are considerable. Nevertheless, the remarkable general agreement of the numbers in the four columns is quite enough to show the intimate connexion between chemical activity and electrical conductivity. We may take it, then, that only that portion of these bodies is chemically active which is electrolytically active—that ionization is necessary for such chemical activity as we are dealing with here, just as it is necessary for electrolytic conductivity.

The ordinary laws of chemical equilibrium apply to the case of the dissociation of a substance into its ions. Let us suppose that we have one very active acid like hydrochloric, in which dissociation is nearly complete, another like acetic, in which it is very small. In order that the solutions of these should be isodynamic and the concentrations of the hydrogen ions the same, we must have a very large quantity of the feebly dissociated acetic acid, and a very small quantity of the strongly dissociated hydrochloric acid, and in such proportions alone will equilibrium be possible. This explains the action of a strong acid on the salt of a weak acid. Let us allow dilute sodium acetate to react with dilute hydrochloric acid. Some acetic acid is formed, and this will process will go on till the solutions of the two acids are isodynamic: that is, till the dissociated hydrogen ions are in equilibrium with both. In order for this to hold, we must have a very large quantity of the strongly dissociated hydrochloric acid, and a very small quantity of the weak acid. This is universally accepted as an accurate representation of the facts.

The temperature coefficient of conductivity has approximately the same value for most aqueous salt solutions. It increases both as the temperature increases and as the concentration is increased, ranging from about 3.5% per degree for extremely dilute solutions (i.e., practically pure water) to about 1.5% per degree for strong solutions.
for concentrated solutions at 18°. For acids its value is usually rather less than for salts at equivalent concentrations. The influence of temperature on the conductivity of solutions depends on (1) the ionization, and (2) the frictional resistance of the liquid to the passage of the ions, the reciprocal of which is called the ionic fluidity. At extreme dilution, when the ionization is complete, a variation in temperature cannot change its amount. The rise of conductivity with temperature, therefore, shows that the fluidity becomes greater as the solution is heated. As the concentration is increased and un-ionized molecules are formed, a change in temperature begins to affect the ionization as well as the fluidity. But the temperature coefficient of conductivity is now generally less than before; thus the effect of temperature on ionization must be of opposite sign to its effect on fluidity. The ionization of a solution, then, is usually diminished by raising the temperature. In conductivity being due to the greater increase in fluidity. Nevertheless, in certain cases, the temperature coefficient of conductivity becomes negative at high temperatures, a solution of phosphoric acid, for example, reaching a maximum conductivity at 75° C.

The dissociation theory gives an immediate explanation of the fact that, in general, no heat-change occurs when two neutral salt solutions are mixed. Since the salts, both before and after mixture, exist mainly as dissociated ions, it is obvious that large thermal effects can only appear when the state of dissociation of the products is very different from that of the reagents. Let us consider the case of the neutralization of a base by an acid in the light of the dissociation theory. In dilute solution such substances as hydrochloric acid and potash are almost completely dissociated, so that, instead of representing the reaction as:

\[ \text{HCl} + \text{KOH} = \text{KCl} + \text{H}_2\text{O}. \]

we must write:

\[ +\text{H}^+ + \text{Cl}^- + \text{K}^+ + \text{OH}^- = \text{K}^+ + \text{Cl}^- + \text{H}_2\text{O}. \]

The ions K and Cl suffer no change, but the hydrogen of the acid and the hydroxyl (OH) of the potash unite to form water, which is only very slightly dissociated. The heat liberated, then, is almost exclusively that produced by the formation of water from its ions. An exactly similar process occurs when any strongly dissociated acid acts on any strongly dissociated base, so that in all such cases the heat evolution should be approximately the same. This is fully borne out by the experiments of Julius Thomsen, who found that the heat of neutralization of one gramme-molecule of a strong base by an equivalent quantity of a strong acid was nearly constant, and equal to 13,700 or 13,800 calories. In the case of weaker acids, the dissociation of which is less complete, divergences from this constant value will occur, for some of the molecules have to be separated into their ions. For instance, sulphuric acid, which in the fairly strong solutions used by Thomsen is only about half dissociated, at the temperature of the solutions, gives a heat value for the heat of neutralization, so that heat must be evolved when it is ionized. The heat of formation of a substance from its ions is, of course, very different from that evolved when it is formed from its elements in the usual way, since the energy associated with an ion is different from that possessed by the atoms of the element in their normal state. We can calculate the heat of formation from its ions for any substance dissolved in a given solvent, from a knowledge of the temperature coefficient of ionization, by means of an application of the well-known thermodynamical process, which also gives the latent heat of vaporization of a liquid when the temperature coefficient of its vapour pressure is known. The heats of formation thus obtained may be either positive or negative, and by using them to supplement the heat of formation of water, Arrhenius calculated the total heats of neutralization of soda by different acids, some of them being obtained together with the latent heats of vaporization, and found values agreeing well with observation (Zeits. physikal. Chemie, 1884, 9, p. 166; and 1892, 9, p. 339).

Voltaic Cells.—When two metallic conductors are placed in an electrolyte, a current will flow through a wire connecting them provided that a difference of any kind exists between the two conductors in the nature either of the metals or of the portions of the electrolyte which surround them. A current can be obtained by the combination of two metals in the same electrolyte, of two metals in different electrolytes, of the same metal in different electrolytes, or of the same metal in solutions of the same electrolyte at different concentrations. In accordance with the principles of energetics (q.e.), any change which involves a decrease in the total available energy of the system will tend to occur, and thus the necessary and sufficient condition for the production of a current is that the total available energy of the system should decrease when the current flows.

In order that the current should be maintained, and the electromotive force of the cell remain constant during action, it is necessary to ensure that the changes in the cell, chemical or other, which produce the current, should neither destroy the difference between the electrodes, nor coat either electrode with a non-conducting layer through which the current cannot pass. As an example of a fairly constant cell we may take that of Daniell, which consists of the electrical arrangement—zinc \| zinc sulphate solution \| copper sulphate solution \| copper,—the two solutions being usually separated by a pot of porous earthenware. When the zinc and copper plates are connected through a wire, a current flows, the conventionally positive electricity passing from copper to zinc in the wire and from zinc to copper in the cell. Zinc dissolves at the anode, an equal amount of copper being deposited on the cathode. The state of affairs at the cathode is that the porous partition, and the same amount of copper is deposited on the cathode. This process involves a decrease in the available energy of the system, for the dissolution of zinc gives out more energy than the separation of copper absorbs. But the internal rearrangements which accompany the production of a current do not cause any change in the original nature of the electrodes, fresh zinc being exposed at the anode, and copper being deposited on copper at the cathode. Thus as long as a moderate current flows, the only variation in the cell is the appearance of zinc sulphate in the liquid on the copper side of the porous wall. In spite of this appearance, however, while the supply of copper is maintained, copper, being more easily separated from the solution than zinc, is deposited alone at the cathode, and the cell remains constant.

It is necessary to observe that the condition for change in a system is that the total available energy of the whole system should be decreased by the change. We must consider what change is allowed by the mechanism of the system, and deal with the sum of all the alterations in energy. Thus in the Daniell cell the dissolution of copper as well as of zinc would increase the loss in available energy. But when zinc dissolves, the zinc ions carry their electric charges with them, and the liquid tends to become positively electrified. The electric forces then stop further action unless an equivalent quantity of positive ions are removed from the solution. Hence zinc can only continue to dissolve when some more easily separable substance is present in solution to be removed pari passu with the dissolution of zinc. The mechanism of such systems is well illustrated by an experiment devised by W. Ostwald. Plates of platinum and pure or amalgamated zinc are separated by a porous pot, and each surrounded by some of the same solution of a salt of a metal more oxidizable than zinc, such as potassium. When the plates are connected together, a current is set up which can be no appreciable amount of zinc dissolves, for the dissolution of zinc would involve the separation of potassium and a gain in available energy. If sulphuric acid be added to the vessel containing the zinc, these conditions are unaltered and still no zinc is dissolved. But, on the other hand, if a few drops of acid be placed in the vessel with the platinum, bubbles of hydrogen appear, and a current flows, zinc dissolving at the anode, and hydrogen being liberated at the cathode. In order that positively electrified ions may enter a solution, an equivalent amount of other positive ions must be removed or negative ions be added, and, for the process to occur spontaneously, the possible action at the two electrodes must involve a decrease in the total available energy of the system.

Considered thermodynamically, voltaic cells must be divided
ELECTROLYSIS

into reversible and non-reversible systems. If the slow processes of diffusion be ignored, the Daniell cell already described may be taken as a type of a reversible cell. Let an electromotive force exactly equal to that of the cell be applied to it in the reverse direction. When the applied electromotive force is diminished by an infinitesimal amount, the cell produces a current in the usual direction, and the ordinary chemical changes occur. Now, if the reverse electromotive force be taken that of the cell by ever so little, a current flows in the opposite direction, and all the former chemical changes are reversed, copper dissolving from the copper plate, while zinc is deposited on the zinc plate. The cell, together with this balancing electromotive force, is thus a reversible system in true equilibrium, and the thermodynamical reasoning applicable to such systems can be used to examine its properties.

The well-known relation connects the available energy of a reversible system with the corresponding change in its total internal energy.

The available energy \( A \) is the amount of external work obtainable by an infinitesimal, reversible change in the system which occurs at a constant temperature \( T \). If \( I \) be the change in the internal energy, the relation referred to gives us the equation

\[
A = I + T \frac{dA}{dT}
\]

where \( dA/dT \) denotes the rate of change of the available energy of the system per degree change in temperature. During a small external work done on the cell, the external work done is \( -E \), where \( E \) is the electromotive force. If the chemical changes which occur in the cell were allowed to take place in a closed vessel without the performance of external mechanical work, the vessel would not be heated by the heat evolved. Since the final state of the system would be the same as in the actual processes of the cell, the same amount of heat must give a measure of the change in internal energy when the cell is in action. Thus, if \( L \) denote the heat corresponding with the chemical changes associated with unit electric transfer \( L \) will be the heat corresponding with an electric transfer \( e \), and will also be equal to the change in internal energy of the cell. Hence we get the equation

\[
E = T \frac{dA}{dT} + L \frac{dI}{dT} = E - T \frac{dA}{dT}
\]

as a particular case of the general thermodynamic equation of available energy. This equation was obtained in different ways by J. W. Gibbs and H. von Helmholtz.

It will be noticed that when \( dE/dT \) is zero, that is, when the electromotive force of the cell does not change with temperature, the electromotive force is measured by the heat of reaction per unit of electrochemical change. The earliest formulation of the subject, due to Lord Kelvin, assumed that this relation was true in all cases, and, calculated in this way, the electromotive force of Daniel's cell, which possesses for a very small temperature coefficient, was found to agree with observation.

When one gramme of zinc is dissolved in dilute sulphuric acid, 1600 electrons or charges are expelled. Hence for the electrochemical unit of zinc or 0.003388 gramme, the thermal evolution is 5.66 calories. Similarly, the heat which accompanies the dissolution of one electrochemical unit of copper is 5.00 calories. Thus, the thermal evolution of the unit of result of the electrochemical change in Daniel's cell is 5.66-5.00=0.66 calories. The dynamical equivalent of the calorie is 4.18x10^7 ergs or C.G.S. units of work, and therefore the electromotive force of the cell should be 1.122 x 10^7 C.G.S. units or 1.122 volts—a close agreement with the experimental result of about 1.08 volts. For cells in which the electromotive force varies with temperature, the full equation given by Gibbs and Helmholtz has also been confirmed experimentally.

As stated above, an electromotive force is set up whenever there is a difference of any kind at two electrodes immersed in electrolytes. In ordinary cells the difference is secured by using two dissimilar metals, but an electromotive force exists if two plates of the same metal are placed in solutions of different substances, or of the same substance at different concentrations. In the latter case, the tendency of the metal to dissolve in the more dilute solution is greater than its tendency to dissolve in the more concentrated solution, and work there is a decrease in available energy when metal dissolves in the dilute solution and separates in equivalent quantity from the concentrated solution. An electromotive force is therefore set up in this direction, and, if we can calculate the change in available energy due to the processes of the cell, we can get the electromotive force. Now the effective change produced by the action of the current is the concentration of the more dilute solution by the dissolution of metal in it, and the dilution of the originally stronger solution by the separation of metal from it. We may imagine these changes reversed in two ways. We may evaporate some of the solvent from the solution which has become weaker and thus reconcentrate it, condensing the vapour on the solution which had become stronger. By this reasoning Helmholtz showed how to obtain an expression for the work done. On the other hand, we may imagine the process due to the chemical transfer to be reversed by an osmotic operation. Solvent may be supposed to be squeezed out from the solution which has become more dilute through a semi-permeable wall, and through another such wall allowed to mix with the solution which in the electrical operation had become more concentrated. Again, we may calculate the osmotic work done, and, if the whole cycle of operations be supposed to occur at the same temperature, the osmotic work must be equal and opposite to the electrical work of the first operation.

The result of the investigation shows that the electrical work \( E \) is given by the equation

\[
E = \int p \, dp,
\]

where \( p \) is the volume of the solution used and \( q \) its osmotic pressure. When the solutions may be taken as effectively dilute, so that the gas laws apply to the osmotic pressure, this relation reduces to

\[
E = \frac{RT}{\rho q} \ln \frac{a}{aq}
\]

where \( a \) is the number of ions given by one molecule of the salt, \( r \) the transport ratio of the anion, \( R \) the gas constant, \( T \) the absolute temperature, \( \gamma \) the total valency of the anions obtained from one molecule, and \( a \) and \( q \) the change in the osmotic pressure of the solvent. If we take as an example a concentration cell in which silver plates are placed in solutions of silver nitrate, one of which is ten times as strong as the other, this equation gives

\[
E = 0.060 \times 10^7 \text{C.G.S. units}
\]

or 0.5 volt.

W. Nernst, to whom this theory is due, determined the electromotive force of this cell experimentally, and found the value 0.055 volt.

The logarithmic formulae for these concentration cells indicate that theoretically their electromotive force can be increased to any extent by diminishing without limit the concentration of the more dilute solution, log \( a/\gamma a \) then becoming very great. This condition may be realized to some extent in a manner that throws light on the general theory of the voltaic cell. Let us consider the arrangement—silver | silver chloride with potassium chloride solution | potassium nitrate solution | silver nitrate solution | silver. Silver chloride is a very insoluble substance, and here the amount in solution is still further reduced by the presence of excess of chlorine ions of the potassium salt. Thus silver, at one end of the cell in contact with many silver ions of the silver nitrate solution, at the other end is in contact with a molecule, which the concentration of those ions is very small indeed. The result is that a high electromotive force is set up, which has been calculated as 0.52 volt, and observed as 0.51 volt. Again, Hittorf has shown that the effect of a cyanide round a copper electrode is to combine with the copper ions. The concentration of the simple copper ions is then so much diminished that the copper plate becomes an anode with regard to zinc. Thus the cell—copper | potassium cyanide solution | potassium sulphate solution—zinc sulphate solution | zinc—gives a current which carries copper into solution and deposits zinc. In a similar way silver could be made to act as anode with respect to cadmium.

It is now evident that the electromotive force of an ordinary chemical cell such as that of Daniell depends on the concentration of the solutions as well as on the nature of the metals. In ordinary cases possible changes in the concentrations only affect the electromotive force by a few parts in a hundred, but, by much larger changes, as those indicated above, it is possible to produce such immense differences in the concentrations that the electromotive force of the cell is not only changed appreciably but even reversed in direction. Once more we see that it is the total impending change in the available energy of the system which controls the electromotive force.

Any reversible cell can theoretically be employed as an accumulator, though, in practice, conditions of general convenience are more sought after than thermodynamic efficiency.
The effective electromotive force of the common lead accumulator (g.p.) is less than that required to charge it. This drop in the electromotive force has led to the belief that the cell is not reversible. F. Dolezalek, however, has attributed the difference to mechanical hindrances, which prevent the equalization of acid concentration in the neighbourhood of the electrodes, rather than to any essentially irreversible chemical action. The fact that the Gibbs-Helmholtz equation is found to apply also indicates that the lead accumulator is approximately reversible in the usual sense of the term.

**Polarization and Contact Difference of Potential.**—If we connect together in series a single Daniell's cell, a galvanometer, and two platinum electrodes dipping into acidulated water, no visible chemical decomposition ensues. At first a considerable current is indicated by the galvanometer; the deflexion soon diminishes, however, and finally becomes very small. If, instead of using a single Daniell's cell, we employ some source of electromotive force which can be varied as we please, and gradually raise its intensity, we shall find that, when it exceeds a certain value, about 1.7 volt, a permanent current of considerable strength flows through the solution, and, after the initial period, shows no signs of decrease. This current is accompanied by chemical decomposition. Now let us disconnect the platinum plates from the battery and join them directly with the galvanometer. A current will flow for a while in the reverse direction; the system of plates and acidulated water through which a current has been passing is thus charged as a accumulator. Differences between the two electrodes are thus set up, and, as we have seen above, an electromotive force will therefore exist between them. To pass a steady current in the direction opposite to this electromotive force of polarization, the applied electromotive force E must exceed that of polarization E', and the excess E - E' is the effective electromotive force of the circuit, the current being, in accordance with Ohm's law, proportional to the applied electromotive force and represented by (E - E')/R, where R is a constant called the resistance of the circuit.

When we use platinum electrodes in acidulated water, hydrogen and oxygen are evolved. The opposing force of polarization is about 1.7 volt, but, when the plates are disconnected and used as a source of current, the electromotive force they give is only about 1.0 volt. This irreversibility is due to the work required to evolve bubbles of gas at the surface of bright platinum plates. If the plates be covered with a deposit of platinum black, in which the gases are absorbed as fast as they are produced, the minimum decomposition point is 1.0 volt, and the process is reversible. If secondary effects are eliminated, the deposition of metals also is a reversible process; the decomposition voltage is equal to the electromotive force which the metal itself gives when going into solution. The phenomena of polarization are thus seen to be due to the changes of surface produced, and are correlated with the differences of potential which exist at any surface of separation between a metal and an electrolyte.

Many experiments have been made with a view of separating the two potential-differences which must exist in any cell made of two metals and a liquid, and of determining each one individually. If we regard the thermal effect at each junction as a measure of the potential-difference there, as the total thermal effect in the cell undoubtedly is of the sum of its potential-differences, in cases where the temperature coefficient is negligible, the best evolved conclusion of a metal should give the electrical potential-difference at its surface. Hence, if we assume that, in the Daniell's cell, the temperature coefficients are negligible at the individual contacts as well as in the cell as a whole, the sign of the potential-difference ought to be the same at the surface of the zinc as it is at the surface of the copper. Since zinc goes into solution and copper comes out, the electromotive force of the cell will be the difference between the two effects. On the other hand, it is commonly thought that the single potential-differences at the surface of metals and electrolytes have been determined by methods based on the use of the capillary electrometer and on others depending on what is called a dropping electrode, that is, mercury dropping rapidly into an electrolyte and forming a cell with the mercury at rest in the bottom of the vessel. By both these methods the single potential-differences found at the surfaces of the zinc and copper have opposite signs, and the effective electromotive force of a Daniell's cell is the sum of the two effects. Which of these conflicting views represents the truth still remains uncertain.

**Diffusion of Electrolytes and Contact Difference of Potential between Liquids.**—An application of the theory of ionic velocity due to W. Nernst and M. Planck enables us to calculate the diffusion constant of dissolved electrolytes. According to the molecular theory, diffusion is due to the motion of the molecules of the dissolved substance through the liquid. When the dissolved molecules are uniformly distributed, the osmotic pressure will be the same everywhere throughout the solution, but, if the concentration vary from point to point, the pressure will vary also. There must, then, be a relation between the rate of change of the concentration and the osmotic pressure gradient, and thus we may consider the osmotic pressure gradient as a force driving the solutes through a concentration gradient. By the diffusion of electrolytes and of all non-ionized molecules this analogy completely represents the facts, and the phenomena of diffusion can be deduced from it alone. But the ions of an electrolytic solution can move independently through the liquid, even when no current flows, as the consequences of Ohm's law indicate. The ions will therefore diffuse independently, and the faster ion will travel quicker into pure water in contact with a solution. The ions carry with them, as a matter of fact, it is found that water in contact with a solution takes with respect to it a positive or negative potential, according as the positive or negative ion travels the faster. This process will go on until the simultaneous separation of electric charges produces an electrostatic force strong enough to prevent further separation of ions. We can therefore calculate the rate at which the salt as a whole will diffuse by examining the conditions for a steady transfer, in which the ions diffuse, and, as an equal rate, the faster one being restrained and the slower one urged forward by the electric forces. In this manner the diffusion constant can be calculated in absolute units (HCl=2.49, HNO₃=2.27, NaCl=1.12), the unit of time being the day. By experiments on diffusion this constant has been found by Scheffer, and the numbers observed agree with those calculated (HCl=2.30, HNO₃=2.22, NaCl=1.11).

As we have seen above, when a solution is placed in contact with water the water will take a positive or negative potential with regard to the solution, according as the cation or anion has the greater specific velocity, and therefore the greater initial rate of diffusion. The difference of potential between two solutions of a substance at different concentrations can be calculated from the equations used to give the diffusion constants. The results give equations of the same logarithmic form as those obtained in a somewhat different manner in the theory of concentration cells described above, and have been verified by experiment.

The contact differences of potential at the interfaces of metals and electrolytes have been co-ordinated by Nernst with those at the surfaces of separation between different liquids. In contact with a solvent a metal is supposed to possess a definite solution pressure, analogous to the vapour pressure of a liquid. Metal goes into solution in the form of electrified ions. The liquid thus acquires a positive charge, and the metal a negative charge. The electric forces set up tend to prevent the separation, and finally a state of equilibrium is reached, when no

1 Zeits. physikal. Chem. 2, p. 613.
more ions can go into solution unless an equivalent number are removed by voltaic action. On the analogy between this case and that of the interface between two solutions, Nernst has arrived at similar logarithmic expressions for the difference of potential, which becomes proportional to \( \log \left( \frac{P_i}{P_0} \right) \) where \( P_i \) is taken to mean the osmotic pressure of the cations in the solution, and \( P_0 \) the osmotic pressure of the cations in the substance of the metal itself. On these lines the equations of concentration cells, deduced above on less hypothetical grounds, may be regained.

**Theory of Electrons.**—Our views of the nature of the ions of electrolytes have been extended by the application of the ideas of the relations between matter and electricity obtained by the study of electric conduction through gases. The interpretation of the phenomena of gaseous conduction was rendered possible by the knowledge previously acquired of conduction through liquids; the newer subject is now reaching a position whence it can repay its debt to the older.

Sir J. J. Thomson has shown (see **Conduction, Electric, § III.**) that the negative ions in certain cases of gaseous conduction are much more mobile than the corresponding positive ions, and possess a mass of about the one-thousandth part of that of a hydrogen atom. These negative particles or corpuscles seem to be the ultimate units of negative electricity, and may be identified with the electrons required by the theories of H. A. Lorentz and Sir J. Larmor. A body containing an excess of these particles is said to be electrified, and the resistance of the body is a function of the number of electrons it has parted with of its normal number. An electric current consists of a moving stream of electrons. In gases the electrons sometimes travel alone, but in liquids they are always attached to matter, and their motion involves the movement of chemical atoms or groups of atoms. An atom with an extra corpuscle is a univalent negative ion, an atom with one corpuscle detached is a univalent positive ion. In metals the electrons can slip from one atom to the next, since a current can pass without chemical action. When a current passes from an electrolyte to a metal, the electron must be detached from the atom it was accompanying and chemical action be manifested at the electrode.

**ELECTROMAGNETISM,** that branch of physical science which is concerned with the interconnexion of electricity and magnetism, and with the production of magnetism by means of electric currents by devices called electromagnets.

**History.**—The foundation was laid by the observation first made by Hans Christian Oersted (1777-1851), professor of natural philosophy in Copenhagen, who discovered in 1820 that a wire uniting the poles or terminal plates of a voltaic pile has the property of affecting a magnetic needle (see **Electricity**).

1 In the *Annals of Philosophy* for November 1821 is a long article entitled "On Electromagnetism" by Oersted, in which he gives a description of his discovery. He had his thoughts turned to it as far back as 1813, but not until the 20th of July 1820 had he actually made his discovery. He seems to have been arranging a compass needle to observe any deflections during a storm, and placed near it a platinum wire through which a galvanic current was passed.

Oersted carefully ascertained that the nature of the wire itself did not influence the result but saw that it was due to the electric conflict, as he called it, round the wire; or in modern language, to the magnetic force or magnetic flux round the conductor. If a straight wire through which an electric current is flowing is placed above and parallel to a magnetic compass needle, it is found that if the current is flowing in the conductor in a direction from south to north, the north pole of the needle under the conductor deviates to the left hand, whereas if the conductor is placed under the needle, the north pole deviates to the right hand; if the conductor is doubled back over the needle, the effects of the two sides of the loop are added together and the deflection is increased. These results are summed up in the mnemonic rule: *Imagin yourself swimming in the conductor with the current, that is, moving in the direction of the positive electricity, with your face towards the magnetic needle; the north pole will then deviate to your left hand.* The deflection of the magnetic needle can therefore reveal the existence of an electric current in a neighbouring circuit, and this fact was soon utilized in the construction of instruments called galvanometers (q.v.).

Immediately after Oersted's discovery was announced, D. F. J. Arago and A. M. Ampère began investigations on the subject of electromagnetism. On the 18th of September 1820, Ampère read a paper before the Academy of Sciences in Paris, in which he announced that the voltaic pile itself affected a magnetic needle as did the unifying wire, and he showed that the passage of an electric current was equivalent with the presence of a magnetic needle. The current was a circulation round a circuit, and equivalent in magnetic effect to a very short magnet with axis placed at right angles to the plane of the circuit. He then propounded his brilliant hypothesis that the magnetization of iron was due to molecular electric currents. This suggested to Arago that wire wound into a helix carrying electric current should magnetize a steel needle placed in the interior. In the *Ann. Chim.* (1820, p. 82), "On the Magnetic Phenomena produced by Electricity," in which he announced his independent discovery of the same fact. With a large battery of 100 pairs of plates at the Royal Institution, he found in October 1820 that the unifying wire became strongly magnetic and that iron filings clung to it; also that steel needles placed across the wire were permanently magnetized. He placed a sheet of glass over the wire and sprinkling iron filings on it saw that they arranged themselves in straight lines at right angles to the wire. He then proved that Leyden jar discharges could produce the same effects. Ampère and Arago then seem to have experimented together and magnetized a steel needle wrapped in paper which was enclosed in a helical wire conveying a current. All these facts were rendered intelligible when it was seen that a wire when conveying an electric current becomes surrounded by a magnetic field. If the wire is a long straight one, the lines of magnetic force are circular and concentric with centres on the wire axis, and if the wire is bent into a circle the lines of magnetic force are endless loops surrounding and linked with the electric circuit. Since a magnetic pole tends to move along a line of magnetic force it was obvious that it should revolve round a wire conveying a current. To exhibit this fact involved, however, much ingenuity. It was first accomplished by Faraday in October 1821 (*Exper. Res. ii. p. 127*). Since the action is reciprocal a current free to move tends to revolve round a magnetic pole. The fact is most clearly shown by a small piece of apparatus made as follows: In a glass cylinder (see fig. 1) like a lamp chimney are fitted two troughs. Through the top one is passed the north end of a bar magnet which projects up above a little mercury lying in the cork. Through the top cork is passed one end of a wire from a
battery, and a piece of wire in the cylinder is flexibly connected to it, the lower end of this last piece just touching the mercury. When a current is passed in at the top wire and out at the bottom end of the bar magnet, the loop of wire revolves round the magnet pole. All text-books on physics contain in their chapters on electromagnetism full accounts of various forms of this experiment.

In 1825 another important step forward was taken when William Sturgeon (1783-1850) of London produced the electromagnet. It consisted of a horseshoe-shaped bar of soft iron, coated with varnish, on which was wound over with a small spiral or insulated copper wire through which a current of electricity can be passed. If the solenoid or wire were left alone, a current being passed through it would create in the interior of the solenoid a magnetic force \( H \), numerically equal to \( 4\pi/10 \) multiplied by the number of windings \( n \) on the solenoid, and by the current \( i \) in amperes divided by the mean length of the solenoid \( l \). The product \( AN \) is called the "amperes-turns" on the solenoid. The product \( Hl \) of the magnetic force \( H \) and the length \( l \) of the amperes-turns is called the "magnetomotive force" of the magnetic circuit, and from the above formula it is seen that the magnetomotive force denoted by (M.M.F.) is equal to \( 4\pi/10 l \times 10 \) nearly times the amperes-turns (A.N.) on the exciting coil solenoid. Otherwise (A.N.) = \( o \times 10 \) (M.M.F.). The magnetomotive force is generally in creating an effect called magnetic flux \( Z \) in the magnetic circuit, just as electromotive force \( E.M.F. \) produces electric current \( A \) in the electric circuit, and as by an electromotive force \( E \), the current varies as the E.M.F. and inversely as a quality of the electric circuit called its "resistance," so in the magnetic circuit the magnetomotive force varies as the magnetic circuit and inversely as the quality of the magnetic circuit called its "ductility." The great difference between the electric circuit and the magnetic circuit lies in the fact that whereas the electric resistance of a solid or liquid is independent of the current and the temperature, the magnetic resistance varies with the magnetic flux and cannot be defined except by means of a curve which shows its value for different fluxes. The magnetic definite, and the centimeter resembles the centimeter. In the magnetic circuit the cross section is called the "ductility" of the material. The relation between the reluctivity \( \rho = 1/\mu \) magnetic force \( H \), and flux density \( B \), is defined by the equation \( H = B/\mu \). From this we have \( H = Z(2/\pi) = B/\mu \). Again, since the exciting current on the circuit is equal to 0.8 times the M.M.F., we have finally \( AN = 0.8 B(2/\pi) \). This equation tells us the exciting force reckoned in amperes-turns, AN, with which the field must be produced in a total magnetic flux \( Z \) in it, the ring core having a mean perimeter \( l \) and cross section \( S \) and reluctivity \( \rho = 1/\mu \) corresponding to a flux density \( Z/S \). Hence before we can make use of the equation for practical purposes we need to possess a curve for the particular material showing us the value of the reluctivity corresponding to various values of the possible flux density. The reciprocal of \( \rho \) is usually called the "permeability" of the material. Curves showing the relation of \( l/\mu \) and \( S \) or \( B \) and \( \mu \), are called "permeability curves." For air and all other non-magnetic matters the permeability has a value of 1, and it is also the same for iron, nickel, and cobalt. On the other hand, for iron, nickel, and cobalt the permeability may in some cases reach a value of 2000 or 2500 for a value of \( B = 5000 \) in C.G.S. measure (see UNITS, PHYSICAL). The process of taking these curves for iron is a matter of precise work. To find the permeability of a solenoid of known number of turns wound on a circular iron ring of known dimensions, and observing the time-integral of the secondary current produced in a secondary circuit of known turns and resistances \( R \) wound over the iron core \( N \) times. The secondary electromotive force is by Faraday's law (see ELECTROKINETICS) equal to the time rate of change of the total flux, or \( E = N dZ/dt \). But by Ohm's law \( E = Rq \), where \( q \) is the quantity of electricity set flowing in the secondary circuit by suddenly changing the direction of the magnetic flux \( Z \) in the iron core we must have

\[
Rq = NZ = Rq/N.
\]

The measurement of the total quantity of electricity \( Q \) can be made by means of a ballistic galvanometer (p.6), and the resistance \( R \) of the secondary circuit includes that of the coil wound on the iron core and the galvanometer as well. In this manner the value of the total flux \( Z \) and therefore of \( Z/S \) or \( B \) and the flux density, can be found for a given magnetizing force \( H \), and this last quantity is determined when we know the magnetizing current in the solenoid and the length and dimensions of the current-carrying portions of \( H \) and \( B \) is called the magnetization curve for the material in question. For examples of these curves see MAGNETISM.

The fundamental law of the non-homogeneous magnetic circuit is that if one and the same magnetic field \( H \) of all the magnetomotive forces acting in the circuit is numerically equal to the product of the factor \( o \times 8 \), the total flux in the circuit, or the product of all the fluxes in the circuit. If then the circuit consists of materials of different permeability...
ELECTROMAGNETISM

and it is desired to know the ampere-turns required to produce a given total of flux round the circuit, we have to calculate from the magnetization curves of the material of each part the necessary magnetomotive forces and add these forces together. The practical application of this principle to the predetermination of the field winding of dynamo magnets was first made by J. and E. Hopkinson (Phil. Trans., 1886, 177, p. 331).

We may illustrate the principles of this predetermination by a simple ring example. A ring of iron has a mean diameter of 10 cm. and a cross section of 2 sq. cm., and a transverse cut on air gap made in it 1 mm. wide. Let us inquire the ampere-turns to be put upon the ring to create in it a total flux of 24,000 C.G.S. units. The length of the iron part of the circuit is 10 cm. (20 cm. - 10 cm.) its section is 2 sq. cm., and the flux density in it is to be 12,000. From Table II. below we see that the permeability of pure iron corresponding to a flux density of 12,000 is 2760. Hence the reluctance of the iron circuits is equal to

\[ \frac{10 \times 10^{-1} \times 0.1}{2760 \times 2} = 38640 \]

The length of the air gap is 0.1 cm., its section 2 sq. cm., and its permeability is unity. Hence the reluctance of the air gap is

\[ \frac{0.1}{2} = 0.05 \]

Accordingly the magnetomotive force in ampere-turns required to produce the required flux is equal to

\[ \frac{220 \times 0.05 + 38640}{20} = 1070 \] nearly.

It follows that the part of the magnetomotive force required to overcome the reluctance of the narrow air gap is about nine times that required for the iron alone.

In the example we have for simplicity assumed that the flux in passing across the air gap does not spread out at all. In dealing with electromagnet design in dynamo construction we have, however, to take into consideration the spreading as well as the leakage of flux across the circuit (see Dynamo). It will be seen, therefore, that in order that we may predict the effect of a certain kind of iron or steel when used as the core of an electromagnet, we must be provided with tables or curves showing the relationship or permeability corresponding to various flux densities— which comes to the same thing—with (B, H) curves for the sample of forged ingot-metal for dynamo magnets. No. IV. is a steel casting for dynamo magnets, unalloyed, made by Messrs Edgar Allen & Company by a special pneumatic process under the patents of Mr A. Tropenas. No. V. is also an unalloyed steel casting for dynamo magnets, made by Messrs Samuel Osborne & Company by the Siemens process. No. VI is also an unalloyed steel casting for dynamo magnets, made by Messrs Fried. Krupp, of Essen.

Table II. shows the magnetic qualities of some of these materials as found by Ewing when tested with small magnetizing forces.

The numbers I., III. and VI. in the above table refer to the samples mentioned in connection with Table I.

It is a remarkable fact that certain varieties of low carbon steel (commonly called mild steel) have a higher permeability than even annealed Swedish wrought iron under large magnetising forces. The term steel, however, here used has reference rather to the mode of production than to the final chemical nature of the material. In some of the mild-steel castings used for dynamo electromagnets it appears that the total foreign matter, including carbon, manganese and silicon, is not more than 0.3% of the whole, the material being 99.7% pure iron. This valuable magnetic property of steel capable of being cast is, however, of great utility in modern dynamo building, as it enables field magnets of very high permeability to be constructed, which can be fashioned into shape by casting instead of being built up as formerly out of masses of forged wrought iron. The curves in fig. 3 illustrate the manner in which the flux density or, as it is usually called, the magnetization curve of this mild cast steel crosses that of Swedish wrought iron, and enables us to obtain a higher flux density corresponding to a given magnetizing force with the steel than with the iron.

From the same paper by Ewing we extract a number of results relating to permeability tests of thin sheet iron and sheet steel, such as is used in the construction of dynamo armatures and transformer cores.

No. VII is a specimen of good transformer-plate, 0.301 millimetre thick, rolled from Swedish iron by Messrs Sankey of Bistol. No. VIII. is a specimen of specially thin transformer-plate rolled from scrap iron. No. IX is a specimen of transformer-plate rolled from scrap iron.
ingot-steel. No. X. is a specimen of the wire which was used by J. Swinburne to form the core of his "hedgehog" transformers. Its diameter was 0.62 millimetre. All these samples were tested in the form of rings by the ballistic method, the rings of sheet-metal being stamped or turned in the flat. The wire ring No. X. was coiled and annealed after coiling.

Some typical flux-density curves of iron and steel as used in dynamo and transformer building are given in fig. 4.

The numbers in Table III. well illustrate the fact that the permeability μ = B/H has a maximum value corresponding to a certain flux density. The tables are also explanatory of the fact that mild steel has gradually replaced iron in the manufacture of dynamo electromagnets and transformer-cores.

Broadly speaking, the materials which are now employed in the manufacture of the cores of electromagnets for technical purposes of various kinds may be said to fall into three classes, namely, forgings, castings and stampings. In some cases the iron or steel core which is to be magnetized is simply a mass of iron hammered or pressed into shape by hydraulic pressure; in other cases it has to be fused and cast; and for certain other purposes it must be rolled first into thin sheets, which are subsequently stamped out into the required forms.

For particular purposes it is necessary to obtain the highest possible magnetic permeability corresponding to a high, or the highest attainable flux density. This is generally the case in the electromagnets which are employed as the field magnets in dynamo machines. It may generally be said that whilst the best wrought iron, such as annealed Low Moor or Swedish iron, is more permeable for low flux densities than steel castings, the cast steel may surpass the wrought metal for high flux density. For most electro-technical purposes the best magnetic results are given by the employment of forged ingot-iron. This material is probably the most permeable throughout the whole scale of attainable flux densities. It is slightly superior to wrought iron, and it only becomes inferior to the highest class of cast steel when the flux density is pressed above 18,000 C.G.S. units (see fig. 5). For flux densities above 13,000 the forged ingot-iron has now practically replaced for electric engineering purposes the Low Moor or Swedish iron. Owing to the method of its production, it might in truth be called a soft steel with a very small percentage of combined carbon. The best description of this material is conveyed by the German term "Flusseisen," but its nearest British equivalent is "ingot-iron." Chemically speaking, the material is for all practical purposes very nearly pure iron. The same may be said of the cast steels now much employed for the production of dynamo magnet cores. The cast steel which is in demand for this purpose has a slightly lower permeability than the ingot-iron for low flux densities, but for flux densities above 16,000 the required result may be more cheaply obtained with a steel casting than with a forging. When high tensile strength is required in addition to considerable magnetic permeability, it has been found advantageous to employ a steel containing 5% of nickel. The rolled sheet iron and sheet steel which is in request for the construction of magnet cores, especially those in which the exciting current is an alternating current, are, generally speaking, produced from Swedish iron. Owing to the mechanical treatment necessary to reduce the material to a thin sheet, the permeability at low flux densities is rather higher than, although at high flux densities it is inferior
to, the same iron and steel when tested in bulk. For most purposes, however, where a laminated iron magnet core is required, the flux density is not pressed up above 6000 units, and it is then more important to secure small hysteresis loss than high permeability. The magnetic permeability of cast iron is much inferior to that of wrought or ingot iron, or the mild steels taken at the same flux densities.

The following Table IV. gives the flux density and permeability of a typical cast iron taken by J. A. Fleming by the ballistic method:-

The metal of which the tests are given in Table IV. contained 2% of silicon, 8.5% of total carbon, and 0.5% of manganese. It will be seen that a magnetizing force of about 5 C.G.S. units is sufficient to impart to a wrought-iron ring a flux density of 18,000 C.G.S. units, but the same force hardly produces more than one-tenth of this flux density in cast iron.

The testing of sheet iron and steel for magnetic hysteresis loss has developed into an important factory process, giving as it does a means of ascertaining the suitability of the metal for use in the manufacture of transformers and cores of alternating-current electromagnets.

In Table V. are given the results of hysteresis tests by Ewing on samples of commercial sheet iron and steel. The numbers VII., VIII., IX. and X. refer to the same samples as those for which permeability results are given in Table III.

For most practical purposes the constructor of electromagnetic machinery requires his iron or steel to have some one of the following characteristics. If for dynamo or magnet making, it should have the highest possible permeability at a flux density corresponding to practically maximum magnetization. If for transformer or alternating-current magnet building, it should have the smallest possible hysteresis loss at a maximum flux density of 2500 C.G.S. units during the cycle. If required for permanent magnet making, it should have the highest possible coercivity combined with a high retentivity. Manufacturers of iron and steel are now able to meet these demands in a very remarkable manner by the commercial production of material of a quality which at one time would have been considered a scientific curiosity.

It is usual to specify iron and steel for the first purpose by naming the minimum permeability it should possess corresponding to a flux density of 18,000 C.G.S. units; for the second, by stating the hysteresis loss in watts per lb per 100 cycles per second, corresponding to a maximum flux density of 2500 C.G.S. units during the cycle; and for the third, by mentioning the coercive force required to reduce to zero magnetization a sample of the material in the form of a long bar magnetized to a stated magnetization. In the cyclical reversal of magnetization of iron we have two modes to consider. In the first case, which is that of the core of the alternating transformer, the magnetic force passes through a cycle of values, the iron remaining stationary, and the direction of the magnetic force being always the same. In the other case, that of the dynamo armature core, the direction of the magnetic force in the iron is constantly changing, and at the same time undergoing a change in magnitude.

It has been shown by F. G. Bailey (Proc. Roy. Soc., 1896) that if a mass of laminated iron is rotating in a magnetic field which remains constant in direction and magnitude in any one experiment, the hysteresis loss rises to a maximum as the magnitude of the flux density in the iron is increased and then falls away again to nearly zero value. These observations have been confirmed by other observers. The question has been much debated whether the values of the hysteresis loss obtained by these two different methods are identical for magnetic cycles in which the flux density reaches the same maximum value. This question is also connected with another one, namely, whether the hysteresis loss per cycle is or is not a function of the speed with which the cycle is traversed. Early experiments by C. P. Steinmetz and others seemed to show that there was a difference between slow-speed and high-speed hysteresis cycles, but later experiments by J. Hopkinson and by A. Tanakadate, though not absolutely exhaustive, tend to prove that up to 400 cycles per second the hysteresis loss per cycle is practically unchanged.

Experiments made in 1896 by R. Beattie and R. C. Clinker on magnetic hysteresis in rotating fields were partly directed to determine whether the hysteresis loss at moderate flux densities, such as are employed in transformer work, was the same as that found by measurements made with alternating-current fields on the same iron and steel specimens (see The Electrician, 1896,
These experiments showed that over moderate ranges of induction, such as may be expected in electro-technical work, the hysteresis loss in a small per cubic centimetre was practically the same when the iron was tested in an alternating field with a periodicity of 100, the field remaining constant in direction, and when the iron was tested in a rotating field giving the same maximum flux density.

With respect to the variation of hysteresis loss in magnetic cycles having different maximum values for the flux density, Steinmetz found that the hysteresis loss (W), as measured by the area of the cycle (B, H) curve and expressed per centimetre-cube per cycle, varies proportionately to a constant called the 

**Hysteresis constant**, and to the 1.6th power of the maximum flux density (B), or \( W = C B^{1.6} \).

The hysteresetic constants (C) for various kinds of iron and steel are given in the table below:

Steinmetz’s law, though not strictly true for very low or very high maximum flux densities, is yet a convenient empirical rule for obtaining approximately the hysteresis loss at any one maximum flux density and knowing it at another, provided these values fall within a range varying say from 1 to 9000 C.G.S. units. (See Magnetism.)

The standard maximum flux density which is adopted in electro-technical work is 2500, hence in the construction of the cores of alternating-current electromagnets and transformers iron has to be employed having a known hysteresitic constant at the standard flux density. It is generally expressed by stating the number of watts per lb. of metal which would be dissipated for a frequency of 100 cycles, and a maximum flux density (B max.) during the cycle of 2500. In the case of good iron or steel for transformer-core making, it should not exceed 1-25 watt per lb. per 100 cycles per 2500 B (maximum value).

It has been found that if the sheet iron employed for cores of alternating electromagnets or transformers is heated to a temperature somewhere in the neighbourhood of 500° C. the hysteresis loss is very greatly increased. It was noticed in 1894 by G.W. Partridge that alternating-current transformers which had been in use some time had a very considerably augmented core loss when compared with their initial condition. O. T. Blath and W. M. Mordey in 1895 showed that this augmentation in hysteresis loss in iron was due to heating. H.F. Parshall investigated the effect up to moderate temperatures, such as 150° C., and an extensive series of experiments was made in 1898 by S. R. Roget (Proc. Roy. Soc., 1898, 63, p. 256, and 64, p. 150). Roget found that below 45° C. a rise in temperature did not produce any augmentation in the hysteresis loss in iron, but if it is heated to between 45° C. and 135° C. the hysteresis loss increases continuously with time, and this increase is now called “ageing” of the iron. It proceeds more slowly as the temperature is higher. If heated to above 135° C., the hysteresis loss soon attains a maximum, but then begins to decrease. Certain specimens heated to 160° C. were found to have their hysteresis loss doubled in a few days. The effect seems to come to a maximum at about 180° C. or 200° C. Mere lapse of time does not remove the increase, but if the iron is annealed the augmentation in hysteresis disappears. If the iron is heated to a higher temperature, say between 300° C. and 700° C., Roget found the initial rise of hysteresis happens more quickly, but that the metal soon settles down into a state in which the hysteresis loss has a small but still augmented constant value. The augmented value, however, becomes more nearly zero as the temperature approaches 700° C. Brands of steel are now obtainable which do not age in this manner, but these non-ageing varieties of steel have not generally such low initial hysteresis values as the “Swedish Iron,” commonly considered best for the cores of transformers and alternating-current magnets.

The following conclusions have been reached in the matter:

1. Iron and mild steel in the annealed state are more liable to change their hysteresis value by heating than when in the harder condition; (2) all changes are removed by re-annealing; (3) the changes thus produced by heating affect not only the amount of the hysteresis loss, but also the form of the lower part of the (B, H) curve.

**Forms of Electromagnet.**—The form which an electromagnet must take will greatly depend upon the purposes for which it is to be used. A design or form of electromagnet which will be very suitable for some purposes will be useless for others. Supposing it is desired to make an electromagnet which shall be capable of undergoing very rapid changes of strength, it must have such a form that the coercivity of the material is overcome by a self-demagnetizing force. This can be achieved by making the magnet in the form of a short and stout bar rather than a long thin one. It has already been explained that the ends or poles of a polar magnet exert a demagnetizing power upon the mass of the metal in the interior of the bar. If then the electromagnet has the form of a long thin bar, the length of which is several hundred times its diameter, the poles are very far removed from the centre of the bar, and the demagnetizing action will be very feeble; such a long thin electromagnet, although made of very soft iron, retains a considerable amount of magnetism after the magnetizing force is withdrawn. On the other hand, a very thick bar very quickly demagnetizes itself, because no part of the metal is far removed from the action of the free poles. Hence when, as in many telegraphic instruments, a piece of soft iron, called an armature, has to be attracted to the poles of a horseshoe-shaped electromagnet, this armature should be prevented from quite touching the polar surfaces of the magnet. If a soft iron mass does quite touch the poles, then it completes the magnetic circuit and abolishes the free poles, and the magnet is to a very large extent deprived of its self-demagnetizing power. This is the explanation of the well-known fact that after exciting the electromagnet and then stopping the current, it still requires a good pull to detach the keeper; but when once the keeper has been detached, the magnetism is found to have nearly disappeared. An excellent form of electromagnet for the production of very powerful fields has been designed by H. du Bois (fig. 6).

Various forms of electromagnets used in connexion with
ELECTROMETALLURGY

The present article, as explained under ELECTROCHEMISTRY, treats only of those processes in which electricity is applied to the production of chemical reactions or molecular changes at furnace temperatures. In many of these the application of heat is necessary to bring the substances used into the liquid state for the purpose of electrolysis, aqueous solutions being unsuitable. Among the earliest experiments in this branch of the subject were those of Sir H. Davy, who in 1807 (Phil. Trans., 1808, p. 1) produced the alkaline metals by passing an intense current of electricity from a platinum wire to a platinum dish, through a mass of fused caustic alkali. The alkali was started in the cold, the alkali being slightly moistened to render it a conductor; then, as the current passed, heat was produced and the alkali fused, the metal being deposited in the liquid condition. Later, A. Matthiessen (Quarterly Journ. Chem. Soc., viii. 30) obtained potassium by the electrolysis of a mixture of potassium and calcium chlorides fused over a lamp. There are here foreshadowed two types of electrolytic furnace-operations (a) those in which external heating maintains the electrolyte in the fused condition, and (b) those in which a current-density is applied sufficiently high to develop the heat necessary to effect this object unaided. Much of the earlier electrometallurgical work was done with furnaces of the (a) type, while nearly all the later developments have been with those of class (b). There is a third class of operations, exemplified by the manufacture of calcium carbide, in which electricity is employed solely as a heating agent; these are termed "electrothermal," as distinguished from "electrolytic." In certain electrothermal processes (e.g. calcium carbide production) the heat from the current is employed in raising mixtures of substances to the temperature at which a desired chemical reaction will take place between them, while in others (e.g. the production of graphite from coke or gas-carbon) the heat is applied solely to the production of molecular or physical changes. In ordinary electrothermal work only the continuous current may of course be used, but in electrothermal work an alternating current is equally available.

Electric Furnaces.—Independently of the question of the application of external heating, the furnaces used in electrometallurgy may be broadly classified into (i.) arc furnaces, in which the intense heat of the electric arc is utilized, and (ii.) resistance and incandescence furnaces, in which the heat is generated by an electric current overcoming the resistance of the inferior order.

Excepting such experimental arrangements as that of C. M. Despretz (C.R., 1849, 29) for use on a small scale in the laboratory, Picchou in France and J. H. Johnson in England in 1853, to have introduced the earliest practical form of furnace in this manner. These furnaces, which were similar if not identical, the furnace charge was crushed to a fine powder and passed through two or more electric arcs in succession. When used for ore smelting, the reduced metal and the accompanying slag were to be caught, after leaving the arc and while still liquid, in a hearth fired with ordinary fuel. Although this primitive furnace could be made to act, its efficiency was low, and the use of a separate fire was disadvantageous. In 1878 Sir William Siemens patented a form of furnace which is the type of a very large number of those designed by inventors.

In the best-known form a plumbago crucible was used with a hole cut in the bottom to receive a carbon rod, which was ground in so as to make a tight joint. This rod was connected with the positive pole of the dynamo or electric generator. The crucible was placed in a box-like form, having a cover of the same material, and was supported on it by a carbon rod of the same material, which was inserted from the inner side of the generator, and was suspended from one arm of a balance-beam, while from the other side of the beam was suspended a vertical hollow iron cylinder, which could be moved into or out of a wire coil or solenoid joined as a shunt across the two carbon rods of the furnace. The solenoid was above the iron cylinder, the supporting rod of which passed through it as a core. When the furnace with this well-known modification device was used, all the experiments were performed with two or more other conductors of electricity, the fragments of metal were placed in the crucible and the positive electrode was brought near them. Immediately the current passed through the solenoid it caused the iron cylinder to rise, and, by means of its supporting rod, forced the end of the balance beam upwards, so depressing the other end that the negative carbon rod was forced downwards into contact with the crucible.

This completed the circuit, and current passed freely from the positive carbon through the fragments of metal to the negative carbon, thereby reducing the metal to a solution through the heat generated by the passage of the electric current through the solenoid on the iron cylinder was automatically reduced, and that of the latter caused the negative carbon to rise, starting a reaction between the metal in the crucible and the counterpoise placed on the solenoid end of the balance beam to act against the attraction of the solenoid, the position of the counterpoise determining the length of the arc in the crucible. Any change in the resistance of the arc, either by change in the arc, or by removal of the charge in the crucible, or by the burning of the carbon affected the proportion of current flowing in the two shunt circuits, and so altered the temperature of the iron in the solenoid, and the position of the arc, within limits, automatically regulated. Were it not for the use of some such device the arc would be liable to constant fluctuation and to frequent extinction. The crucible was surrounded with a baffle of heat to minimize loss by radiation. The positive carbon was in some cases replaced by a water-cooled metal tube, or ferrule, closed, of course, at the end inserted in the crucible. Several modifications were proposed, in one of which, intended for the heating of non-conducting substances, the electrodes were passed horizontally through perforations in the upper part of the crucible walls, and the charge in the lower part of the crucible was heated by radiation.

The furnace used by Henri Moisson in his experiments on reactions at high temperatures, on the fusion and volatilization of the refractory materials, was of the former description. The charge was composed of borides of various metals, consisting, in its simplest form, of two superposed blocks of lime or of limestone with a central cavity cut in the lower block, and with a corresponding but much shallower inverted cavity in the upper block, which thus formed the lid of the furnace. Horizontal channels were cut on opposite walls, through which the carbon poles or electrodes were passed into the upper part of the cavity. Such a furnace, to take a current of 4 H.P. (say, of 60 amperes and 50 volts), measured externally about 6 by 6 by 7 in., and the electrodes were about 0.4 in. in diameter, while for a current of 100 H.P. (say, of 746 amperes and 100 volts) it measured about 14 by 14 by 14 in., and the electrodes were about 1.5 in. in diameter. In the latter case the crucible, which was placed in the cavity immediately beneath the arc, was about 3 in. in diameter (internally), and about 3.5 in. in height. The fact that energy is being used at a high rate of 100 H.P. so small a charge indicates that the furnace is used for experimental work, or for the fusion of metals which, like tungsten or chromium, can only be melted at temperatures attainable by electrical means. Moisson succeeded in fusing about 1 lb of either of these metals in 5 or 6 minutes in a furnace similar to that last described. He also arranged an experimental tube-furnace by passing a carbon tube horizontally beneath the arc.
practically limited to that at which the least easily vaporized material available for electrodes is converted into vapour. This material is carbon, and as its vaporizing point is (estimated at) over 3500° C., and less than 4000° C., the temperature of the electric furnace cannot rise much above 3500° C. (6330° F.); but H. Moissan showed that at this temperature the most stable of mineral combinations are dissociated, and the most refractory elements are converted into vapour, only certain borides, silicides, and metallic carbides having been found to resist the action of the heat. It is not necessary that all electric furnaces shall be run at these high temperatures; obviously, those of the incandescence or resistance type may be worked at any convenient temperature below the maximum. The electric furnace has several advantages as compared with some of the ordinary types of furnace, arising from the fact that the heat is generated from within the mass of material operated upon, and (unlike the blast-furnace, which presents the same advantage) without a large volume of gaseous products of combustion and atmospheric nitrogen being passed through it. In ordinary reverberatory and other heating furnaces the burning fuel is without the mass, so that the vessel containing the charge, and other parts of the plant, are raised to a higher temperature than would otherwise be necessary, in order to compensate for losses by radiation, convection and conduction. This advantage is especially noticeable in some cases in which the charge of the furnace is liable to attack the containing vessel at high temperatures, as it is often possible to maintain the outer walls of the electric furnace relatively cool, and even to keep them lined with a protecting crust of fused charge. Again, the construction of electric furnaces may often be exceedingly crude and simple; in the carborundum furnace, for example, the outer walls are of loosely piled bricks, and in one type of furnace the charge is simply heaped on the ground around the carbon resistance used for heating, without containing-walls of any kind. There is, however, one (not insuperable) drawback in the use of the electric furnace for the smelting of pure metals. Ordinarily carbon is used as the electrode material, but when carbon comes in contact at high temperatures with any metal that is capable of forming a carbide a certain amount of combination between them is inevitable, and the carbon thus introduced impairs the mechanical properties of the ultimate metallic product. Aluminium, iron, platinum and many other metals may thus take up so much carbon as to become brittle and unforgeable. It is for this reason that Siemens, Borchers and others substituted a hollow water-cooled metal block for the carbon cathode upon which the melted metal rests while in the furnace. Liquid metal coming in contact with such a surface forms a crust of solidified metal over it, and this crust thickens up to a certain point, namely, until the heat from within the furnace just overbalances that lost by conduction through the crust, and the crust just remains in a molten condition for a sufficient length of time to allow the oxygen in the charge of the furnace, every oxide would prove to be reducible by the action of carbon, and this prediction has in most instances been justified. Alumina and lime, for example, which cannot be reduced at ordinary furnace temperatures, readily give up their oxygen to carbon in the electric furnace, and then combine with an excess of carbon to form metallic carbides. In 1883 the brothers Cowles patented a process for the electrothermic reduction of metallic oxides by electrolysis of a very intense current of electricity when amalgamated with carbon in a retort. Later they patented a process for the reduction of aluminium by carbon, and in 1886 an electric furnace with sliding carbon rods passed through the end walls to the centre of a rectangular furnace. The impossibility of working with just sufficient carbon to reduce the alumina, without using any excess which would be free to
form at least so much carbide as would suffice, when diffused through the metal, to render it brittle, practically restricts the use of such processes to the production of aluminium alloys. Aluminium bronze (aluminium and copper) and ferro-aluminium (aluminium and iron) have been made in this way; the latter is the more satisfactory product, because a certain proportion of the iron is expected in an alloy of this character, as in ferromanganese and cast iron, and its presence is not objectionable. The furnace is built of fire-brick, and may measure (internally) 5 ft. in length by 1 ft. 8 in. in width, and 3 ft. in height. Into each end wall is built a short iron tube sloping downwards towards the centre, and through this is passed a bundle of five 3-in. carbon rods, bound together at the outer end by being cast into a head of cast iron for use with iron alloys, or of cast copper for aluminium bronze. This head slides freely in the cast iron tubes, and is connected by a copper rod with one of the terminals of the dynamo supplying the current. The carbons can thus, by the application of suitable mechanism, be withdrawn from or plunged into the furnace at will. In starting the furnace, the bottom is prepared by ramming it with charcoal-powder that has been soaked in milk of lime and water, so that each particle is coated with a film of lime, which serves to reduce the loss of current by oxidation. When the furnace is hot, a sheet iron case is then placed within the furnace, and the space between it and the walls is filled with lime; the interior is filled with fragments of iron or copper to be alloyed, mixed with alumina and coarse charcoal, broken pieces of carbon being placed in position to connect the electrodes. The iron case is then removed, the hole is covered with charcoal, and a cast iron cover with a central flue is placed above all. The current, either continuous or alternating, is then started, and continued for about 1 to 1½ hours, until the operation is complete, the carbon rods being gradually withdrawn as the action proceeds. In such a furnace a continuous current, for example, of 3000 amperes, at 50 to 60 volts, may be used at first, increasing to 5000 amperes in about half an hour. The reduction is not due to electrolysis, but to the action of carbon on alumina, a part of the charge in the carbon being consumed and evolved as carbon monoxide gas, which burns at the orifice in the cover so long as reduction is taking place. The reduced aluminium alloys itself immediately with the fused globules of metal in its midst, and as the charge becomes reduced the globules of alloy unite until, in the end, they are run out of the tap-hole after the current has been diverted to another furnace. It was found in practice (in 1889) that the expenditure of energy per pound of reduced aluminium was about 23 H.P.-hours, a number considerably in excess of that required at the present time for the production of pure aluminium by the electrolytic process described in the article Aluminium. Calcium carbide, graphite (q.v.), phosphorus (q.v.) and carbonarundum (q.v.) are now extensively manufactured by the operations outlined above.

**ELECTRICITY**—The isolation of the metals sodium and potassium by Sir Humphry Davy in 1807 by the electrolysis of the fused hydroxides was one of the earliest applications of the electric current to the extraction of metals. This pioneering work showed little development until about the middle of the 19th century, when magnesium was isolated electrolytically by R. Bunsen, and this process subsequently received much attention at the hands of Moissan and Borchers. Two years later Bunsen and H. E. Sainte Claire Deville working independently obtained aluminium (q.v.) by the electrolysis of the fused double sodium aluminium chloride. Since that date other processes have been devised and the electrolytic processes have entirely replaced the older methods. Reduction of carbon is the method of production of calcium (q.v.), which have had the effect of converting a laboratory curiosity into a product of commercial importance. Barium and strontium have also been produced by electrolytic metallurgical methods, but the processes have only a laboratory interest at present. Lead, zinc and other metals have also been reduced in this manner.

(W. G. M.)

**ELECTROMETER**, an instrument for measuring difference of potential, which operates by means of electrostatic force and gives the measurement either in arbitrary or in absolute units (see UNITS, PHYSICAL). In the last case the instrument is called an absolute electrometer. Lord Kelvin has classified electrometers into (1) Repulsion, (2) Attracted diak, and (3) Symmetrical electrometers (see W. Thomson, Brit. Assoc. Report, 1865, or Reprinted Papers on Electrostatics and Magnetisation, p. 261).

Repulsion Electrometers.—The simplest form of repulsion electrometer is W. Henley's pith ball electrometer (Phil. Trans., 1777, I, p. 359) in which the repulsion of a straw ending in a pith ball from a fixed stem is indicated on a graduated arc (see ELECTROSCOPE). A double pith ball repulsion electrometer was employed by T. Cavallio in 1777.

It may be pointed out that such an arrangement is not merely an arbitrary electrometer, but may become an absolute electrometer within certain rough limits. Let two spherical pith balls of radius $r$ and weight $W$, covered with gold-leaf so as to be conducting, be suspended by parallel silk threads of length $l$ and of just to touch each other. If then the balls are both charged to a potential $V$ they will repel each other, and the threads will stand out at an angle $\theta$, which can be observed on a protractor. Since the electrical repulsion of the balls is equal to $CV^2/2\sin \theta$ dynes, where $C = \pi r^2$ is the capacity of the two balls, and this force is balanced by the restoring force due to their weight, $Wg$ dynes, where $g$ is the acceleration of gravity, it is easy to show that we have

$$V = \frac{2l \sin \theta}{Wg \tan \theta}$$

as an expression for their common potential $V$, provided that the balls are small and their distance sufficiently great not to disturb the uniformity of electric charge upon them. Observation of $\theta$ with measurement of the value of $l$ and $r$ reckoned in centimetres and $W$ in grammes gives us the potential difference of the balls in absolute C.G.S. or electrostatic units. The gold-leaf electroscope invented by Abraham Bennet (see ELECTROSCOPE) can in like manner, by the addition of a scale to observe the divergence of the gold-leaves, be made a repulsion electrometer.

**Attracted Disk Electrometers.**—A form of attracted disk absolute electrometer was devised by A. Volta. It consisted of a plane conducting plate forming one pan of a balance which was suspended over another insulated plate which could be electrified. The attraction between the two plates was balanced by a weight put in the opposite pan. A similar electric balance was subsequently devised by Sir W. Snow-Harris,1 one of whose instruments is shown in fig. 1. C is an insulated disk over which is suspended another disk attached to the arm of a balance. A weight is put in the opposite scale pan and a measured charge of electricity is given to the disk C just sufficient to tip over the balance. Snow-Harris found that this charge varied as the square root of the weight in the opposite pan, thus showing that the

1 It is probable that an experiment of this kind had been made as far back as 1746 by Daniel Grahame of Danzig, who has some claims to have suggested the word "electrometer" in connexion with it. See Park Benjamin, The Intellectual Rise in Electricity (London, 1895), p. 542.

**FIG. 1.**—Snow-Harris's Disk Electrometer.
attraction between the disks at given distance apart varies as the square of their difference of potential.

The most important improvements in connexion with electrometers are due, however, to Lord Kelvin, who introduced the guard plate and used gravity or the torsion of a wire as a means for evaluating the electrical forces.

His portable electrometer is shown in fig. 2. H H (see fig. 3) is a plane disk of metal called the guard plate, fixed to the inner coating of a small Leyden jar (see fig. 2). At F a small hole is cut out of H H, and into this fits loosely without touching, like a trap door, a square piece of aluminium foil having a projecting tail, which carries at its end a spiral L, crossed by a fine hair (see fig. 3). The square piece of aluminium is placed round a horizontal stretched wire. If then another horizontal disk G is placed over the disk H H and a difference of potential made between G and H H, the movable aluminium trap door F will be attracted by the fixed plate G. Matters are so arranged by giving a torsion to the wire carrying the aluminium disk F that for a certain potential difference between the plates H and G, the movable part F comes into a definite sighted position, which is observed by means of a small lens. The plate G (see fig. 2) is moved up and down, parallel to itself, by means of a screw. In using the instrument the conductor, whose potential is to be tested, is connected to the plate G. Let this potential be denoted by V, and let s be the potential of the guard plate and the aluminium flap. This last potential is maintained constant by guard plate and flap being part of the interior coating of a charged Leyden jar. Since the distribution of electricity may be considered to be constant over the surface S of the attracted disk, the mechanical force f on it is given by the expression

$$f = \frac{5(V - p)S}{6d^2},$$

where d is the distance between the two plates. If this distance is varied until the attracted disk comes into a definite sighted position as seen by observing the end of the index through the lens, then since the force f is constant, being due to the torque applied by the wire for a definite angle of twist, it follows that the difference of potential of the two plates varies as their distance. If then two experiments are made, first with the upper plate connected to earth, and secondly, connected to the object being tested, we get an expression for the potential V of this conductor in the form

$$V = A(d' - d),$$

where d and d' are the distances of the fixed and movable plates from one another in the two cases, and A is some constant. We thus find V in terms of the constant and the difference of the two screw readings.

Lord Kelvin's absolute electrometer (fig. 4) involves the same principle. There is a certain fixed guard disk B having a hole in it which is loosely occupied by an aluminium trap door plate, shielded by D and suspended on springs, so that its surface is parallel with that of the guard plate. Parallel to this is a second movable plate A, the distances between the two being measurable by means of a screw. The movable plate can be drawn down into a definite sighted position when a difference of potential is made between the two plates. This sighted position is such that the surface of the trap door plate is level with that of the guard plate, and is determined by observations made with the lenses H and L. The movable plate can then be thus depressed by placing on it a certain standard weight W grams.

Suppose it is required to measure the difference of potentials V and V' of two conductors. First one and then the other conductor is connected with the electrode of the lower or movable plate, which is moved by the screw until the index attached to the attracted disk shows it to be in the sighted position. Let the screw readings in the two cases be d and d'. If W is the weight required to depress the attracted disk into the same sighted position when the plates are unelecrtified and g is the acceleration of gravity, then the difference of potentials of the conductors tested is expressed by the formula

$$V - V' = (d - d') \frac{5W}{Sg},$$

where S denotes the area of the attracted disk.

The difference of potentials is thus determined in terms of a weight, an area and a distance, in absolute C.G.S. measure or electrostatic units.

Symmetrical Electrometers include the dry pile electrometer and Kelvin's quadrant electrometer. The principle underlying these instruments is that we can measure differences of potential by means of the motion of an electrified body in a symmetrical field of electric force. In the dry pile electrometer a single gold-leaf is hung up between two plates which are connected to the opposite terminals of a dry pile so that a certain constant difference of potential exists between these plates. The original inventor of this instrument was T. G. B. Behrens (Gibb. Ann., 1860, 23), but it generally bears the name of J. G. F. von Bohnenberger, who slightly modified its form. G. T. Fechner introduced the important improvement of using only one pile, which he removed from the immediate neighbourhood of the suspended leaf. W. G. Hanke still further improved the dry pile electrometer by giving a slow motion movement to the two plates, and substituted a galvanic battery with a large number of cells for the dry pile, and also employed a divided scale to measure the movements of the gold-leaf (Pogg. Ann., 1858, 103). If the gold-leaf is unelecrtified, it is not acted upon by the two plates placed at equal distances on either side of it, but if its potential is raised or lowered it is attracted by one disk and repelled by the other, and the displacement becomes a measure of its potential.

A vast improvement in this instrument was made by the invention of the quadrant electrometer by Lord Kelvin, which is the most sensitive form of electrometer yet devised. In this instrument (see fig. 5) a flat paddle-shaped needle of aluminium foil U is supported by a bifilar suspension consisting of two cocoon fibres. This needle is suspended in the interior of a glass vessel partly coated with tin-foil on the outside and inside, forming therefore a Leyden jar (see fig. 6). In the bottom of the vessel is placed some sulphuric acid, and a platinum wire attached to the suspended needle dips into this acid. By giving a charge to this Leyden jar the needle can thus be maintained at a certain constant high potential. The needle is enclosed by a sort of flat box divided into four insulated quadrants A, B, C, D (fig. 5), whence the name. The opposite quadrants are connected together by thin platinum wires. These quadrants are insulated.

---

1 See Maxwell, Treatise on Electricity and Magnetism (2nd ed.), i. 308.
necessarily obey a law of deflection making the deflections proportional to the potential difference of the quadrants, but that an electrometer can be constructed which does fulfill the above law. The importance of this investigation resides in the fact that an electrometer of the above pattern can be used as a wattmeter (q.e.), provided that the deflection of the needle is proportional to the potential difference of the quadrants. This use of the instrument was proposed simultaneously in 1881 by Professors Ayrton and G. F. Fitzgerald and M. A. Potter. Suppose we have an inductive and a non-inductive circuit in series, which is traversed by a periodic current, and that we desire to know the power being absorbed by the inductive circuit. Let $v_1$, $v_2$, $v_3$ be the instantaneous potentials of the two ends and middle of the circuit; let a quadrant electrometer be connected first with the quadrants to the two ends of the inductive circuit and the needle to the far end of the inductive circuit, and then secondly with the needle connected to one of the quadrants (see fig. 5). Assuming the electrometer to obey the above-mentioned theoretical law, the first reading is proportional to $v_1 - v_2$, $\frac{v_1 - v_3 + v_2}{2}$ and the second to $v_1 - v_2$, $\frac{v_1 - v_3 + v_2}{2}$.

The difference of the readings is then proportional to $(v_1 - v_2)(v_1 - v_3)$.

But this last expression is proportional to the instantaneous power taken up in the inductive circuit, and hence the difference of the two readings of the electrometer is proportional to the mean power taken up in the circuit (Phil. Mag., 1891, 32, p. 266). Ayrton and Perry and also P. R. Blondlot and P. Curie agreed with Hopkinson that a single electrometer could be constructed with two pairs of quadrants and a duplicate needle on one stem, so as to make two readings simultaneously and produce a deflection proportional to the power being taken up in the inductive circuit.

Quadrant electrometers have also been designed especially for measuring extremely small potential differences. An instrument of this kind has been constructed by Dr. F. Dolezalek (fig. 7). The needle and quadrants are of small size, and the electrostatic capacity is correspondingly small. The quadrants are mounted on pillars of amber which afford a very high insulation. The needle, a piece of paddle-shaped paper thinly coated with silver foil, is suspended by a quartz fibre, its extreme lightness making it possible to use a very feeble controlling force without rendering the period of oscillation unduly great. The resistance offered by the air to a needle of such light construction suffices to render the motion nearly dead-beat. Throughout a wide range the deflections are proportional to the potential difference producing them. The needle is charged to a potential

---

of 50 to 200 volts by means of a dry pile or voltaic battery, or from a lighting circuit. To facilitate the communication of the charge to the needle, the quartz fibre and its attachments are rendered conductive by a thin film of solution of hygroscopic salt such as calcium chloride. The lightness of the needle enables the instrument to be moved without fear of damaging the suspension. The upper end of the quartz fibre is rotated by a torsion head, and a metal cover serves to screen the instrument from stray electrostatic charges. With a quartz fibre 0.000 mm. thick and 60 mm. long, the needle being charged to 110 volts, the period and swing of the needle was 18 seconds. With the scale at a distance of two metres, a deflection of 130 mm. was produced by an electromotive force of 0.1 volt. By using a quartz fibre of about half the above diameter the sensitiveness was much increased. An instrument of this form is valuable in measuring small alternating currents by the fall of potential produced down a known resistance. In the same way it may be employed to measure high potentials by measuring the fall of potential down a fraction of a known non-inductive resistance. In this last case, however, the capacity of the electrometer used must be small, otherwise an error is introduced.

See, in addition to references already given, A. Gray, Absolute Measuring Instruments and Machines (London, 1880), p. 254; A. Winkelmann, Handbuch der Physik (Breslau, 1905), pp. 58-70, which contains a large number of references to original papers on electrometers.

The same suggestion by Dr G. Johnstone Stoney in 1891 for the natural unit of electricity to which he had drawn attention in 1874, and subsequently applied to the ultra-atomic particles carrying negative charges of electricity, of which Professor Sir J. J. Thomson proved in 1897 that the cathode rays consisted. The electrons, which Thomson at first called corpuscles, are point charges of negative electricity, their inertia showing them to have a mass equal to about \( \frac{1}{1836} \) that of the hydrogen atom. They are apparently derivable from all kinds of matter, and are believed to be components and integral parts of the chemical atom. The electronic theory of the chemical atom supposes, in fact, that atoms are conglomerates of electrons in rapid orbital motion. The size of the electron is to that of an atom roughly in the ratio of a pin's head to the dome of St Paul's cathedral.

The electron is always associated with the unit charge of negative electricity, and it has been suggested that its inertia is wholly electrical. For further details see the articles on ELECTRICITY, MAGNETISM, MATTER, RADIOACTIVITY, CONDUCTION, ELECTRICITY; and the original papers of Dr G. Johnstone Stoney, Proc. Brit. Ass. (Belfast, August 1874), On the Physical Units of Nature, and Trans. Royal Dublin Society (1851), 4, p. 583.

**ELECTROPHORUS**

An instrument invented by Alessandro Volta in 1775, by which mechanical work is transformed into electrostatic charge by the aid of a small initial charge of electricity. The operation depends on the facts of electrostatic induction discovered by John Canton in 1753, and, independently, by J. K. Wilcke in 1762 (see ELECTRICITY). Volta, in a letter to J. Priestley on the 10th of June 1775 (see Collezioni dell'opere, ed. 1816, vol. i. p. 118), described the invention of a device he called un elettrofore perpetuo, based on the fact that a conductor held near an electrified body and touched by the finger was charged, when withdrawn, to possess an electric charge of opposite sign to that of the electrified body. His electrophorus in one form consisted of a disk of non-conducting material, such as pitch or resin, placed between two metal sheets, one being provided with an insulating handle. For the pitch or resin may be substituted a sheet of glass, ebonite, indiarubber or any other good dielectric placed upon a metallic sheet, called the sole-plate.

With a quartz fibre 0.000 mm. thick and 60 mm. long, the needle being charged to 110 volts, the period and swing of the needle was 18 seconds. With the scale at a distance of two metres, a deflection of 130 mm. was produced by an electromotive force of 0.1 volt. By using a quartz fibre of about half the above diameter the sensitiveness was much increased. An instrument of this form is valuable in measuring small alternating currents by the fall of potential produced down a known resistance. In the same way it may be employed to measure high potentials by measuring the fall of potential down a fraction of a known non-inductive resistance. In this last case, however, the capacity of the electrometer used must be small, otherwise an error is introduced.

See, in addition to references already given, A. Gray, Absolute Measuring Instruments and Machines (London, 1880), p. 254; A. Winkelmann, Handbuch der Physik (Breslau, 1905), pp. 58-70, which contains a large number of references to original papers on electrometers.

The same suggestion by Dr G. Johnstone Stoney in 1891 for the natural unit of electricity to which he had drawn attention in 1874, and subsequently applied to the ultra-atomic particles carrying negative charges of electricity, of which Professor Sir J. J. Thomson proved in 1897 that the cathode rays consisted. The electrons, which Thomson at first called corpuscles, are point charges of negative electricity, their inertia showing them to have a mass equal to about \( \frac{1}{1836} \) that of the hydrogen atom. They are apparently derivable from all kinds of matter, and are believed to be components and integral parts of the chemical atom. The electronic theory of the chemical atom supposes, in fact, that atoms are conglomerates of electrons in rapid orbital motion. The size of the electron is to that of an atom roughly in the ratio of a pin's head to the dome of St Paul's cathedral.

The electron is always associated with the unit charge of negative electricity, and it has been suggested that its inertia is wholly electrical. For further details see the articles on ELECTRICITY, MAGNETISM, MATTER, RADIOACTIVITY; CONDUCTION, ELECTRICITY; and the original papers of Dr G. Johnstone Stoney, Proc. Brit. Ass. (Belfast, August 1874), On the Physical Units of Nature, and Trans. Royal Dublin Society (1851), 4, p. 583.

**ELECTROPHORUS**

An instrument invented by Alessandro Volta in 1775, by which mechanical work is transformed into electrostatic charge by the aid of a small initial charge of electricity. The operation depends on the facts of electrostatic induction discovered by John Canton in 1753, and, independently, by J. K. Wilcke in 1762 (see ELECTRICITY). Volta, in a letter to J. Priestley on the 10th of June 1775 (see Collezioni dell'opere, ed. 1816, vol. i. p. 118), described the invention of a device he called un elettrofore perpetuo, based on the fact that a conductor held near an electrified body and touched by the finger was charged, when withdrawn, to possess an electric charge of opposite sign to that of the electrified body. His electrophorus in one form consisted of a disk of non-conducting material, such as pitch or resin, placed between two metal sheets, one being provided with an insulating handle. For the pitch or resin may be substituted a sheet of glass, ebonite, indiarubber or any other good dielectric placed upon a metallic sheet, called the sole-plate.  

With a quartz fibre of about half the above diameter the sensitiveness was much increased. An instrument of this form is valuable in measuring small alternating currents by the fall of potential produced down a known resistance. In the same way it may be employed to measure high potentials by measuring the fall of potential down a fraction of a known non-inductive resistance. In this last case, however, the capacity of the electrometer used must be small, otherwise an error is introduced.

See, in addition to references already given, A. Gray, Absolute Measuring Instruments and Machines (London, 1880), p. 254; A. Winkelmann, Handbuch der Physik (Breslau, 1905), pp. 58-70, which contains a large number of references to original papers on electrometers.

The same suggestion by Dr G. Johnstone Stoney in 1891 for the natural unit of electricity to which he had drawn attention in 1874, and subsequently applied to the ultra-atomic particles carrying negative charges of electricity, of which Professor Sir J. J. Thomson proved in 1897 that the cathode rays consisted. The electrons, which Thomson at first called corpuscles, are point charges of negative electricity, their inertia showing them to have a mass equal to about \( \frac{1}{1836} \) that of the hydrogen atom. They are apparently derivable from all kinds of matter, and are believed to be components and integral parts of the chemical atom. The electronic theory of the chemical atom supposes, in fact, that atoms are conglomerates of electrons in rapid orbital motion. The size of the electron is to that of an atom roughly in the ratio of a pin's head to the dome of St Paul's cathedral.

The electron is always associated with the unit charge of negative electricity, and it has been suggested that its inertia is wholly electrical. For further details see the articles on ELECTRICITY, MAGNETISM, MATTER, RADIOACTIVITY; CONDUCTION, ELECTRICITY; and the original papers of Dr G. Johnstone Stoney, Proc. Brit. Ass. (Belfast, August 1874), On the Physical Units of Nature, and Trans. Royal Dublin Society (1851), 4, p. 583.

**ELECTROPLATING**

The art of depositing metals by the electric current. In the article ELECTROLYSIS it is shown how the passage of an electric current through a solution containing metallic ions involves the deposition of the metal on the cathode. Similarly, the metal in course of time polymerises, and in this way a film is formed on the cathode. This film is a tenacious film, which adheres to the cathode, and the metal is deposited on it. In this way, the electric current can be used to deposit metals on surfaces. The process is called electroplating.  

ELECTROPLATING

cost on plated wares of all kinds is of the utmost importance, the greatest care must be taken to ensure its complete adhesion. This can only be effected if the surface of the metal on which the deposit is to be made is chemically clean. Grease must be removed by potash, whiting or other means, and tannish by an acid or potassium cyanide, washing in plenty of water being resorted to after each operation. The vats for depositing may be of enamelled iron, slate, glazed earthenware, glass, lead-lined wood, &c. The current densities and potential differences frequently used for some of the commoner metals are given in the following table, taken from 'McMillan's Treatise on Electro-metallurgy.' It must be remembered, however, that variations in conditions modify the electromotive force required for any given process. For example, a rise in temperature of the bath causes an increase in its conductivity, so that a lower E.M.F. will suffice to give the required current density; on the other hand, an abnormally great distance between the electrodes, or a diminution in acidity of an acid bath, or in the strength of the solution used, will increase the resistance, and so require the application of a higher E.M.F.

Large objects are suspended in the tanks by hooks or wires, care being taken to shift their position and so avoid wire-marks. Small objects are often heaped together in perforated trays or ladles, the cathode connecting-rod being buried in the midst of them. These require constant shifting because the objects are in contact at many points, and because the top ones shield those below from the depositing action of the current. Hence processes have been patented in which the objects to be plated are suspended in revolving drums between the anodes, the rotation of the drum causing the constant renewal of surfaces and affording a burnishing action at the same time. Care must be taken not to expose goods in the plating-bath to too high a current density, else they may be "burnt"; they must never be exposed one at a time to the full anode surface, with the current flowing as in the hot bath, but either one piece at a time should be replaced, or some of the anodes should be transferred temporarily to the place of the cathodes, in order to distribute the current over a sufficient cathode-area. Burnt deposits are dark-coloured, or even pulvurulent and useless. The strength of the current may also be regulated by introducing lengths of German silver or iron wire, carbon rod, or other inferior conductors in the path of the current, and a series of such resistances should always be provided close to the tanks. Ammeters to measure the volume, and voltimeters to determine the pressure of current supplied to the tanks, should also be provided. Very irregular surfaces may require the use of specially shaped anodes in order that the distance between the electrodes may be fairly uniform, otherwise the portion of the cathode lying nearest to the anode may receive an undue share of the current, and therefore a greater thickness of coat. Supplementary anodes are sometimes used in difficult cases of this kind. Large metallic surfaces (especially external surfaces) are sometimes plated by means of a "doctor," which, in its simplest form, is a brush constantly wetted with the electrolyte, with a wire anode buried amid the hairs or bristles; this brush is painted slowly over the surface of the metal to be coated, which must be connected to the negative terminal of the electrical generator. Under these conditions electrolysis of the solution in the brush takes place. Iron ships' plates have recently been coated with copper in sections (to prevent the adhesion of barnacles), by building up a temporary trough against the side of the ship, making the thoroughly cleaned plate act both as cathode and as one side of the trough. Decorative plating-work in several colours (e.g. "parcel-gilding") is effected by painting a portion of an object with a stopping. (i.e. a non-conducting) varnish, such as copal varnish, so that this portion is not coated. The varnish is then removed, a different design stopped out, and another metal deposited. By varying this process, designs in metals of different colours may readily be obtained.

Reference must be made to the textbooks (see ELECTROCHEMISTRY) for a full account of the very varied solutions and methods employed for electroplating with silver, gold, copper, iron and nickel. It should be mentioned here, however, that solutions which would deposit their metal on any object by simple immersion should not be generally used for electroplating that object, as the resulting deposit is usually non-adhesive. For this reason the acid copper-bath is not used for iron or zinc objects, a bath containing copper cyanide or oxide dissolved in potassium cyanide being substituted. This solution, being an inferior conductor of electricity, requires a much higher electromotive force to drive the current through it, and is therefore more costly in use. It is, however, commonly employed hot, whereby its resistance is reduced. Zinc is commonly deposited by electrolysis on iron or steel goods which would ordinarily be "galvanised," but which for any reason may not conveniently be treated by the method of immersion in fused zinc. The zinc cyanide bath may be used for small objects, but for heavy goods the sulphate bath is employed. Sheard Cowper-Coles patented a process in which, working with a high current density, a lead anode is used, and powdered zinc is kept suspended in the solution to maintain the proportion of zinc in the electrolyte, and so to guard against the gradual acidification of the bath. Cobalt is deposited by a method analogous to that used for its sister-metal nickel. Platinum, palladium, and tin are occasionally deposited for special purposes. In the deposition of gold the colour of the deposit is influenced by the presence of impurities in the solution; when copper is present, some is deposited with the gold, imparting to it a reddish colour, whilst a little silver gives it a greenish shade. Thus so-called coloured-gold deposits may be produced by the judicious introduction of suitable impurities. Even pure gold, it may be noted, is darker or lighter in colour according to the impurity: to make it a more brilliant yellow, the electro-deposition of brass—mainly on iron wire, such as bedstead tubes—is now very widely practised, the bath employed being a mixture of copper, zinc and potassium cyanides, the proportions of which vary according to the character of the brass required, and to the mode of treatment. The colour depends in part upon the proportion of copper and zinc, and in part upon the current density, weaker currents tending to produce a redder or yellower metal. Other alloys may be produced, such as bronze, or German silver, by selecting solutions (usually cyanides) from which the current is able to deposit the constituent metals simultaneously.

Electrolysis has in a few instances been applied to processes of manufacture. For example, Wilde produced copper plating surfaces for calico printing-rollers and the like by immersing rotating iron cylinders as cathodes in a copper bath. Elmore, Dumoulin, Cowper-Coles and others have prepared copper cylinders and plates by depositing copper on rotating mandrels with special arrangements. Others have arranged a means of obtaining high conductivity wire from cathode-copper without fusion, by depositing the metal in the form of a spiral strip on a cylinder, the strip being subsequently drawn down in the usual way; at present, however, the ordinary methods of wire
production are found to be cheaper. J. W. Swan (Journ. Inst. Elec. Eng., 1898, vol. xxvii. p. 16) also worked out, but did not proceed with, a process in which a copper wire whilst receiving a deposit of copper was continuously passed through the draw-plate, and thus indefinitely extended in length. Cowper-Coles (Journ. Inst. Elec. Eng., 1898, 27, p. 99) very successfully produced true parabolic reflectors for projectors, by depositing copper upon carefully ground and polished glass surfaces rendered conductive by a film of deposited silver.

**Electroscope**, an instrument for detecting differences of electric potential and hence electrification. The earliest form of scientific electroscope was the versorium or electrical needle of William Gilbert (1544–1603), the celebrated author of the treatise *De magnete* (see ELECTRICITY). It consisted simply of a light metallic needle balanced on a pivot like a compass needle. Gilbert employed it to prove that numerous other bodies besides amber are susceptible of being electrified by friction. In this case the visible indication consisted in the attraction exerted between the electrified body and the light pivoted needle which was acted upon and electrified by induction. The next improvement was the invention of simple forms of repulsion electroscope. Two similarly electrified bodies repel each other. Benjamin Franklin employed the repulsion of two linen threads, C. F. de C. du Fay, J. Canton, W. Henley and others devised the pith ball, or double straw electroscope (fig. 1). T. Cavallo about 1770 employed two fine silver wires terminating in pith balls suspended in a glass vessel having strips of tin-foil pasted down the sides (fig. 2). The object of the thimble-shaped dome was to keep moisture from the stem from which the pith balls were supported, so that the apparatus could be used in the open air even in the rainy weather. Abraham Bennet (Phil. Trans., 1787, 77, p. 26) invented the modern form of gold-leaf electroscope. Inside a glass shade he fixed to an insulated wire a pair of strips of gold-leaf (fig. 3). The wire terminated in a plate or knob outside the vessel. When an electrified body was held near or in contact with the knob, repulsion of the gold leaves ensued. Volta added the condenser (Phil. Trans., 1783), which greatly increased the power of the instrument. M.

It was necessary to place a cylinder of metallic gauze connected to the earth inside the vessel, or better still, to line the glass shade with tin-foil connected to the earth and observe through a hole the indications of the gold leaves (fig. 4). Leaves of aluminium foil may with advantage be substituted for gold-leaf, their use being preferable when a large scale is sometimes added to indicate the angular divergence of the leaves.

The uses of an electroscope are, first, to ascertain if any body is in a state of electrification, and secondly, to indicate the sign of that charge. In connexion with the modern study of radioactivity, the electroscope has become an instrument of great usefulness, far outrivalling the spectroscope in sensibility. Radio-active bodies are chiefly recognized by the power they have of rendering the air in their neighbourhood conductive; hence the electroscope detects the presence of a radio-active body by losing an electric charge given to it more quickly than it would otherwise do. A third great use of the electroscope is therefore to detect electric conductivity either in the air or in any other body.

To detect electrification it is best to charge the electroscope by induction. If an electrified body is held near the gold-leaf electroscope the leaves diverge with electricity of the same sign as that of the body being tested. If, without removing the electrified body, the plate or knob of the electroscope is touched, the leaves collapse. If the electroscope is insulated once more and the electrified body removed, the leaves again diverge with electricity of the opposite sign to that of the body being tested. The sign of charge is then determined by holding near the electroscope a glass rod rubbed with silk or a sealing-wax rod rubbed with flannel. If the approach of the glass rod causes the leaves in their final state to collapse, then the charge in the rod was positive, but if it causes them to expand still more the charge was negative, and vice versa for the sealing-wax rod. When employing a Volta condensing electroscope, the following is the method of procedure:—The top of the electroscope consists of a flat, smooth plate of lacquered brass on which another plate of brass rests, separated from it by three minute fragments of glass or shellac, or a film of shellac varnish. If the electrified body is touched against the upper plate whilst at the same time the lower plate is put to earth, the condenser formed of the two plates and the film of air or varnish becomes charged with positive electricity on the one plate and negative on the other. On insulating the lower plate and raising the upper plate by the glass handle, the capacity of the condenser formed by the plates has vastly decreased, but since the charge on the lower plate including the gold leaves attached to it remains the same, as the capacity of the system is reduced the potential is raised and therefore the gold leaves diverge widely. Volta made use of such an electroscope in his celebrated experiments (1790–1800) to prove that metals placed in contact with one another are brought to different potentials, in other words to prove the existence of so-called contact electricity. He was assisted to detect the small potential differences then in question by the use of a multiplying condenser or revolving doubler (see ELECTRICAL MACHINE). To employ the electroscope as a means of detecting radio-activity, we have first to test the leakage quality of the electroscope itself. Formerly it was usual to insulate the rod of the electroscope by passing it through a hole in a cork or mass of sulphur fixed in the top of the glass vessel within which the gold leaves were suspended. A further improvement consisted in passing the metal wire to which the gold leaves were attached through a glass tube much wider than the rod, the latter being fixed concentrically in the glass tube by means of solid shellac melted and run in. This insulation, however, is not sufficiently good for an electroscope intended for the detection of radio-activity; for this purpose

**Fig. 2.**—Cavallo's Electroscope.

**Fig. 3.**—Bennet's Electroscope.

**Fig. 4.**—Gold-Leaf Electroscope.

Faraday, however, showed long subsequently that to bestow upon the indications of such an electroscope definite meaning

See the English translation by the Gilbert Club of Gilbert's *De magnete*, p. 49 (London, 1900).
it must be such that the leaves will remain for hours or days in a state of steady divergence when an electrical charge has been given to them.

In their researches on radio-activity M. and Mme P. Curie employed an electroscope made as follows:—A metal case (fig. 5), having two holes in its sides, has a vertical brass strip B attached to the inside of the lid by a block of sulphur SS or any other good insulator. Joined to the strip is a transverse wire, terminating at one end in a knob C and at the other end in a condenser plate P. The strip B carries also a strip of gold-leaf L, and the metal case is connected to earth. If a charge is given to the electroscope, and if any radio-active material is placed on a condenser plate P attached to the outer case, then that substance stows conductivity on the air between the plates P and P', and the charge of the electroscope begins to leak away. The collapse of the gold-leaf is observed through an aperture in the case by a microscope, and the time taken by the gold-leaf to fall over a certain distance is proportional to the ionizing current, that is, to the intensity of the radio-activity of the substance.

A very similar form of electroscope was employed by J. P. L. J. Elster and H. F. K. Geitel (fig. 6), and also by C. T. R. Wilson (see Proc. Roy. Soc., 1901, 68, p. 152). A metal box has a metal strip B suspended from a block or insulator by means of a bit of sulphur or amber S, and to it is fastened a strip of gold-leaf L. The electroscope is provided with a charging rod C. In a dry atmosphere sulphur or amber is an early perfect insulator, and hence if the air in the interior of the box is kept dry by calcium chloride, the electroscope will hold its charge for a long time. Any divergence or collapse of the gold-leaf can be viewed by a microscope through an aperture in the side of the case.

Another type of sensitive electroscope is one devised by C. T. R. Wilson (Proc. Cam. Phil. Soc., 1903, 12, part 2). It consists of a metal box placed on a tilting stand (fig. 7). At one end is an insulated plate P kept at a potential of 200 volts or so above the earth by a battery. At the other end is an insulated metal wire having attached to it a thin strip of gold-leaf L. If the plate P is electrified it attracts the strip which stretches out towards it. Before use the strip is for some moment connected to the case, and the arrangement is then tilted until the strip extends at a certain angle. If then the strip of gold-leaf is raised or lowered in potential it moves to or from the plate P, and its movement can be observed by a microscope through a hole in the side of the box. There is a particular angle of tilt of the case which gives a maximum sensitivity. Wilson found that with the plate electrified to 207 volts and with a tilt of the case of 30°, if the gold-leaf was raised one volt in potential above the case, it moved over 200 divisions of the micrometer scale in the eye-piece of the microscope, 54 divisions being equal to one millimetre. In using the instrument the insulated rod to which the gold-leaf is attached is connected to the conductor, the potential of which is being examined. In the use of all these electrosopic instruments it is essential to bear in mind (as first pointed out by Lord Kelvin) that what a gold-leaf electroscope really indicates is the difference of potential between the gold-leaf and the solid walls enclosing the air space in which they move. If these enclosing walls are made of anything else than perfectly conducting material, then the indications of the instrument may be uncertain and meaningless. As already mentioned, Faraday remedied this defect by coating the inside of the glass vessel in which the gold-leaves were suspended to form an electroscope with tinfoil (see fig. 4).

In spite of these admonitions all but a few instrument makers have continued to make the vicious type of instrument consisting of a pair of gold-leaves suspended within a glass shade or bottle, no means being provided for keeping the walls of the vessel continually at zero potential.

**ELECTROSTATICS**, the name given to that department of electrical science in which the phenomena of electricity at rest are considered. Besides their ordinary condition all bodies are capable of being thrown into a physical state in which they are said to be electrified or charged with electricity. When in this condition they become sources of electric force, and the space round them in which this force is manifested is called an "electric field" (see Electricity). Electrified bodies exert mechanical forces on each other, creating or tending to create motion, and also induce electric charges on neighbouring surfaces.

The reader possessed of no previous knowledge of electrical phenomena will best appreciate the terms employed by the aid of a few simple experiments. We present the following apparatus and proceed to provide:—(1) two small metal tea-trays and some clean dry tumblers, the latter preferably varnished with shellac varnish made with alcohol free from water; (2) a sheet of ebonite rather larger than the tea-trays; (3) a rod of sealing-wax or ebonite and a glass tube, also some pieces of silk and flannel; (4) a few small gilt pitch balls suspended by dry silk threads; (g) a gold-leaf electroscope, and, if possible, a simple form of quadrant electrometer (see Electroscope and Electrometer); (6) some brass balls mounted on the ends of ebonite penholders, and a few tin canisters. With the aid of this apparatus, the principal facts of electrostatics can be experimentally verified, as follows:

**Experiment I.**—Place one tea-tray bottom side uppermost upon three warm tumblers as legs. Rub the sheet of ebonite vigorously with warm flannel and lay it rubbed side downwards on the top of the tray. Touch the tray with the finger for an instant, and lift up the ebonite sheet without touching the tray a second time. The tray is then found to be electrified. If a suspended gilt pitch ball is held near it, the ball will first be attracted and then repelled. If small fragments of paper are scattered on the tray and then the other tray held in the hand over them, they will fly up and down rapidly. If the knuckle is placed to the electrified tray, a small spark will be seen, and afterwards the tray will be found to be discharged or unelectrified. If the electrified tray is touched with the sealing-wax or ebonite rod, it will not be discharged, but if touched with a metal wire, the hand, or a damp thread, it is discharged at once. This shows that some bodies are conductors and others non-conductors or insulators of electricity, and that bodies can be electrified by friction and impart their electric charge to other bodies. A charged conductor supported on a non-conductor retains its charge. It is then said to be insulated.

**Experiment II.**—Arrange two tea-trays, each on dry tumblers as before. Rub the sheet of ebonite with flannel, lay it face downwards on one tray, touch that tray with the finger for a moment and lift up the ebonite sheet, rub it again, and lay it face downwards on the second tray and leave it there. Then take two suspended gilt pitch balls and touch them (a) both against one tray; they will be found to repel each other; (b) touch one against one tray and the other against the other tray, and they will be found to attract each other. This proves the existence of two kinds of electricity, called positive and negative.

---

ELECTROSTATICS

The first tea-tray is positively electrified, and the second negatively. If an insulated brass ball is touched against the first tray and then against the knob or plate of the electroscope, the gold leaves will diverge. If the ball is touched against the other tray, and then afterwards against the previously charged electroscope, the leaves will collapse. This shows that the two electrics neutralize each other's effect when imparted equally to the same conductor.

**Experiment III.**—Let one tray be insulated as before, and the electried sheet of ebonite held over it, but not allowed to touch the tray. If the ebonite is withdrawn without touching the tray, the latter will be found to be electrified. If with holding the ebonite sheet over the tray the latter is also touched with an insulated brass ball, then this ball when removed and tested with the electroscope will be found to be negatively electrified. The sign of the electrification imparted to the electroscope when so charged—that is, whether positive or negative—can be determined by rubbing the sealing-wax rod with flannel and the glass rod with silk, and approaching them gently to the electroscope one at a time. The sealing-wax so treated is electrified negatively or positively, and the glass with positive or vitreous electricity. Hence if the electrified sealing-wax rod makes the leaves collapse, the electrics is positive, but if the glass rod does the same, the electrics is negative. Again, if, whilst holding the electrified ebonite over the tray, we touch the latter for a moment and then withdraw the ebonite sheet, the tray will be found to be positively electrified. The electrified ebonite is said to act by 4 electrostatic induction on the tray, and create in it two induced charges, one positive and the other of negative electricity. The last goes to earth when the tray is touched, and the first remains when the tray is insulated and the ebonite withdrawn.

**Experiment IV.**—Place a tin canister on a warm tumbler and connect it by a wire with the gold-leaf electroscope. Charge positively a brass ball held on an ebonite stem, and introduce it, without touching, into the canister. The leaves of the electroscope will diverge with positive electricity. Withdraw the ball and the leaves will collapse. Replace the ball again and touch the outside of the canister; the leaves will collapse. If then the ball be withdrawn, the leaves will diverge a second time with negative electrification. If, before withdrawing the ball, after touching the outside of the canister for a moment the ball is touched against the inside of the canister, then on withdrawing it the ball and canister are found to be discharged. This experiment proves that when a charged body is introduced on an insulated conductor it causes an electrical separation to take place; electricity of opposite sign is drawn to the side nearest the inducing body, and that of like sign is repelled to the remote side, and these quantities are equal in amount.

**Seat of the Electric Charge.**—So far we have spoken of electric charge as if it resided on the conductors which are electrified. The work of Benjamin Franklin, Henry Cavendish, Michael Faraday and J. Clerk Maxwell demonstrated, however, that all electric charge or electrification of conductors consists simply in the establishment of a physical state in the surrounding insulator or dielectric, which state is variously called electric strain, electric displacement or electric polarization. Under the action of the same or identical electric forces the intensity of this state in various insulators is determined by a quality of them called their dielectric constant, specific inductive capacity or inductivity. In the next place we must notice that electrification is a measurable magnitude and in electrostatics is estimated in terms of a unit called the electrostatic unit of electric quantity. In the absolute C.G.S. system this unit quantity is defined as follows:—If we consider a very small electrified spherical conductor, experiment shows that it exerts a repulsive force upon another similar and similarly electrified body. Cavendish and C. A. Coulomb proved that this mechanical force varies inversely as the square of the distance between the centres of the spheres. The unit of mechanical force in the centimetre-gramme-second (C.G.S.) system of units is the dyne, which is approximately equal to 1/981 part of the weight of one gramme. A very small sphere is said then to possess a charge of one electrostatic unit of quantity, when it repels another similar and similarly electrified body with a force of one dyne, the centres being at a distance of one centimetre, provided that the spheres are in vacuo or immersed in some insulator, the dielectric constant of which is taken as unity. If the two small conducting spheres are placed with centres at a distance $d$ centimetres, and immersed in an insulator of dielectric constant $K$, and carry charges of $Q$ and $Q'$ electrostatic units respectively, measured as above described, then the mechanical force between them is equal to $KQ/Q'$ dynes. For constant charges and distances the mechanical force is inversely as the dielectric constant of the surrounding medium to be unity. To avoid unnecessary complications we shall assume this latter condition in all the following discussion, which is equivalent simply to assuming that all our electrical measurements are made in air or in vacuo.

Owing to the confusion introduced by the employment of the term force, Maxwell and other writers sometimes use the words electromotive intensity in place of electric force. The reader should, however, notice that what is generally called electric force is the analogue in electricity of the so-called acceleration of gravity in mechanics, whilst electrification or quantity of electricity is analogous to mass. If a mass of $M$ grammes be placed in the earth's field at a place where the acceleration of gravity has a value $g$ centimetres per second, then the mechanical force acting on it and pulling it downwards is $Mg$ dynes. In the same manner, if an electrified body carries a positive charge $Q$ electrostatic units and is placed in an electric field at a place where the electric force or electromotive intensity has a value $E$ units, it is urged in the direction of the electric force with a mechanical force equal to $QE$ dynes. We must, however, assume that the charge $Q$ is so small that it does not sensibly disturb the original electric field, and that the dielectric constant of the insulator is unity.

Faraday introduced the important and useful conception of lines and tubes of electric force. If we consider a very small conductor charged with a unit of positive electricity to be placed in an electric field, it will move or tend to move under the action of the electric force in a certain direction. The path described by it when removed from the action of gravity and all other physical forces is called a line of electric force. We may otherwise define it by saying that a line of electric force is a line so drawn in a field of electric force that its direction coincides at every point with the resultant electric force at that point. Any line drawn in an electric field be divided up into small elements of length. We can take the sum of all the products of the length of each element by the resolved part of the electric force in its direction. This sum, or integral, is called the "line integral of electric force" or the electromotive force (E.M.F.) along this line. In some cases the value of this electromotive force between two points or conductors is independent of the precise path selected, and it is then called the potential difference (P.D.) of the two points or conductors. We may define the term potential difference otherwise by saying that it is the work done in carrying a small conductor charged with one unit of electricity from one point to the other in a direction opposite to that in which it would move under the electric forces if left to itself.

**Electric Potential.**—Suppose then that we have a conductor charged with electricity, we may imagine its surface to be divided up into small unequal areas, each of which carries a unit charge of electricity. If we consider lines of electric force to be drawn from the boundaries of these areas, they will cut up the space round the conductor into tubular surfaces called tubes of electric force.
force, and each tube will spring from an area of the conductor carrying a unit electric charge. Hence the charge on the conductor can be measured by the number of unit electric tubes springing from it. In the next place we may consider the charged body to be surrounded by a number of closed surfaces, such that the potential difference between any point on one surface and the earth is the same. These surfaces are called "equipotential" or "level surfaces," and we may so locate them that the potential difference between two adjacent surfaces is one unit of potential; that is, it requires one absolute unit of work (erg) to move a small body charged with one unit of electricity from one surface to the next. These enclosing surfaces, therefore, cut up the space into shells of potential, and divide up the tubes of force into electric cells. The surface of a charged conductor is an equipotential surface, because when the electric charge is in equilibrium there is no tendency for electricity to move from one part to the other.

We arbitrarily call the potential of the earth zero, since all potential difference is relative and there is no absolute potential any more than absolute level. We call the difference of potential between a charged conductor and the earth the potential of the conductor. Hence when a body is charged positively its potential is raised above that of the earth, and when negatively it is lowered beneath that of the earth. Potential in a certain sense is to electricity as difference of level is to liquids or difference of temperature to heat. It must be noted, however, that potential is a mere mathematical concept, and has no objective existence like difference of level, nor is it capable for the production of physical changes in bodies, such as those which are brought about by rise of temperature, apart from any question of difference of temperature. There is, however, this similarity between them. Electricity tends to flow from places of high to places of low potential, water to flow down hills, and heat to move from places of high to places of low temperature. Returning to the case of the charged body with the space around it cut up into electric cells by the tubes of force and shells of potential, it is obvious that the number of these cells is represented by the product QV, where Q is the charge and V the potential of the body in electrostatic units. An electrified conductor is a store of energy, and from the definition of potential it is clear that the work done in increasing the charge q of a conductor whose potential is V by a small amount dq is σdq, and since this added charge increases in turn the potential, it is easy to prove that the work done in charging a conductor with Q units to a potential V units is σQV units of work. Accordingly the number of electric cells into which the space round is cut up is equal to twice the energy stored up, or each cell contains half a unit of energy. This harmonizes with the fact that the real seat of the energy of electricity is the dielectric or insulator surrounding the charged conductor.

We have next to notice three important facts in electrostatics and some consequences flowing therefrom.

(i) Electrical Equilibrium and Potential.—If there be any number of charged conductors in a field, the electrification on them being in equilibrium or at rest, the surface of each conductor is an equipotential surface. For since electricity tends to move between points or conductors at different potentials, if the electricity is at rest, then the potential must be everywhere the same. It follows from this that the electric force at the surface of the conductor has no component along the surface, in other words, the electric force at the bounding surface of the conductor and insulator is everywhere at right angles to it.

By the surface density of electrification on a conductor is meant the charge per unit of area, or the number of tubes of electric force which spring from unit area of its surface. Coulomb proved experimentally that the electric force just outside a conductor at any point is proportional to the electric density at that point. It can be shown that the resultant electric force normal to the surface at a point just outside a conductor is equal to σε, where σ is the surface density at that point. This is usually called Coulomb's Law.

(ii) Seat of Charge.—The charge on an electrified conductor is wholly on the surface, and there is no electric force in the interior of a closed electrified conducting surface which does not contain any other electrified bodies. Faraday proved this experimentally (see Experimental Researches, series xi. § 1173) by constructing a large chamber or box of paper covered with thin gold leaf. This was insulated and highly electrified. In the interior no trace of electric charge could be found when tested by electrosopes or other means. Cavendish proved it by enclosing a metal sphere in two hemispheres of thin metal held on insulating supports. If the sphere is charged and then the jacketing hemispheres fitted on it and removed, the sphere is found to be perfectly discharged. Numerous other demonstrations of this fact were given by Faraday. The thinnest possible spherical shell of metal, such as a sphere of insulator coated with gold leaf, behaves as a conductor for static charge just as if it were a sphere of solid metal. The fact that there is no electric force in the interior of such a closed electrified shell is one of the most certainly ascertained facts in the science of electrostatics, and it enables us to demonstrate at once that particles of electricity attract and repel each other with a force which is inversely as the square of their distance.

We may give in the first place an elementary proof of the converse proposition by the following simple lemma:

Lemma.—If particles of matter attract one another according to the law of the inverse square the attraction of all sections of a cone for a particle at the vertex is the same. Definition.—The solid angle subtended by any surface at a point is measured by the quotient of its apparent surface by the square of its distance from that point. Hence the total solid angle round any point is 4π. The solid angles subtended by all normal sections of a cone at the vertex are therefore equal, and since the attractions of these sections on a particle at the vertex are proportional to their distances from the vertex, they are numerically equal to one another and to the solid angle of the cone.

Let us then suppose a spherical shell O to be electrified. Select any point P in the interior and let a fine drawn through it sweep out a small double cone (see fig. 1). Each cone cuts out an area on the surface equally inclined to the cone axis. The electric density on the sphere being uniform, the quantities of electricity on these areas are proportional to the areas, and if the electric force varies inversely as the square of the distance, the forces exerted by these two surface charges at the point of question are proportional to the solid angle of the little cone. Hence the forces due to the two areas at opposite ends of the chord are equal and opposed.

Hence we see that if the whole surface of the sphere is divided into pairs of elements by cones described through any interior point, the resultant force at that point must consist of the sum of pairs of equal and opposite forces, and is therefore zero. For the proof of the converse proposition we must refer the reader to the Electrical Researches of the Hon. Henry Cavendish, p. 419, or to Maxwell's Treatise on Electricity and Magnetism, and ed., vol. i. p. 76, where Maxwell gives an elegant proof that if the force in the interior of a closed conductor is zero, the law of the force must be that of the inverse square of the distance. From this fact it follows that we can shield any conductor entirely from external influence by other charged conductors by enclosing it in a metal case. It is not even necessary that

3 Maxwell, Ibid. vol. i. § 742; also Electrical Researches of the Hon. Henry Cavendish, edited by J. Clerk Maxwell (Cambridge, 1879), p. 104.
4 Laplace (Mec. Cél. vol. i. ch. ii.) gave the first direct demonstration; no function of r except r itself can satisfy the condition that a uniform spherical shell exerts no force on a particle within it.
this envelope should be of solid metal; a cage made of fine metal wire gauze which permits objects in its interior to be seen will yet be a perfect electrical screen for them. Electroscopes and electrometers, therefore, standing within it, would be found to have bodies can be perfectly shielded from influence by enclosing them in cylinders of metal gauze.

Even if a charged and insulated conductor, such as an open canister or deep cup, is not perfectly closed, it will be found that a proof-plane consisting of a small disk of gilt paper carried at the end of a rod of gum-lac will not bring away any charge if applied to the deep inside portions. In fact it is curious to note how large an opening may be made in a vessel which will lead away all of the charge for all electrical purposes "a closed conductor." Maxwell (Elementary Treatise, &c., p. 15) ingeniously applied this fact to the insulation of conductors. If we desire to insulate a metal ball to make it hold a charge of electricity, it is usual to do so by attaching it to a handle or stem of glass or ebonite. In this case the electric charge exists at the point where the stem is attached, and there leakage by creeping takes place. If, however, we employ a hollow sphere and let the stem pass through a hole in the side larger than itself, and attach the end to the interior of the sphere, then leakage cannot take place.

Another corollary of the fact that there is no electric force in the interior of a charged conductor is that the potential in the interior is constant and equal to that at the surface. For the definition of potential it follows that the electric force in any direction at any point is measured by the space rate of change of potential in that direction or \( E = \frac{dV}{dz} \). Hence the force is zero the potential \( V \) must be constant. (iii) Association of Positive and Negative Electricity. - The third leading fact in electrostatics is that positive and negative electricity are always created in equal quantities, and that for every charge, say, of positive electricity on one conductor there must exist on some other bodies an equal total charge of negative electricity. Faraday expressed this fact by saying that no absolute electric charge could be given to matter. If we consider the charge of a conductor to be measured by the number of tubes of electric force which proceed from it, then, since each tube must end on some other conductor, the above statement is equivalent to saying that the charges at each end of a tube of electric force are equal.

The facts may, however, best be understood and demonstrated by considering an experiment due to Faraday, commonly called the ice-pail experiment, because he employed for it a pewter ice-pail (Exp. Res. vol. ii. p. 279, or Phil. Mag. 1843, 21). On the surface of a small electrically charged glass plate a small ice-pail was placed, having a loose lid. Let a metal ball be suspended by a silk thread, and the canister lid so fixed to the thread that when the lid is in place the ball hangs in the centre of the canister. Let the ball and lid be removed by the silk, and let a charge, say, of positive electricity (+Q) be given to the ball. Let the canister be touched with the finger to discharge it perfectly. Then let the ball be lowered into the canister. It will be found that as it does so the gold leaves of the electroscope diverge, but collapse again if the ball is withdrawn. If the ball is lowered until the lid is in place, the leaves take a steady deflection. Next let the canister be touched with the finger, the leaves collapse, but diverge again when the ball is withdrawn. A test will show that in this last case the canister is left negatively electricized. If before the ball is withdrawn, after touching the outside of the canister with the finger, the ball is tilted over to make it touch the inside of the canister, then on withdrawing it the canister and ball are found to be perfectly discharged. The explanation is as follows: the charge (+Q) of positive electricity on the ball creates by induction an equal charge (-Q) on the inside of the canister when placed in it, and repels to the exterior surface of the canister an equal charge (+Q). On touching the canister this last charge goes to earth. Hence when the ball is touched against the inside of the canister before withdrawing it a second time, the fact that the system is found subsequently to be completely discharged proves that the charge (+Q) on the inside of the canister must be exactly equal to the charge +Q on the ball, and also that the inducing action of the charge +Q on the ball created equal quantities of electricity of opposite sign, one drawn to the inside and the other repelled to the outside of the canister.

Electrical Capacity. - We must next consider the quality of a conductor called its electrical capacity. The potential of a conductor has already been defined as the mechanical work which must be done to bring up a very small body charged with a unit of positive electricity from the earth's surface or other boundary taken as the place of zero potential to the surface of this conductor in question. The mathematical expression for this potential can in some cases be calculated or predetermined.

Thus, consider a sphere uniformly charged with \( Q \) units of positive electricity. It is a function of the radius of the sphere that the thin spherical shell of matter which attracts according to the law of the inverse square acts on all external points as if it were concentrated at its centre. Hence a sphere having a charge \( Q \) repels a unit charge placed at a distance \( x \) from its centre with a force \( Q^2/4 \pi \) dynes, and therefore the work \( W \) in ergs expended in bringing the unit up to that point from an infinite distance is given by the integral

\[
W = \int e^2Qdx = Q^2/4\pi \quad (1).
\]

Hence the potential at the surface of the sphere, and therefore the potential of the sphere, is \( Q/\pi \), where \( R \) is the radius of the sphere in centimetres. The quantity of electricity which must be given to the sphere to raise it to unit potential is therefore \( R \) electrical capacity. The capacity of a conductor is defined as that energy which is required to raise its potential to unity, all other charged conductors being at an infinite distance. This capacity is then a function of the geometrical dimensions of the conductor, and can be mathematically determined in certain cases. Since the potential of a small charge of electricity \( dq \) at a distance \( r \) is equal to \( dq/r \), and since the potential of all parts of a conductor is the same in those cases in which the distribution of surface density of electricity is uniform or symmetrical with respect to some point or axis in the conductor, we can calculate the potential by simply summing up terms like \( eQ \). If \( ds \) is an element of surface, \( e \) the density of electricity on it, and \( r \) the distance from the symmetrical centre. The capacity is then obtained as the quotient of the whole charge by this potential. Thus the distribution of electricity on a sphere in free space must be uniform, and all parts of the charge are at an equal distance \( R \) from the centre. Accordingly the potential at the centre is \( Q/\pi R \). But this must be the potential of the sphere, since all parts are at the same potential \( V \). Since the capacity \( C \) is the ratio of charge to potential, the capacity of the sphere in free space is \( QV = Q/\pi R \), or is numerically the same as that on a conductor in centimetres.

We can thus easily calculate the capacity of a long thin wire like a telegraph wire far removed from the earth, as follows: Let \( 2r \) be the diameter of the wire, \( \ell \) its length, and \( e \) the uniform density of the wire. Consider a thin rod of length \( \ell \) of the wire of width \( dz \); the charge on it is equal to \( 2\pi e/2 \) units, and the potential \( V \) at a point on the axis at a distance \( x \) from the annulus due to this elementary charge is

\[
V = \int 2\pi e/2 \sqrt{\left(\alpha^2 + \beta^2\right) dx} = 4\pi e \int \frac{\log(1 + \gamma^2) - \log(1 - \gamma^2)}{\sqrt{\gamma^2 - 1}} \quad (2).
\]

If, then, \( r \) is small compared with \( l \), we have \( V = 4\pi e \log l/r \). But the charge is \( Q = 2\pi e \), and therefore the capacity of the thin wire is given by

\[
C = \frac{1}{2\pi e} \log l/r.
\]

A more difficult case is presented by the ellipsoid.\(^1\) We have first to determine the form in which electricity distributes itself on a conducting ellipsoid in free space. It must be such a distribution that the potential in the interior will be zero, since the electric force must be zero. Consider the well-known theorem in attractions that if a shell is made of conductive material whose bounding surfaces are \( b, a, c \), and \( d(a - d) \), (b + d), (c + d), (a - c), where the potential of such a shell at any internal point not on its surface constant, and that for an ellipsoid whose bounding ellipsoids are ellipsoids confocal with the ellipsoidal shell. Hence if we distribute electricity over an ellipsoid, so that its density is everywhere proportional to the thickness of a shell formed by describing round

\(^1\) The solution of the problem of determining the distribution on an ellipsoid of a fluid that flows inversely as the nth power of the distance was first given by George Green (see Ferrer's edition of Green's Collected Papers, p. 119, 1871).

\(^2\) See Thomson and Tait, Treatise on Natural Philosophy, § 519.
the ellipsoid a similar and slightly larger one, that distribution will be in equilibrium and will produce a constant potential throughout the interior. Thus if $\sigma$ is the surface density, $\delta$ the thickness of the shell at any point, and $\rho$ the assumed volume density of the matter of the shell, we have $\sigma = \Delta \rho \delta$. Then the quantity of electricity on any element of surface $dS$ is $\Delta \rho \delta dS$ times the mass of the corresponding element of the shell; and if $Q$ is the whole quantity of electricity on the ellipsoid, $Q = \Delta \rho \delta \Sigma dS$ or $\Delta \rho \delta$ times the whole mass of the shell. This mass is equal to $4 \pi \frac{a b c}{2}$; therefore $Q = \Delta \rho \delta \pi a b c$ and $\delta = Q / \pi a b c$, where $p$ is the length of the perpendicular line from the centre of the ellipsoid on the tangent plane. Hence,

$$e = \frac{Q}{4 \pi a b c}$$

(3).

Accordingly for a given ellipsoid the surface density of free distribution of electricity on it is everywhere proportional to the length of the perpendicular line from the centre on the tangent plane at that point. From this we can determine the capacity of the ellipsoid as follows: Let $p$ be the length of the perpendicular on the centre of the ellipsoid, whose equation is $x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$ to the tangent plane at $x, y, z$. Then it can be shown that $1/p^2 = x^2/a^2 + y^2/b^2 + z^2/c^2$ (see Frost’s Solid Geometry, p. 172). Hence the density $e$ is given by

$$e = \frac{Q}{4 \pi a b c} \sqrt{\left(\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2}\right)}$$

(4).

and the potential at the centre of the ellipsoid, and therefore its potential as a whole is given by the expression,

$$V = \frac{Q}{4 \pi a b c} \int_0^\infty \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2}\right) dz$$

(5).

Accordingly the capacity $C$ of the ellipsoid is given by the equation

$$C = \frac{1}{4 \pi a b c} \int_0^\infty \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2}\right) dz$$

(6).

It has been shown by Professor Chrystal that the above integral may also be presented in the form,

$$C = \frac{1}{4 \pi a b c} \int_0^\infty \frac{dV}{V}$$

(7).

The above expressions for the capacity of an ellipsoid of three unequal axes are in general elliptic integrals, but they can be evaluated for the reduced cases when the ellipsoid is one of revolution, and hence在于 the limit either takes the form of a long rod or of a circular disk.

Thus if the ellipsoid is one of revolution, and $ds$ is an element of arc which sweeps out the element of surface $dS$, we have

$$dS = 2 \pi y dz = 2 \pi \psi dz = \frac{2 \pi \psi dx}{\sqrt{1 - \epsilon^2}}$$

(8).

Hence, since $e = \frac{Q}{4 \pi a b c} \sqrt{1 - \epsilon^2}$, $dS = Q / \sqrt{1 - \epsilon^2} dx$. Accordingly the distribution of electricity is such that equal parallel slices of the ellipsoid of revolution taken normal to the axis of revolution carry equal charges on their curved surface.

The capacity $C$ of the ellipsoid of revolution is therefore given by the expression

$$C = \frac{1}{4 \pi a b c} \int_0^\infty \frac{dV}{\sqrt{1 - \epsilon^2}}$$

(9).

If the ellipsoid is one of revolution around the major axis $a$ (prolate) and of eccentricity $\epsilon$, then the above formula reduces to

$$C = \frac{1}{4 \pi a b} \int_0^\infty \frac{dV}{\sqrt{1 - \epsilon^2}}$$

(10).

The capacity $C_a = a \log_2 a / b$.

In each case we have $C = a / (4 \pi)$ when $\epsilon = 0$, and the ellipsoid thus becomes a sphere.

In the extreme case when $\epsilon = 1$, the prolate ellipsoid becomes a long thin rod, and then the capacity is given by

$$C_a = a \log_2 a / b$$

(11).

which is identical with the formula (2) already obtained. In the other extreme case the oblate spheroid becomes a circular disk when $\epsilon = 1$, and then the capacity $C_a = a / \pi$. This last result shows that the capacity of a thin disk is $2 \pi a / 1 - \pi / 4$ times that of a sphere of the same radius. Cavendish (Elec. Rev. p. 137 and 347) determined in 1773 experimentally that the capacity of a sphere was $2 \pi^2 / 1 - \pi / 4$ times that of a disk of the same radius, a truly remarkable result for that date.

Three other cases of practical interest present themselves, viz. the capacity of two concentric spheres, of two coaxial cylinders and of two parallel planes.

Consider the case of two concentric spheres, a solid one enclosed by a shell. Let $r_1$ be the radius of the inner sphere, $r_2$ the inside radius of the outer sphere, and $r_3$ outside radius of the outer spherical shell. Let a charge $+Q$ be given to the inner sphere. Then this produces a charge $Q$ on the inside of the spherical shell, and a charge $-Q$ on the outside of the shell. Hence the potential $V$ at the centre of the inner sphere is given by $V = Q / (r_1-r_2) + Q / r_3$. If the outer shell is connected to the earth, the charge $Q$ disappears, and we have the capacity $C$ of the inner sphere given by

$$C = \frac{1}{1/r_1 - 1/r_2} = \left(\frac{r_2 - r_1}{r_1 r_2}\right)$$

(12).

Such a pair of concentric spheres constitute a condenser (see LEVYDEN, etc.), and it is obvious that by making $r_2$ nearly equal to $r_1$, we may enormously increase the capacity of the inner sphere. Hence the name condenser.

The other case of importance is that of two coaxial cylinders. Let a solid circular sectioned cylinder of radius $r_1$ be enclosed in a coaxial tube of inner radius $R_1$. Then the inner cylinder is at potential $V_1$ and the outer one kept at potential $V_2$. The lines of electric force between the cylinders are radial. Hence the electric force $E$ in the interspace varies inversely as the distance from the axis. Accordingly the potential $V_1$ at any point in the interspace is given by

$$e = \frac{V_1 r_1}{R_1 - V_2} = \frac{A}{r_1}$$

(13).

Then $A$ is the distance of the point in the interspace from the axis, and $r_1$ is a constant. Hence $V_1 - V_2 = A - B$. Let us consider a length $l$ of the cylinder, the charge $Q$ on the inner cylinder is $Q = 2 \pi r_1 l$, where $l$ is the surface density, and by Coulomb’s law $E = 2 \pi l r_1$, where $E_1 = A / r_1$ is the force at the surface of the inner cylinder.

Accordingly $Q = 2 \pi r_1 l / A = l / 2$. Then if the outer cylinder be at zero potential the potential $V_1$ of the inner one is

$$V_1 = \log (r_1 / r_2)$$

and its capacity $C = l / 2 \log r_1 / r_2$.

This formula is important in connexion with the capacity of electric cables, which consist of a cylindrical conductor (a wire) enclosed in a conducting sheath. If the dielectric or separating insulator has a constant $K$, then the capacity becomes $K$ times as great.

The capacity of two parallel planes can be calculated at once if we neglect the distribution of the lines of force near the edges of the plates, and assume that the only field is the uniform field between the plates. Let $V_1$ and $V_2$ be the potentials of the plates, and let a charge $Q$ be given to one of them. If $S$ is the surface of each plate, and $d$ their distance, then the electric force $E$ in the space between them is $E = (V_1 - V_2) / d$. But if $e$ is the surface density, $E = e r_2$, and $E = e Q / S$. Hence we have

$$Q = 4 \pi Q / S$$

(14).

In this calculation we neglect altogether the fact that electric force distributed on curved lines exists outside the interspace between the plates, and these lines in fact extend from the back of one plate to that of the other. G. K. Kirchhoff (Gesammelte Abhandlungen, p. 112) has given a full expression for the capacity $C$ of two circular plates and radius $r$ placed at any distance $d$ apart in air from which the edge effect can be calculated. Kirchhoff’s expression is as follows:—

$$C = \pi r^2 / \sqrt{\pi d}$$

(15).

In the above formula $e$ is the base of the Napierian logarithms. The form on the right-hand side of the equation is the expression for the capacity, neglecting the curved edge distribution of electric force, and the other terms take into account, not only the uniform field between the plates, but also the non-uniform field around the edges and beyond the plates.

In practice we can avoid the difficulty due to irregular distribution of electric force at the edges of the plate by use of a guard plate as suggested by Lord Kelvin. If a large plate has a circular hole cut in it, and this is nearly filled up by a circular plate lying in the same plane, and if we place a large plate parallel to the first, the electric field between this second plate and the small circular plate is nearly uniform; and if $S$ is the area of the small plate and $d$ its distance from the opposite plate, its capacity may be calculated by the simple formula $C = S / \sqrt{4 \pi d}$. The outer larger plate in which the hole is cut is called the "guard plate," and must be kept at the same potential as the smaller inner or "trap-door plate." The same arrangement can be supplied to a pair of parallel conductors by placing metal plates on either side of a larger sheet of dielectric or insulator we can construct a condenser of relatively large capacity, and one made from a known material. A cylinder of glass bottle coated within and without for three parts of the way up with tinfoil.

1 See article "Electricity," Encyclopaedia Britannica (9th edition), vol. viii. p. 30. The reader is also referred to an article by Lord Kelvin (Reprint of Papers on Electrodynamics and Magnetism, p. 178), entitled "Determination of the Distribution of Electricity on a Circular Segment of a Plane, or on a Conducting Surface of the shell, any given Influence," where another equivalent expression is given for the capacity of an ellipsoid.

In the absolute determination of capacity we have to measure the ratio of the charge of a condenser to its plate potential difference. One of the best methods for doing this is to charge the condenser by the known voltage of a battery, and then discharge it through a galvanometer and repeat the process rapidly and successively. If a condenser of capacity \( C \) is charged to potential \( V \), and discharged \( n \) times per second through a galvanometer, then the unknown of intermittent discharges is equivalent to a current \( nCV \). Hence if the galvanometer is calibrated by a potentiometer (see Sec. 3), we can determine the value of this current in amperes, and knowing the value of \( n \) and \( V \) thus determine \( C \). Various forms of condensers have been devised for effecting this charge and discharge rapidly by J. J. Thomson, R. T. Glazebrook, J. A. Fleming and W. C. Clinton and others. One form consists of a tuning-dork electrically maintained in oscillation of known period, which closes an electric contact at every vibration and sets another electromagnet in operation, which reverses a switch and moves over one terminal of the condenser from a battery to a galvanometer contact. In another form, a revolving contact is used driven by an electric motor, which consists of an insulating disk having on its surface slips of metal and three wire brushes a, b, c (see fig. 2) pressing against them. The metal slips are so placed that, as the disk revolves, the middle brush, connected to one terminal of the condenser \( C \), alternately puts in conductive connexion with first one and then the other outside brush, which are joined respectively to the battery B and galvanometer G terminals. From the speed of this motor the number of commutations per second can be determined and a method is especially useful for the determinations of very small capacities of the order of 100 electrostatic units or so and upwards.

**Dielectric constant.**—Since all electric charge exists in a state of strain or polarization of the dielectric, it is evident that the physical state and chemical composition of the insulator must be of great importance in determining electrical phenomena. Cavendish and subsequently Faraday discovered this fact, and the latter gave the name "specific inductive capacity," or "dielectric constant," to that quality of an insulator which determines the charge taken by a conductor embedded in it when charged to a given potential. The simplest method of determining it numerically is, therefore, that adopted by Faraday.

1 It is an interesting fact that Cavendish measured capacity in "globular inches," using as his unit the capacity of a metal ball, 1 in. in diameter. Hence his multiplication of his values for capacities by 3.1416 relates them to the E.S. units in the C.G.S. system. See Elec. Ret. p. 347.

4 Faraday, *Experimental Researches on Electricity*, vol. i. § 1252. For a very complete set of tables of dielectric constants of solids, liquids and gases see A. Winkelnkamp, *Handbuch der Physik*, vol. iv. pp. 98-149 (Breslau, 1905); also see Landolt and Börnstein’s *Tables of Physical Constants* (Berlin, 1894).
He constructed two equal condensers, each consisting of a metal ball enclosed in a hollow metal sphere, and he provided also certain hemispherical shells of shellac, sulphur, glass, &c., which he could so place in one condenser between the ball and enclosing sphere that it formed a condenser with solid dielectric. He then determined the ratio of the capacities of the two condensers, one with air and the other with the solid dielectric. This gave the dielectric constant $K$ of the material. Taking the dielectric constant of air as unity he obtained the following values, for shellac $K = 2.0$, glass $K = 1.76$, and sulphur $K = 2.17$.

Since Faraday’s time, by improved methods, but depending essentially upon the same principles, an enormous number of determinations of the dielectric constants of various insulators, solid, liquid and gaseous, have been made (see tables I., II., III. and IV.). There are very considerable differences between the values assigned by different observers, sometimes no doubt due to differences in method, but in most cases unquestionably depending on variations in the quality of the specimens examined. The value of the dielectric constant is greatly affected by the temperature and the frequency of the applied electric force.

The above determinations at low temperatures were made with either a steady or a slowly alternating electric force applied a hundred times a second. They show that the dielectric constant of a liquid generally undergoes great reduction in value when the liquid is frozen and reduced to a low temperature.

The dielectric constants of gases have been determined by L. Boltzmann and I. Klemenčič as follows:

In general the dielectric constant is reduced with decrease of temperature towards a certain limiting value it would attain at the absolute zero. This variation, however, is not always linear. In some cases there is a very sudden drop at or below a certain temperature to a much lower value, and above and below the point the temperature variation is small. There is also a large difference in most cases between the value for a steadily applied electric force and a rapidly reversed or intermittent force—in the last case a decrease with increase of frequency. Maxwell (Proc. Roy. Soc. vol. ii. § 78) showed that the square root of the dielectric constant should be the same number as the refractive index for waves of the same frequency (see Electric Waves). There are very few substances, however, for which the optical refractive index has the same value as $K$ for steady or slowly varying electric force, on account of the great variation of the value of $K$ with frequency.

There is a close analogy between the variation of dielectric constant of an insulator with electric force frequency and that of the rigidity or stiffness of an elastic body with the frequency of applied mechanical stress. Thus pitch is a soft and yielding body under steady stress, but a bar of pitch if struck gives a musical note, which shows that it vibrates and is therefore stiff or elastic for high frequency stress.

### Residual Charges in Dielectrics.

In close connexion with this lies the phenomenon of residual charge in dielectrics. If a glass Leyden jar is charged and then discharged and allowed to stand awhile, a second discharge can be obtained from it, and in like manner a third, and so on. The reappearance of the residual charge is promoted by tapping the glass. It has been shown that this behaviour of dielectrics can be imitated by a mechanical model consisting of a series of perforated pistons placed in a tube of oil with spiral springs between each piston. If the pistons are depressed and then released, and then the upper piston fixed awhile, a second discharge can be obtained from it, and the mechanical stress-strain diagram of the model is closely similar to the discharge curve of a dielectric. R. H. A. Kohlrausch called attention to the close analogy between residual charge and the elastic recovery of strained bodies such as twisted wire or glass threads. If a charged condenser is suddenly discharged and then insulated, the reappearance of a potential difference between its coatings is analogous to the reappearance of a torque in the case of a glass fibre which has been twisted, released suddenly, and then gripped again at the ends.

For further information on the quality of dielectrics the reader is referred to the following sources:—J. Hopkinson, "On the Residual Charge of the Leyden Jar," Phil. Trans., 1876, 166 [i.], p. 489, where it is shown that tapping the glass of a Leyden jar permits the reappearance of the residual charge; "On the Residual Charge of Dielectrics," Proc. Roy. Soc., 1879, 38, p. 209;

the Leyden Jar,'* 8, 167 [ii.]. p. 599, containing many valuable observations on the residual charge of Leyden jars; W. E. Ayton and J. Ferry, A Preliminary Account of the Reduction of Observations on Strained Material, Leyden Jars and Voltameters Trans. Roy. Soc., 1880, 30, 411, showing experiments on residual charge of condensers and a comparison between the behaviour of dielectrics and glass-flux under torsion. In connection with this, the reader may also be referred to one by L. Boltzmann, "Zur Theorie der elastischen Nachwirkung," Wien. Acad. Sitz.-Ber., 1874, 70.

Distribution of Electric Charge:—We have no occasion to consider in more detail the laws which govern the distribution of electricity at rest upon conductors. It has been shown above that the potential due to a charge of g units placed on a very small sphere, compared with an equal charge at any distance from it is g/q.

The mathematical importance of this function called the potential is that it is a scalar quantity, and the potential at any point due to any number of point-charges q, g, q, . . . , distributed in any manner, is the sum of them separately, or

\[ \phi = q_1 / r_1 + q_2 / r_2 + q_3 / r_3 + \ldots = g/\varepsilon \]  

and similar expressions for the normal forces to the other pairs of faces dxdz, dydz, dxds. Hence, multiplying these normal forces by the areas of the corresponding faces, we have the total flux parallel to the normal to the x-axis given by \(-dV/dx\) dydz dxd and similar expressions for the other sides. Hence the total flux is

\[ -\left( \frac{dV}{dx} \frac{dV}{dy} \frac{dV}{dz} \right) = 0 \]  

This celebrated equation was first given by S. D. Poisson, although it is still generally attributed to Gauss. It defines the condition which must be fulfilled by the potential at any point in an electric field, through which x is finite and the electric force continuous. It may be looked upon as an equation of the field or of the potential, which exactly similar expression holds good in hydrodynamics, provided that for the electric potential we substitute velocity potential, and for the electric force we substitute velocity.

The Poisson equation cannot, however, be applied in the above form to a region which is partly within and partly without an enclosed conductor, because then the electric force undergoes a sudden change in value from zero to a finite value, in passing outwards through the bounding surface of the conductor. We can, however, obtain another equation called the "surface characteristic equation" as follows:—

\[ \frac{dV}{dS} + \frac{dV}{d\delta} + \frac{dV}{d\theta} = 0 \]  

and the potentials at points just outside and inside the surface dS, and let \( n_1 \) and \( n_2 \) be the normals to the surface drawn outwards and inwards; then \(-dV/dn_1\) and \(-dV/dn_2\) are the normal components of the force over the ends of the imaginary small cylinder. But the force perpendicular to the curved surface of this cylinder is everywhere zero. Hence the total flux through the surface due to the electric force and this by a previous theorem must be equal to \( 4\pi dS \), or the total included electric quantity. Hence we have the surface characteristic equation,

\[ \left( \frac{dV}{dS} + \frac{dV}{d\delta} + \frac{dV}{d\theta} \right) = 0 \]  

Let us apply this theorem to a portion of a tube of electric force. Let the part selected not increase any change in the field. Then the generating lines of the tube are lines of force, the component of the electric force perpendicular to the curved surface of the tube is everywhere zero. But the electric force is normal to the ends of the tube. Hence \( dS_0 \) and \( dS_0 \) are the areas of the ends, and \(+E\) and \(-E\) the oppositely directed electric forces at the ends of the tube, the surface integral of normal force on the flux over the tube is

\[ \mathbf{E} \cdot dS = E \cdot dS_0 \]  

and this by the theorem already given is equal to zero, since the tube includes no electricity. Hence the characteristic quality of a tube of electric force is that its section is everywhere inversely as the value of the field. To choose a section of this property, let any number of sources enclose the surface, the total flux per second through the surface is equal to the total strengths of all the sources. If, however, we defined the strength of the source by the statement that the strength divided by the square of the distance gives the value of the liquid at that point, then the total flux through any enclosing surface would be \( 4\pi \) times the strengths of all the sources enclosed. To every point-projection of some point source charge q at a distance r is defined to be \( q/\varepsilon \), and the total flux or induction through the sphere of radius r is therefore \( 4\pi q/\varepsilon \). If, however, the unit point charge charge was to be defined to be that produces a unit of electric flux through a circumscribing spherical surface or the electric force at distance r defined to be \( 1/\varepsilon r^2 \), many theories would be enunciated in simpler forms.

1 The beginner is often puzzled by the constant appearance of the following of the analytical tensors. It arises from the manner in which the unit quantity of electricity is defined. The electric force due to a point-charge q at a distance r is defined to be \( q/\varepsilon \), and the total flux or induction through the sphere of radius r is therefore \( 4\pi q/\varepsilon \). If, however, the unit point charge charge was to be defined to be that produces a unit of electric flux through a circumscribing spherical surface or the electric force at distance r defined to be \( 1/\varepsilon r^2 \), many theories would be enunciated in simpler forms.

2 See Maxwell, Electricity and Magnetism, vol. i. § 78b (2nd ed.).
3 Id. vol. i. § 80. Coulomb proved the proportionality of electric surface force to density, but the above numerical relation \( E = 4\pi \rho \) was first established by Poisson.
If we define the positive direction along a tube of electric force as the direction in which a small body charged with positive electricity would tend to move, we can summarize the above facts in a simple form by saying that, if we have any closed surface described in any manner in an electric field, the excess of the number of unit tubes which leave the surface over those which enter it is equal to 4π times the algebraic sum of all the electricity included within the surface.

ELECTROSTATICS

Method of Electrical Images.—A very powerful method of attacking problems in electrical distribution was first made known by Lord Kelvin, and is called the method of electrical images. By older mathematical methods it had only been possible to predict in a few simple cases the distribution of electricity at rest on conducting or insulating surfaces of various forms. The notion of an electrical image may be easily grasped by the following illustration: Let there be at (see fig. 5) a point-charge of positive electricity +q and an infinite conducting plate PO, shown in section, connected to earth and bearing a potential of zero.

Then the charge at A together with the induced surface charge on the plate makes a certain part of the edge of the plate PO, which is a zero equipotential surface. If we remove the plate, and yet by any means can keep the identical surface occupied by it and by the boundary conditions, the same field of force to the left of PO will remain unaltered. This can be done by placing at B an equal negative point-charge -q so that the total electric force between any two points in space is zero, as found by the optical image of A if PO were a mirror, that is, let -q be placed at B, so that the distance BO is equal to the distance OA and the potential of 0 at B in this ideal plane PO is equal to qAP/qBP+qO, while the resultant force at P due to the two point-charges is 2qAP/2qBP, and is parallel to AB or normal to PO. Hence if we remove the charge at B the total electric force in the surface PO is the same, and hence the potential at P is the same as in the case of the point-charge at A.

We can deduce a remarkable expression for the energy stored up in an electric field containing electrified bodies as follows: 1 Let V denote the potential at any point in the field. Consider the integral

$$W = \frac{1}{2} \iiint \left( \frac{dV}{dx} + \frac{dV}{dy} + \frac{dV}{dz} \right) ds \, dy \, dz \quad (21)$$

where the integration extends throughout the whole space unoccupied by conductors. We have by partial integration

$$\iiint \left( \frac{dV}{dx} + \frac{dV}{dy} + \frac{dV}{dz} \right) ds \, dy \, dz = \iiint \frac{dV}{dx} dy \, dz + \iiint \frac{dV}{dy} ds \, dx + \iiint \frac{dV}{dz} dx \, dy,$$

and two similar equations in y and z. Hence

$$\frac{1}{2} \iiint \left( \frac{dV}{dx} + \frac{dV}{dy} + \frac{dV}{dz} \right) ds \, dy \, dz = \iiint \nabla \cdot V \, ds \, dy \, dz \quad (22)$$

where $dV/\,ds$ means differentiation along the normal, and $\nabla$ stands for the operator $\frac{d}{dx} + \frac{d}{dy} + \frac{d}{dz}$. Let E be the resultant electric force at any point in the field. Then bearing in mind that $\epsilon = (1/4\pi) dV/\,ds$, and $\rho = -(1/4\pi) \nabla V$, we have finally

$$\frac{1}{2} \iiint \left( \nabla \cdot E + \nabla \cdot \rho \right) ds \, dy \, dz = \iiint V \, ds \, dy \, dz.$$

The first term on the right-hand side expresses the energy of the surface electrification of the conductors in the field, and the second the energy of the volume density (if any). Accordingly the term on the left hand side gives us the whole energy in the field.

Suppose that for some reason a conductor has a constant K, then we must multiply both sides by K and the expression for the energy per unit volume of the field is equivalent to $\epsilon \mathcal{E}$ where $\mathcal{E}$ is the displacement or potential due to the electricity.

Furthermore it can be shown by the application of the calculus of variations that the condition for a minimum value of the function $V$ is that $\nabla V = 0$. Hence that distribution of potential which is neces-

1 See Maxwell, Electricity and Magnetism, vol. 1, p. 99a (3rd ed., 1892), where the expression in question is deduced as a corollary of Green’s theorem.

Another equipotential surface is evidently a very small sphere described round A. The resultant force due to these two point-charges must then be in the direction CP, and its value E is the vector sum of the two forces along AP and BP due to the two point-charges. It is not difficult to show that

$$E = (\mathbf{A} \cdot \mathbf{r})/\epsilon \mathcal{E} \quad (25),$$

in other words, the force E is inversely as the cube of the distance from A. Suppose then we remove the negative point-charge, and let the sphere be supposed to become conductive and be connected to earth. If we make a distribution of negative electricity over it, which has a density $\epsilon \mathcal{E}$ according to the law

$$\rho = (\mathbf{A} \cdot \mathbf{r})^{2}/\epsilon \mathcal{E} \mathcal{P} \mathcal{A}^{2} \quad (26),$$

distribution, together with the point-charge +q at A, will make a distribution of electric force at all points outside the sphere

$^{1}$ See Lord Kelvin’s Papers on Electrostatics and Magnetism, p. 144.
ELECTROTHERAPEUTICS, a general term for the use of electricity in therapeutics, i.e. in the alleviation and cure of disease. Before the different forms of medical treatment are dealt with, a few points in connexion with the machines and currents, of special interest to the medical reader, must first be given.

Faradism. — For the battery required either for faradism or galvanism, cells of the Leclanché type are the most satisfactory. Being dry they can be carried in any position, are lighter, and there is no trouble from the erosion of wires and binding screws, such as so often results from wet cells. The best method of producing a smooth current in the secondary coil is for the interruptor hammer to vibrate directly against the iron core of the primary coil. For this it is best that the interruptor be made of a piece of steel spring, as a high rate of interruption can then be maintained, with a fairly smooth current in the secondary coil. This form of interruptor necessitates that the iron core be fixed, and variation in the primary induced current is arranged for by slipping a brass tube more or less over the iron core, thus cutting off the magnetic field from the primary coil. The secondary current (that obtained from the secondary coil) can be varied by keeping the secondary coil permanently fixed over the primary and varying the strength of the primary current. Where, as suggested above, the iron core is the primary and secondary induced currents will be at their strongest when the brass tube is completely withdrawn. As there is no simple means of measuring the strength of the faradic current, it is best to start with a very weak current, testing it on the muscles of one's own hand until these begin to contract and a definite sensory effect is produced; the current can then be applied to the part, being strengthened only very gradually.

Galvanism. — For treatment by galvanism a large battery is needed, the simplest form being known as a "patient's battery," consisting of a variable number of dry cells arranged in series. The cells used are those of Leclanché, with E.M.F. (or voltage) of 1.5 and an internal resistance of 3 ohms. Thus the exact strength of the current is known; the number of cells usually employed is 34, and when new give an E.M.F. of about 36 volts. By using the formula \( C = \frac{R}{U + V} \) where \( C \) is the voltage of the battery, \( R \) the total resistance of battery, electrodes and the patient's skin and tissues, and \( V \) the current in amperes, the number of cells required for any particular current can be worked out. The resistance of the patient's skin must be made as low as possible by thoroughly wetting both skin and electrodes with sodium bicarbonate solution, and keeping the electrodes in very close apposition to the skin. A galvanometer is always fitted to the battery, usually of the d'Arsonval type, with a shunt by means of which, on turning a screw, nine-tenths of the inducing current can be short-circuited away, and the solenoid only influenced by one-tenth of the current which is being used on the patient. In districts where electric power is available the continuous current can be used by means of a switchboard. A current of high electricity is used in the treatment of catarrhal congestion, by which is meant an alternating current whose curve of electromotive force, in both positive and negative phase, varies constantly and smoothly in what is known as the sine curve. In those districts supplied by an alternating current, the sinusoidal current can be obtained from the mains by passing it through various transformers, but where the main supply is the direct or constant current, a motor transformer is needed.

Static Electricity. — For treatment by static electricity the Wimshurst type of machine is the one most generally used. A number of electrodes are required; thus for the application of sparks a brass ball and brass roller electrode, for the "breeze" a single point and a multiple point electrode, and another multiple point electrode in the form of a metal cap that can be placed over the patient's head. The polarity of the machine must always be tested, as either knob may become positive or negative, though the polarity rarely changes when once the machine is in action. The oldest method of subjecting a patient to electric influence is that in which static electricity is employed. The patient is insulated on a suitable platform and treated by means of charges and discharges from an electrical machine. The effect is to increase the regularity and frequency of the pulse, raise the blood pressure and increase the action of the skin. The nervous system is quieted, sleep being promoted, the patient often becoming drowsy during the application. If while the patient is being treated a point electrode is brought towards him he feels the sensation of a wind blowing from that point; this is an electric breeze or brush discharge. The breeze is negative if the patient is positively charged and vice versa. The "breeze discharge" treatment is especially valuable in subduing pain of the superficial cutaneous nerves, and also in the treatment of chronic indolent ulcers. Quite recently this form of treatment has been applied with much success to various skin lesions—psoriasis, eczema and pruritus. Static electricity is also utilized for medical purposes by means of "sparks," which are administered with a ball electrode, the result being a sudden muscular contraction at the point of application. The electrode must be rapidly withdrawn before a second spark has time to leap across, as this is a severe form of treatment and must be administered slowly. It is mainly employed for muscular stimulation, and the contractions resulting from spark stimulation can be produced in cases of nerve injury and degeneration, even when the muscles are in a more or less flaccid state. The success of the treatment of this form of treatment is also strong, and is useful in hysterical anaesthesia and functional paralysis. Where a milder sensory stimulation is required friction can be used, the electrode being in the form of a metal roller which is moved rapidly outside the
patient's clothing over the spine or other part to be treated. The clothing must be dry and of wool, and each additional woolen layer intensifies the effect.

Another method of employing electricity at high potential is by the employment of high frequency currents. There are two methods of application: that in which brush discharges are made use of, with undoubtedly good effects in many of the diseases affecting the surface of the body, and that in which the currents of the solenoid are made to traverse the patient directly. The physiological value of the latter method is not certain, though one point of interest in connexion with it is that whereas stational applications raise the blood pressure, high frequency applications lower it. It has been used in the case of old people with arteriosclerosis, and the reduction of blood pressure produced is said to have shown considerable permanence.

The Faradic Current.—G. B. Duchenne was the first physician to make use of the induced current for treatment, and the term "faradisation" is supposed to be due to him. But in his day the differences between the two currents available, the primary and the secondary, were not worked out, and they were used somewhat indiscriminately. Nowadays it is generally accepted that the primary current should be used for the stimulation of deep-lying organs, as stomach and intestines, &c., while the secondary current is employed for stimulation of the limb muscles and the cutaneous sensory nerves. The faradic current is also used as a means of diagnosis of disease of the musculature. When the interrupted current is used to stimulate the skin over a motor nerve, all the muscles supplied by that nerve are thrown into rapid tetanic contraction, the contraction both beginning and ceasing sharply and suddenly with the current. This is the normal reaction of the nerve to faradism. If the muscle be wasted from disuse or some local cause unconnected with its nerve-supply, the contraction is smaller, and both arises and relaxes more slowly. But if the lesion lies in the nerve itself, as in Bell's palsy, the muscles no longer show any response when the nerve is stimulated, and this is known as the reaction of degeneration in the nerve. It is usually preceded by a condition of hyperexcitability. These results are applied to distinguish between functional paralysis and that due to some organic lesion, as in the former case the reaction of faradism will be as brisk as usual. Also at the beginning of most cases of infantile paralysis many more groups of muscles appear to be affected than ultimately prove to be, and faradism enables the physician to distinguish between those groups of muscles that are permanently paralysed owing to the destruction of their trophic centre, and those muscles which are only temporarily inhibited from action, and which with proper treatment will later regain their full power. In the testing of muscles electrically that point on the skin which on stimulation gives the maximum contraction for that muscle is known as the "motor point" for that muscle. It usually corresponds to the entry of the motor nerve.

Faradic treatment may be employed in the weakness and emaciation depending on any long illness, rickets, anaemia, &c. For these cases it is best to use the electric bath, the patient being placed in warm water, and the two electrodes, one at the patient's back and the other at his feet, being connected with the secondary coil. The patient's general metabolism is stimulated, he eats and sleeps better and soon begins to put on well for that.

This is especially beneficial in severe cases of rickets. In the weakness and emaciation due to neurasthenia, especially in those cases being treated by the Weir Mitchell method (isolation, absolute confinement to bed, massage and overfeeding), a similar faradic bath is a very helpful adjunct. In tabes dorsalis faradic treatment will often diminish the anaesthesia and numbness in the limbs, with resulting benefit to the ataxia. Perhaps the most beneficial use of the faradic current is in the treatment of chronic constipation—especially that so frequently met with in young women and due to deficient muscular power of the intestinal walls. In long-standing cases the large intestine becomes permanently dilated, and its muscular fibres so attenuated as to have no power over the intestinal contents. But faradism causes contraction at the point of stimulation, and the peristaltic wave thus started slowly progresses along the bowel. All that is needed is a special electrode for introduction into the bowel and an ordinary roller electrode. The rectal electrode consists of a 6-inch wire bearing at one end a small metal knob and fitted at the other into a metal cup which screws into the handle of the electrode. The only part exposed is the metallic knob; the rest is coated with some insulating material. The patient reclines on a couch on his back, the rectal electrode is connected, and having been vaselined is passed some three inches into the rectum. A current is started with the secondary coil in such a position as to give only an extremely weak current. The roller electrode is then wetted with hot water and applied to the front of the abdomen. At first the patient should feel nothing, but the current should slowly be increased until a faint response is perceptible from the abdominal muscles. This gives the required strength, and the roller electrode, pressed well into the abdominal wall, should very slowly be moved along the course of the large intestine beginning at the right iliac fossa. Thus a combination of massage and faradic current is obtained, and the results are particularly satisfactory. Treatment should be given on alternate days immediately after breakfast, and should be persevered with for six or eight weeks. The patient can be taught to administer it to himself.

The Galvanic, Continuous or Direct Current.—In using the galvanic or direct current the electrode must be covered with a layer of absorbent material to make contact with the skin. The electrode never being allowed to come in contact with the skin. The paddling by retaining moisture helps to make good contact, and also helps to guard against burning the skin. But when a continuous current of 3 am. or more is passed for more than 5 min. the electrodes must be raised periodically and the skin inspected. If the current be too strong or applied for too long a time, small blisters are raised which break and are very painful to the patient. Nor does the patient always feel much pain when this occurs. Also the electrodes must be remoistened every five or six minutes, as they soon become dry, and the skin will then be burnt. It is best to use a solution of sodium bicarbonate. Again, the danger of burning the skin depends on the density of the current per sq. in. of electrode, so that a strong current through a small electrode will burn the skin, whereas the same current through a larger electrode will produce a beneficial effect. If the patient be immersed up to his neck in an electric bath, much stronger currents can be passed without causing either pain or injury, as in this case the whole area of the skin in contact with the water acts as an electrode. In passing the current it must be remembered that the negative electrode or kathode is the more painful of the two, and its action more stimulating than the positive electrode or anode, which is sedative. If a muscle be stimulated over its motor point, it will contract with a sharp twitch and then become quiescent.

With normal muscle the KCC (kathodal closure contraction) is stronger than that produced by the closure of the current at the anode ACC (anodal closure contraction). And if the muscle be normal the opening contraction KOC and AOC are not seen. When a galvanic current is passed along a nerve its excitability is increased at the kathode and diminished at the anode. The increased excitability at the kathode is katelectrotonus, and the lowered excitability at the anode anelecrotonus. But since in a patient the electrode cannot be applied directly to the nerve, the lines of force from the electrode pass into the nerve both in an upward and downward direction, and hence there are two poles produced by each electrode. If the current be suddenly reversed, so that what was the anode becomes the kathode, a stronger contraction is obtained than by simply making and breaking the current. To avoid the four poles on the nerve to be tested, it is found most satisfactory to have one electrode placed at some distance, on the back or chest, not on the same limb.

As explained above, when the nerve supplying a muscle is diseased it no longer responds to the faradic current. On further testing this with the galvanic or continuous current it responds, but the contraction is not brisk but begins slowly and relaxes.
ELECTROTHERAPEUTICS

slowly, though the contraction as a whole may be larger than that of a normal muscle. This excessive contraction is known as hyperexcitability to galvanism. This form of contraction is that obtained when the muscle fibre itself is stimulated. Again, whereas in normal muscle KCC > ACC, when the nerve is degenerated KCC = ACC or ACC > KCC. Also in the more severe forms of nerve injury tetanic contractions may be set up in the paralysed muscles, by closure of the current either at the anode or cathode. These charges are known as the reaction of degenera-
tion and are of great value in diagnosis. They occur only after sudden or acute damage to the nerve cells of the anterior horn of the spinal cord, or to the motor nerve fibres proceeding from these cells. Thus RD is present in infantile paralysis, acute neuritis, &c., but absent in progressive muscular atrophy where the wasting of nerve and muscle takes place extremely slowly. The reaction of degeneration in the nerve is shown by disappearance of reaction to either kind of current, preceded for some days by hyperexcitability to either current. Where the muscle wasting is due to a lesion in the muscle alone, as in ischaemic myositis (usually due to injury from tight bandaging or badly applied splints), no reaction of degeneration is found; the only change is a loss of power in the contraction. If the damage to the anterior horn cells be only very slight, there may only be partial RD, and the prognosis is given according to the extent of RD. From this account it is clear that the greatest value of the continuous current lies in its use in diagnosis. But if a current is passed in a strictly local manner, the reaction is extremely sensitive to treatment by massage, to cases of infantile paralysis. Wrist drop from lead poisoning and lead neuritis of all kinds, reflex muscular atrophy and the muscular wasting of hemiplegia, are all benefited by the continuous current; the severe pain of sciatica, and the inflam-
mation of the nerve sheath in these cases, can be arrested more quickly by galvanic treatment than in any other way. Nearly all forms of neuritis, both of the cranial and other nerves, are best treated by the continuous current. The action in all cases is to stimulate the natural tendency to repair, very largely by improving the circulation through the injured parts.

Another effect of an electric current is electrolysis, and the phenomena of electrolytic conduction involve not merely the ionization of the compounds, but also the setting in motion of the ions towards their respective poles. Solutions which conduct electric currents are called electrolytes, and in the case of the human body the electrolyte is the whole mass of the saline con-
stituents in solution throughout the body. When a current is passed through an electrolyte, dissociation into ions takes place, the ions which are freed round the anode being called anions and those which are freed round the cathode being called cations. The anions carry negative charges and are consequently attracted by the positive electricity of the anode. The cations carry positive charges, hence they are repelled by the anode and attracted by the cathode. But a certain number of molecules do not dissociate, and hence in an electrolytic solution there are neutral molecules, anions and cations. The chemical actions, and thus the antiseptic, remedial or toxic effects of electrolytes, are due to the actions of their ions. The phosphates and phos-
phates may be taken as examples. Some are extremely toxic, while others are quite harmless. But it is to the phosphorus ion that the toxic or therapeutic effect is due. In the phosphates the phosphorus is part of a complex ion possessing quite different properties to those of the phosphorus ion of the phosphates. The strikingly different effects of the sulphates and sulphides are due to similar conditions, as also of many other compounds. There are certain solvents, as alcohol, chloroform, glycerin and vaseline which do not dissociate electrolytes, and consequently the latter become inert when mixed with these solvents. These solutions do not conduct electricity, and hence ionic effects are extremely slow. A vaseline ointment containing 5% of phenol makes a good dressing for an ulcer of the leg, and the local antiseptic effect is both caustic and toxic. Since the toxic or therapeutic action of a solution is due to its ions, the action must be proportional to the number of ions in a given volume, that is, the action of an
electrolyte depends on the degree of dissociation. Thus a strong acid is one that is much dissociated, a weak acid one that has undergone but little dissociation and so on. In 1896-1897 it was shown that the bactericidal action of salts varies with their degree of dissociation and therefore depends on the concentration of the active ions. In the medical application of these facts it must be remembered that when an ion is introduced into the body by electrolysis, it is probably forced into the actual cellular constituents of the body, whereas the drug administered by one of the usual methods though circulating in the blood may perhaps never gain access to the cell itself. Hence the different effects that have been recorded between a drug administered by the mouth or subcutaneously and the same administered by electro-
lysis. Thus a solution of cocaine injected subcutaneously pro-
duces quite different effects to that introduced by electrolysis. By the latter method it produces anaesthesia but does not diffuse, and the anaesthesia remains strictly limited to the surface covered by the electrode. It would appear that the ion is never intro-
duced into the general circulation but into the cell plasma.

In the technical working of medical electrolysis the most
minute precautions are required. The solution of the drug must be made with as pure water as possible, recently distilled. The spongy substance forming the electrode must be free from any trace of electrolytic substances. Hence all materials used must be washed in distilled water. Absorbent cotton answers all requirements and is easily procured. The area of introduction should be accurately cut in a circumscribed manner, in contact with the skin. Two layers of adhesive plaster which is applied to the skin and on which the electro-
lytic electrolytes are pressed. The great advantage of electrolytic methods is that it enables general treatment to be replaced by a strictly local treatment, and the cells can be saturated exactly to the degree and depth required. Strong antiseptics and materials that coagulate albumen cannot be introduced locally by ordinary methods, as the skin is impermeable to them, but by electrolysis they can be introduced to the exact depth required. The local effects of the ions depend on the dosage; thus a feeble dose of the ions of zinc stimulates the growth of hair, but a stronger dose produces the death of the tissue. Naturally the different ions produce different effects. Thus the ions of the alkalai and magnesium are caustic, those of the alkaline earthy metals produce actual mortification of the tissue and so on. According to the ion chosen the effect may be caustic in various degrees, antiseptic, coagulating, producing vascular or nervous changes, &c., &c. A blood electrosis is performed by extracting from the body such ions as are injurious, as uric and oxalic acid from a patient suffering from gout.

One of the latest advances is the treatment of ankylosed joints by the electrolytic method, the electrolyte used being chloride of sodium, and the marvellous results being attributed to the introduction of the chlorine ions. This sclerotic property of the current is applicable to all parts of the body accessible to the current. Old cases of rheumatic scleritis, entirely un-
affected by the routine treatment of salicylates and iodide, have often cleared up entirely under electrolytic treatment. Cases of chronic iritis with adhesions and old pleural adhesions are also suited for this method of procedure. Certain menstrual troubles of women and also endometritis yield rapidly to elec-
lysis with a zinc anode. Before this method of introduction, the zinc salts, though excellent disinfectants, acted only on the surface in consequence of their coagulating action on the albuminoids, but by the electric current, under the influence of a difference of potential, the zinc iron will penetrate to any desired depth. Cases of rodent ulcer unaffected by all other methods of treatment have been cured by electric kataphoresis with zinc ions, and the method is now being applied to the treatment of inoperable malignant tumours. As very strong currents are required for this latter, the patient has first to be anaesthetized by a general anaesthetic. Another direction in which electric ions are being used is that of the disinfection of cutting edges on sheets of minor surgical operations. Cocaine is the drug used, the resulting anaesthesia is absolute, and the operation can be made almost bloodless by the admixture of suprarenal extract.
ELEKTROTYPING, an application of the art of electroplating (q.v.) to typography (q.e.). In copying engraved plates for printing purposes, copper may be laid upon the original plate, the surface of which is first rendered slightly dirty, by means of a weak solution of wax in turpentine or otherwise, to prevent adhesion. The reversed plate thus produced is then stripped from the first and used as cathode in its turn, with the result that even the finest lines of the original are faithfully reproduced. The electrolyte commonly contains about 1 lb. of copper sulphate and ½ lb. of strong sulphuric acid per gallon, and is worked with a current density of about 10 ampères per sq. ft., which should give a thickness of c. 0.001 in. of copper per hour. As time is an object, the conditions alluded to in the article on COPPER as being favourable to the use of high current densities should be studied, bearing in mind that a tough copper deposit of high quality is essential. Moulds for reproducing plates or art-work are often taken in plaster, beeswax mixed with Venice turpentine, fusible metal, or gutta-percha, and the surface being rendered conductive by powdered black-lead, copper is deposited upon it evenly throughout. For statuary, and "undercast" work generally, an elastic mould—of glue and treacle (80:20 parts)—may be used; the mould, when set, is waterproofed by immersion in a solution of potassium bichromate followed by exposure to sunlight, or in some other way. The best results, however, are obtained by taking a wax cast from the elastic mould, and then from this a plaster mould, which may be waterproofed with wax, black-leaded, and used as a mould of this kind. In all of this work the possibility of being looked to in depositing are the electrical connexions to the cathode, the shape of the anode (to secure uniformity of deposition), the circulation of the electrolyte, and, in some cases, the means for escape of anode oxygen. Silver electrotyping is occasionally resorted to for special purposes.

ELECTRUM, ELECTRON (Gr. ἐλεκτρόν, amber), an alloy of gold and silver in use among the ancients, described by Pliny as containing one part of silver to four of gold. The term is also applied in mineralogy to native argentiferous gold containing from 20 to 50% of silver. In both cases the name is derived from the pale yellow colour of electrum, resembling that of amber.

ELIGIT (Lat. for "he has chosen"), in English law, a judicial writ of execution, given by the Statute of Westminster II. (1285), and so called from the words of the writ, that the plaintiff has chosen (eligat) this mode of satisfaction. Previously to the Statute of Westminster II., a judgment creditor could recover only the products of lands of a debt, but not the possession of the lands themselves. But this statute provided that henceforth it should be in the election of the party having recovered judgment to have a writ of fieri facias (q.e.) unto the sheriff on lands and goods or else all the chattels of the debtor and the one half of his lands until the judgment be satisfied. Since the Bankruptcy Act 1883 the writ of eligat has extended to lands and hereditaments only. (See further EXECUTION.)

ELEGY, a short poem of lamentation or regret, called forth by the decease of a beloved or revered person, or by a general sense of the pathos of mortality. The Greek word ἔλεγχις is of doubtful signification; it is usually interpreted as meaning a mournful or funeral song. But there seems to be no proof that this idea of regret for death entered into the original meaning of ἔλεγχις. The earliest Greek elegies which have come down to us are not funereal, although it is possible that the primitive ἔλεγχις may have been a set of words liturgically used, with music, at a burial. When the elegy appears in surviving Greek literature, we find it dedicated, not to death, but to war and love. Callinus of Ephesus, who flourished in the 7th century, is the earliest elegist of whom we possess fragments. A little later Tyrtaeus was composing his famous elegies in Sparta. Both of these writers were, so far as we know, exclusively war-like and patriotic. On the other hand, the passion of love inspires Milon of Pylos, and we see that his elegies are written in elegant later Greek pieces, and of the Latin poems of the school of Tibullus and Propertius, but of a great deal of the formal erotic poetry of modern Europe. In the 6th century B.C., the elegies of Solon were admired; they are merely lost. But we possess more of the work of Theognis of Megara than of any other archaic elegist, and in it we can observe the characteristics of Greek elegy best. Here the Dorian spirit of chivalry reaches its highest expression, and war is combined with manly love.

The elegy, in its calm movement, seems to have begun to lose currency when the ecstasy of emotion was more successfully interpreted by the various rhythmic and dithyrambic inventions of the Aeolic lyrist. The elegy, however, rose again to the highest level of merit in Alexander the Great's time. It was introduced by Philetas in the 3rd cent. B.C., and was carried to a fine perfection by Callimachus. Other later Greek elegists of high reputation were Asclepiades and Euphoron. But it is curious to notice that all the elegies of these poets were of an amatory nature, and that antiquity styled the funeral dirges of Thoecritus, Bion and Moschus—which are to us the types of elegy—not elegies at all, but idyls. When the poets of Rome began their imitative study of Alexandrian models, it was natural that the elegies of writers such as Callimachus should tempt them to immediate imitation. Gallus, whose works are unhappily lost, is known to have produced a great sensation in Rome by publishing his translation of the poems of Euphorion; and he passed on to the composition of erotic elegies of his own, which were the earliest in the Latin language. If we possessed his once-famous Cytheris, we should be able to decide the question of how much Propertius, who is now the leading figure among Roman elegists, owed to the example of Gallus. His magnificent emotional Cynthia, with its rich and unexampled employment of that alternation of hexameter and pentameter which had now come to be known as the elegiac measure, seems, however, to have settled the type of Latin elegy. Tibullus is always named in conjunction with Propertius, who was his contemporary, although in their style they were violently contrasted. The sweetness of Tibullus was the object of admiration and constant imitation by the Latin poets of Augustus. Although Propertius has more austerely pleased a later taste. Finally, Ovid wrote elegies of great variety in subject, but all in the same form, and his dexterous easy metre closed the tradition of elegiac poetry among the ancients. What remains in the decline of Latin literature is all founded on a study of those masters of the Golden Age.

When the Renaissance found its way to England, the word elegy was introduced by the Renaissance poets of Ovid and Propertius. But from the beginning of the 16th century elegy was composed, as it has been ever since, to describe a funeral song or lament. One of the earliest poems in English which bears the title of elegy is The Complaint of Philomene, which George Gascoigne began in 1562, and printed in 1576. The Dido nour of Spenser (1591) is an elegy in the strict modern sense, namely a poem of regret pronounced at the obsequies of a particular person. In 1579 Puttenham had defined an elegy as being a song "of long lamentation." With the opening of the 17th century the composition of elegies became universal on every occasion of public or private grief. Dr Johnson's definition, "Elegy, a short poem without points or turns," is singularly inept and careless. By that time (1755) English literature had produced many great elegies, of which the Lycidas of Milton is by far the most illustrious. But even Cowley's on Crashaw, Tickell's on Addison, Pope's on an Unfortunate Lady, those of Quarles, and Dryden, and Donne, should have warned Johnson of his mistake. Since then the 18th century has produced innumerable elegies in English literature, have been the Adonais of Shelley (on Keats), the Thyrus of Matthew Arnold (on Clough), and the Arc aegae Valer Swinburne (on Baudelaire). It remains for us to mention what is the most celebrated elegy in English, that written by Gray in a Country Churchyard. This, however, belongs to a class apart, as it is not addressed to the memory of any particular person. A writer of small merit, James Thomson (1710-1748), enjoyed a certain success with his Love of Elegies in which he endeavored to introduce the erotic elegy as it was written by Ovid and Tibullus. This experiment took no
hold of English literature, but was welcomed in France in the
amatory works of Parny (1753–1814), in those of Chénédolé
(1760–1835), and of Millevoye (1786–1816). The melancholy
and sentimental elegies of the last named are the typical examples
of this class of poetry in French literature. Lamartine must be
included among the elegists, and his famous "Le Lac" is as
eminent an elegy in French as Gray's "Country Churchyard"
is in English. The elegy has flourished in Portugal, partly
because it was cultivated with great success by Camoens, the
most illustrious of the Portuguese poets. In Italian, Chiabarrera
and Filicaia are named among the leading national elegists. In
German literature the notion of elegy is a part of the general
lyric form. The famous Roman Elegies of Goethe imitate
in form and theme those of Ovid; they are not even plaintive
in character.

ELEGIAIC VERSE has commonly been adopted by German
poets for their elegies, but by English poets never. Schiller
defines this kind of verse, which consists of a distich of which the
first line is a hexameter and the second a pentameter, in the
following pretty illustration:

"In the hexameter rises the fountain's silvery column,
and the springtime a melody back."

The word "elegy," in English, is one which is frequently
used very incorrectly; it should be remembered that it must be
mournful, meditative and short without being ejaculatory.
Thus Tennyson's In Memoriam is excluded by its
length; it may at best be treated as a collection of elegies.
Wordsworth's Lucy, on the other hand, is a dirge; this is too
brief a burst of emotion to be styled an elegy. Lycidas and
Adonais remain the two unapproachable types of what a personal
elegy ought to be in English.

(E. G.)

ELEMENT (Lat. elementum), an ultimate component of any-
thing, hence a fundamental principle. Elementum was used
in Latin to translate the Greek στοιχεῖον (that which stands
in στοιχεῖον, or row), and is a word of obscure origin and
etymology. The root of Lat. alere, to nourish, has been sug-
gested, thus making it a doublet of alimentum, that which sup-
ports life; another explanation is that the word represents
LMN, the first three letters of the second part of the alphabet,
parallel use to that of ABC. Apart from its application in
chemistry, which is treated below, the word is used of the
rudiments or principia of any science or subject, as in Euclid's
Elements of Geometry, or in the "beggarly elements" (άς τοι προτά
στοιχεία, of St Paul in Gal. iv. 9); in mathematics, of a funda-
mental concept involved in an invention, as the "elements" of
a determinant; and in electricity, of a galvanic (or voltaic)
"element" in an electric cell (see Electricity). It is used of a
"element" of the universe, or "element," used of any of the numerical
or geometrical data by which the course of a varying phenomenon is
computed; it is applied specially to orbital motion and eclipses.
The "elements of an orbit" are the six data by which the position
of a moving body in its orbit at any time may be determined.
The "elements of an eclipse" express and determine the motion
of the centre of the shadow-axis, and are the data necessary
to compute the phenomena of an eclipse during its whole course,
as seen at any place. In architecture the term "element"
is applied to the outline of the design of a Decorated window,
where the centres for the tracery are found. These centres
will all be found to fall on points which, in some way or other,
will be equidimensional parts of the openings.

Chemical Elements.

Like all other scientific concepts, that of an element has changed
its meaning many times in many ways during the
development of science. Owing to their very small
amount of real chemical knowledge, the generalizations
of the ancients were necessarily rather superficial,
and could not stand in the face of the increasing development
of practical chemistry. Nevertheless we find the concept of
an element as "a substance from which all bodies are made or
derived" held at the very beginning of occidental philosophy.
Thales regarded "water" as the element of all things; his
followers accepted his idea of a primordial substance as the basis
of all bodies, but they endeavoured to determine some other
general element or elements, like "fire" or "spirit," or "love"
and "hated," or "fire," or "water," or "air," or "earth." We
find in this development an exact parallelism to the manner
in which scientific ideas generally arise, develop and change.
They are created to point out the common part in a variety
of observed phenomena, in order to get some leading light in the
chaos of events. At first almost any idea will do, if only it
promises some comprehensive arrangement of the facts;
afterwards, the inconsistencies of the first trial make themselves
felt; the first idea is then changed to meet better the current
requirements. For a shorter or longer time the facts and ideas
may remain in accord, but the uninterupted increase of empirical
knowledge involves sooner or later new fundamental alterations
of the general idea, and in this way there is a never-ceasing
process of adaptation of the ideas to the facts. As facts are un-
changeable by themselves, the adaptation can be only one-sided;
the ideas are compelled to change according to the facts.
We must therefore educate ourselves to regard the ideas or theories
as the changing part of science, and keep ourselves ready to
accept even the most fundamental revision of current theories.
The first step in the development of the idea of elements was to
recognize that a single principle would not prove sufficient to
cover the manifoldness of facts. Empedocles therefore conceived
a double or binary elementary principle; and Aristotle developed
this idea a stage further, stating two sets of binary antagonistic
principles, namely "dry-wet" and "hot-cold." The Aristotelian
or peripatetic elements, which played such a great role in his
whole medieval philosophy, are the representatives of the several
binary combinations of these fundamental properties, "fire"
being hot and dry, "air" hot and wet, "water" cold and wet,
"earth" cold and dry. According to the amount of these prop-
erties found in any body, these elements were regarded as having
taken part in forming this body. Concerning the reason why
only these properties were regarded as fundamental, we know
nothing. They seem to be taken at random rather than carefully
selected; they relate only to the sense of touch, and not to vision
or any other sense, possibly because deceptions in the sense of
touch were regarded as non-existent, while the other senses were
apparently not so trustworthy. At any rate, the Aristotelian
elements soon proved to be rather inadequate to meet the
requirements of the increasing chemical knowledge; other
properties had therefore to be selected to represent the general
behaviour of chemical substances, and in this case we find them
already much more abundant in the middle ages.

Among the various substances recognized by the chemists,
certain classes or groups readily distinguished themselves.
First the metals, by their lustre, their heaviness, and
a number of other common properties. According to
the general principle of selecting a single substance
as a representative of the group, the metallic properties
were represented by "mercury." The theoreticians of the middle
ages were rather careful to point out that common mercury
(the liquid metal of to-day) was not at all to be identified with
"philosophical" mercury, the last being simply the principle
of metallic behaviour. In the same way combustibility was
represented by "sulphur," solubility by "salt," and occasionally
the chemically indifferent or refractory character by "earth."
According to the subsistence and preponderance of these prop-
erties in different bodies, these were regarded as containing
the corresponding elements; conversely, just as experiment teaches
the chemist every day that by proper treatment the properties
of given bodies may be changed in the most various ways, the
observed changes of properties were ascribed to the gain or loss
of the corresponding elements. According to this theory, which
accounted rather well for a large number of facts, there was no
fundamental objection against trying to endow base metals with
the properties of the precious ones; to make artificial gold was a
task quite similar to the modern problem of, e.g. making artificial
quartz. The realization that there is a certain natural law
preventing such changes is of much later date. It is therefore
quite unjust to consider the work of the alchemists, who tried

to make artificial gold, as consummate nonsense. *A priori* there

was no reason why a change from lead to gold should be less

possible than a change from iron to rust; indeed there is no a

priori reason against it now. But experience has taught us

that lead and gold are chemical elements in the modern sense,

and that there is a general experimental law that elements are

not transformable one into another. So experience taught the

alchemists irresistibly that in spite of the manifoldness of chemical

courses it is not always possible to change any given substance

into another; the possibilities are much more limited, and there

is only a certain range of substances to be obtained from a given

one. The impossibility of transforming lead or copper into noble

metals proved to be only one case out of many, and it was recog-
nized generally that there are certain chemical families whose

members are related to one another by their mutual transform-

ability, while it is impossible to bridge the boundaries separating

these families.

The man who brought all these experiences and considerations

into scientific form was Robert Boyle. He stated as a general

principle, that only tangible and ponderable substances

should be recognized as elements, an element being

a substance from which other substances may be made,

but which cannot be separated into different substances.

He showed that neither the peripatetic nor the alchemistic
elements satisfied this definition. But he was more of a critical

turn of mind than that with which he was endowed, and although he

was not in the correct principles, he hesitated to point out what substances,

among those known at his time, were to be considered as elements.

He only paved the way to the goal by laying the foundations of

analytical chemistry, *i.e.* by teaching how to characterize

to distinguish different chemical individuals. Further, by

adopting and developing the corpuscular hypothesis of the

constitution of the ponderable substances, he foreshadowed, in

a way, the law of the conservation of the elements, viz., that no

element can be changed into another element; and he considered

the compound substances to be made up from small particles

or corpuscles of their elements, the latter retaining their essence

in all combinations. This hypothesis accounts for the fact that

only a limited number of other substances can be made from a
given one,—namely, only those which contain the elements present

in the given substance. But it is characteristic of Boyle's critical

mind that he did not shut his eyes against a serious objection to this hypothesis. If the compound substance is made up of

parts of the elements, one would expect that the properties of

the compound substance would prove to be the sum of the

properties of the elements. But this is not the case, and chemical

compounds show properties which generally differ very consider-

ably from those of the compounds. On the one hand, the cor-

puscular hypothesis of Boyle was developed into the atomic

hypothesis of Dalton, which was considered at the beginning of the

19th century as the very best representation of chemical

facts, while, on the other hand, the difficulty as to the properties

of the compounds remained the same as Boyle found it, and has

not yet been removed by an appropriate development of the

atomic hypothesis. Thus Boyle considered, *e.g.* the metals as

elements. However, it is interesting to note that he considered

the mutual transformation of the metals as not altogether im-

possible, and he even tells of a case when gold was transformed

into base metal. It is a common psychological fact that a

reformer does not generally succeed in being wholly consistent

in his reforming ideas; there remains invariably some point

where he commits exactly the same fault which he set out to

abolish. We shall find the same inconsistency also among other

chemical reformers. Even earlier than Boyle, Joachim Jung

(1587–1657) of Hamburg developed similar ideas. But as he

did not distinguish himself, as Boyle did, by experimental

work in science, his views exerted only a limited influence amongst

his pupils.

In the times following Boyle's work we find no remarkable

outside development of the theory of elements, but a very

important inside one. Analytical chemistry, or the art of dis-

phlogostatian theory.

Work of Robert Boyle.

It was only after Isaac Newton's discovery of universal

gravitation that weight was considered as a property of para-

mount interest and importance, and that the question of the

changes of weight in chemical reactions became

Lavoisier's reform.

one worth asking. When in due time this question was

raised, the fact became evident at once, that combus-

tion means not loss but gain of weight. To be sure of this, it

was necessary to know first the chemical and physical properties

of gases, and it was just at the same time that this knowledge

was developed by Priestley, Scheele and others. Lavoisier was

the originator and expounder of the necessary reform. Oxygen

was just discovered at that time, and Lavoisier gathered evidence

from all sides that the theory of phlogiston had to be turned

inside out to fit the new facts.

He realized that the sum total of the weights of all sub-

stances concerned within a chemical change is not altered

by the change. This principle of the "conservation of weight"

led at once to a simple and unmistakable definition of a chemical

element. As the weight of a compound substance is the sum of

the weights of its elements, the compound necessarily weighs

more than any of its elements. An element is therefore a sub-

stance which, by being changed into another substance, in-

variably increases its weight, and never gives rise to substances

of less weight. By the help of this criterion Lavoisier composed

the first table of chemical elements similar to our modern ones.

According to the knowledge of his time he regarded the alkalis

as elements, although he remarked that they are rather similar

to certain oxides, and therefore may possibly contain oxygen;

the truth of this was proved at a later date by Humphry Davy.

But the inconsistency of the reformer, already referred to, may

be observed with Lavoisier. He included "heat and light" in

his list of elements, although he knew that neither of them had

weight, and that neither fitted his definition of an element; this

atavistic survival was subsequently removed from the table of

the elements by Berzelius in the beginning of the 19th century.

In this way the question of what substances are to be regarded

as chemical elements had to be considered in a quite different

way, but it is interesting to realize that the last step in this

development, the theory of Lavoisier, was based on quantitative

considerations. Such considerations became of paramount
interest at once, and led to the concept of the combining weights of the elements.

The first discoveries in this field were made in the last quarter of the 18th century by J. B. Richter. The point at issue was a rather commonplace one: it was the fact that when two neutral salt solutions were mixed to undergo mutual chemical decomposition and recombination, the resulting liquid was neutral again, i.e. it did not contain any excess of acid or base. In other words, if two salts, $A'B'$ and $A'B'$, composed of the acids $A'$ and $A'$ and the bases $B'$ and $B'$ undergo mutual decomposition, the amount of the base $B'$ left by the first salt, when its acid $A'$ united with the base $B'$ to form a new salt $A'B'$, was just enough to make a neutral salt $A'B'$ with the acid $A'$ left by the second salt. At first sight this looks quite simple and self-evident, - that neutral salts should form neutral ones again and not acid or basic ones, - but if this fact is once stated very serious quantitative inferences may be drawn from it, as Richter showed. For if the symbols $A'$, $A'$, $B'$, $B'$ denote at the same time such quantities of the acids and bases as form neutral salts, then if three of these quantities are determined, the fourth may be calculated from the others. This follows from the fact that by decomposing $A'B'$ with just the proper amount of the other salt to form $A'B'$, the remaining quantities $B'$ and $A'$ exist in exactly the ratio to form a neutral salt $A'B'$. It is possible, therefore, to ascribe to each acid and base a certain relative weight or "combining weight" by which they will combine with the other to form neutral salts. The same reasoning may be extended to any number of acids and bases.

It is true that Richter did not find out by himself this simplest statement of the law of neutrality which he discovered, but he expressed the same consequence in a rather clumsy way by a table of the combining weights of different bases related to the unit amount of a certain acid, and doing the same thing for the unit weight of every other acid. Then he observed that the numbers in these different tables are proportionate one to another. The numbers good if the corresponding series of the combining weights of acids for unit weights of different bases were tabulated. It was only a little later that a Berlin physicist, G. E. Fischer, united the whole system of Richter's numbers simply into a double table of acids and bases, taking as unit an arbitrarily chosen substance, namely sulphuric acid. The following table by Fischer is therefore the first table of combining weights.

</table>

It is interesting again to notice how difficult it is for the discoverer of a new truth to find out the most simple and complete statement of his discovery. It looks as if the amount of work needed to get to the top of a new idea is so great that not enough energy remains to clear the very last steps. It is noteworthy also to observe how difficult it was for the chemists of that time to understand the bearing of Richter's work. Although a summary of his results was published in Berthollet's Essai de staticque chimique, one of the most renowned chemical books of that time, nobody dared for a long time to take up the scientific treasure laid open for all the world.

At the beginning of the 19th century the same question was taken up from quite another standpoint. John Dalton, in his investigations of the behaviour of gases, and in order to understand more easily what happened when gases were absorbed by liquids, used the corpuscular hypothesis already mentioned in connexion with Boyle. While he depicted to himself how the corpuscles, or, as he preferred to call them, the "atoms" of the gases, entered the interior of the atoms of the liquids in which they dissolved, he asked himself: Are the several atoms of the same substance exactly alike, or are there differences as between the grains of sand? Now experience teaches us that it is impossible to separate, for example, a quantity of pure water into two samples of somewhat different properties. When a pure substance is fractionated by partial distillation or partial crystallization or partial change into another substance by chemical means, we find constantly that the residue is not changed in its properties, as it would be if the atoms were slightly different, since in that case e.g. the lighter atoms would distil first and leave behind the heavier ones, &c. Therefore we must conclude that all atoms of the same kind are exactly alike in shape and weight. But, if this be so, then all combinations between different atoms must proceed in certain invariable ratios of the weights of the elements, namely by the ratio of the weights of the atoms. Now it is impossible to weigh the atoms directly; but if we determine the ratio of the weights in which oxygen and hydrogen combine to form water, we determine in this way also the relative weight of their atoms. By a proper number of analyses of simple chemical compounds we may determine the ratios between the weights of all chemical elements, and, selecting one of them as a standard or unit, we may express the weight of all other atoms in terms of this unit. The following table is Dalton's (Mem. of the Lit. and Phil. Soc. of Manchester (II.), vol. 1. p. 287, 1803).

| Table of the Relative Weights of the Ultimate Particles of Gaseous and other Bodies. |
|---------------------------------|---------------------------------|---------------------------------|
| Hydrogen                        | Nitrous oxide                   | 13-7                           |
| Azot                            | Sulphur                        | 14-4                           |
| Carbon                          | Nitric acid                     | 15-2                           |
| Ammonia                         | Sulphuretted hydrogen          | 15-4                           |
| Ammonia                         | Carbonic acid                   | 15-2                           |
| Water                           | Alcohol                        | 15-1                           |
| Phosphorus                      | Sulphurous acid                 | 19-9                           |
| Sulphuric acid                  | Carbonate from sulphuric acid   | 25-4                           |
| Nitrous gas                     | Carbonate hydrogen from sulfuric acid | 9-3  |
| Ether                           | Manganese water                | 6-3                            |
| Gaseous oxide of carbon         | Olefiant water                 | 5-3                            |

Dalton at once drew a peculiar inference from this view. If two elements combine in different ratios, one must conclude that different numbers of atoms unite. There must be, therefore, a simple ratio between the quantities of the one element united to the same quantity of the other. Dalton showed at once that the analysis of carbon monoxide and of carbonic acid satisfied this consequence, the quantity of oxygen in the second compound being double the quantity in the first one. A similar relation holds good between marsh gas and olefiant gas (ethylene). This is the "law of multiple proportions" (see Atom). By these considerations Dalton extended the law of combining weights, which Richter had demonstrated only for neutral salts, to all possible chemical compounds. While the scope of the law was enormously extended, its experimental foundation was even smaller than with Richter. Dalton did not concern himself very much with the experimental verification of his ideas, and the first communication of his theory in a paper on the absorption of gases by liquids (1803) attracted as little notice as Richter's discoveries. Even when T. Thomson published Dalton's views in an appendix to his widely read text-book of chemistry, matters did not change very much. It was only by the work of J. J. Berzelius that the enormous importance of Dalton's views was brought to light.

Berzelius was at that time busy in developing a trustworthy system of chemical analysis, and for this purpose he investigated the composition of the most important salts. He then went over the work of Richter, and realized that by his law he could check the results of his analyses. He tried it and found the law to hold good in most cases; when it did not, according to his analyses, he found that the error was on his own side and that better analyses fitted Richter's law. Thus he was prepared to understand the importance of Dalton's views and he proceeded at once to test its exactness. The result was the best possible. The law of the combining weights of the
ELEMENT

atoms, or of the atomic weights, proved to hold good in every case in which it was tested. All chemical combinations between the several elements are therefore regulated by weight according to certain numbers, one for each element, and combinations between the elements occur only in ratios given by these weights or by simple multiples thereof. Consequently Berzelius regarded Dalton's atomic hypothesis as proved by experiment, and became a strong believer in it.

At the same time, T. H. Wollaston had discovered independently the law of multiple proportions in the case of neutral and acid salts. He gave up further work when he learned of Dalton's ideas, but afterwards he pointed out that it was necessary to distinguish the hypothetical part in Dalton's views from their empirical part. The latter is the law of combining weights, or the law that chemical combination occurs only according to certain numbers characteristic for each element. Besides this purely experimental law there is the hypothetical explanation by the assumption of the existence of atoms. As it is not proved that this explanation is the only one possible, the existence of the law is not a proof of the existence of the atoms. He therefore preferred to call the characteristic combining numbers of the elements not "atomic weights" but "chemical equivalents."

Although there were at all times chemists who shared Wollaston's cautious views, the atomic hypothesis found general acceptance because of its ready adaptability to the most diverse chemical facts. In our time it is even rather difficult to find...as Wollaston did, the empirical part from the hypothetical one, and the concept of the atom penetrates the whole system of chemistry, especially organic chemistry.

If we compare the work of Dalton with that of Richter we find a fundamental difference. Richter's inference as to the existence of combining weights in salts is based solely on an experimental observation, namely, the persistence of neutrality after double decomposition; Dalton's theory, on the contrary, is based on the hypothetical concept of the atom. Now, however favourably one may think of the probability of the existence of atoms, this existence is really not an observed fact, and it is necessary therefore to ask: Does there exist some general fact which may lead directly to the inference of the existence of combining weights of the elements, just as the persistence of neutrality leads to the same consequence as to acids and bases? The answer is in the affirmative, although it took a whole century before this question was put and answered. In a series of rather difficult papers (Zeits. f. Phys. Chem. since 1855, and Annalen der Naturphilosophie since 1902), Franz Wald (of Kladno, Bohemia) developed his investigations as to the genesis of this general law. Later, W. Ostwald (Faraday lecture, Trans. Chem. Soc., 1904) simplified Wald's reasoning and made it more evident.

The general fact upon which the necessary existence of combining weights of the elements may be based is the shifting character of the boundary between elements and compounds. It has already been pointed out that Lavoisier considered the alkalils and the alkaline earths as elements, because in his time they had not been decomposed. As long as the decomposition had not been effected, these compounds could be considered and treated like elements without mistake, their combining weight being the sum of the combining weights of their (subsequently discovered) elements. This means that compounds enter in reaction with other substances as a whole, just as elements do. In particular, if a compound AB combines with another substance (elementary or compound) C to form a ternary compound ABC, it enters this latter as a whole, leaving behind no residue of A or B. Inversely, if a ternary compound ABC be changed into a binary one AB by taking away the element C, there will not be found any excess of A or B, but both elements will exhibit just the same combining weight as in the ternary compound.

Experimentally this important fact was proved first by Berzelius, who showed that by oxidizing lead sulphide, PbS, to lead sulphate, PbSO₄, no excess either of sulphur or lead could be found after oxidation; the same held good with barium sulphite, BaSO₄, when converted into barium sulphate, BaSO₄.

On a much larger scale and with very great accuracy the inverse was proved half a century later by J. S. Stas, who reduced silver chloride, AgClO₄, silver bromate, AgBrO₃, and silver iodate, AgIₙO₂, to the corresponding binary compounds, AgCl, AgBr and AgI, and searched in the residue of the reaction for any excess of silver or halogen. As the tests for these substances are among the most sensitive in analytical chemistry, the general law underwent a very severe test indeed. But the result was as it should be found by Berzelius: no excess of one of the elements could be discovered. We may infer, therefore, generally that compounds enter exterior combinations without change of the ratio of their elements, or that the ratio between different elements in their compounds is the same in binary and ternary (or still more complicated) combinations.

This law involves the existence of general combining weights just in the same way as the law of neutrality with double decomposition of salts involves the law of the combining weights of acids and bases. For if the ratio between A and B is determined, this same ratio must obtain in all ternary and more complicated compounds, containing the same elements. The same is true for any other elements, C, D, E, F, &c., as related to A. But by applying the general law to the ternary compound ABC the same conclusion may be drawn as to the ratio A:C in all compounds containing A and C, or B:C in the corresponding compounds. By reasoning further in the same way, we come to the conclusion that the general law states that any such compound, which contains elements according to certain ratios, i.e., their combining weight. Any other ratio would violate the law of the integral reaction of compounds.

As to the law of multiple proportions, it may be deduced by a similar reasoning by considering the possible combinations between a compound, e.g., AB, and one of its elements, say B. AB and B can combine only according to their combining weights, and therefore the quantity of B combining with AB is equal to the quantity of AB which has combined with A to form AB. The new combination is therefore to be expressed by AB₁. By extending this reasoning in the same way, we get the general conclusion that any compounds must be composed according to the formula A_mBₙCₚ... where m, n, p, &c., are integers.

The bearing of these considerations on the atomic hypothesis is not to disprove it, but rather to show that the existence of the law of combining weights, which has been considered for so long as a proof of the truth of this hypothesis, does not necessarily involve such a consequence. Whether atoms may prove to exist or not, the law of combining weights is independent thereof.

Two problems arose from the discoveries of Dalton and Berzelius. The first was to determine as exactly as possible the correct numbers of the combining weights. The other was to find from the fact that the same elements may combine in different ratios. Which of these ratios gives the true ratio of the atomic weights? And which is the multiple one? Both questions have had most ample experimental investigation, and are now answered rather satisfactorily. The first question was a purely technical one; its answer depended upon analytical skill, and Berzelius in his time easily took the lead, his numbers being readily accepted on the continent of Europe. In England there was a certain hesitation at first, owing to Prout's assumption (see below), but when Turner, at the instigation of the British Association for the Advancement of Science, tested Berzelius's numbers and found them entirely in accordance with his own measurements, these numbers were universally accepted. But then a rather large error in one of Berzelius's numbers (for carbon) was discovered in 1841 by Dumas and Stas, and a kind of panic ensued.

New determinations of the atomic weights were undertaken in most countries. The result was not satisfactory: Berzelius, for no other important error was discovered, and even Dumas remarked that repeating a determination by Berzelius only meant getting the same result, if one worked properly. In later times more exact measurements, corresponding to the increasing art in analysis, were carried out by various workers, amongst...
whom J. S. Stas distinguished himself. But even the classical work of Stas proved not to be entirely without error; for every period has its limits of accuracy, which extends slowly as science extends. In recent times American chemists have been especially prominent in work of this kind, and the determinations of E. W. Morley, T. W. Richards and G. F. Baxter rank among the first in this line of investigation.

During this work the question arose naturally: How far does the exactness of the law extend? It is well known that most natural laws are only approximations, owing to disturbing causes that are associated with atomic weights. The answer is that as far as we know there are none. The law is still an exact one. But we must keep in mind that an absolute answer is never possible. Our exactness is in every case limited, and as long as the possible variations lie behind this limit, we cannot tell anything about them. In recent times H. Landolt has doubted and experimentally investigated the law of the conservation of weight.

Landolt's experiments were carried out in vessels of the shape of an inverted U, each branch holding one of the substances to react one on the other. Two vessels were prepared as equal as possible and hung on both sides of a most sensitive balance. Then the difference of weight was determined in the usual way by exchanging both the vessels on the balance. After this set of weighings one of the vessels was inverted and the chemical reaction between the contained substances was performed; then the double weighing was repeated. Finally also the second vessel was weighed and a third set of weighings taken. From blank experiments where the vessels were filled with substances which did not react one on the other, the maximum error was determined to 0.03 milligramme. The reactions experimented with were: silver salts with ferrous sulphate; iron on copper sulphate; gold chloride and ferrous chloride; iodic acid and hydriodic acid; iodine and sodium sulphite; uranyl nitrate and potassium hydrate; chlorate hydrate and potassium hydrate; electrolysis of caesium iodide by an alternating current; solution of ammonium chloride, potassium bromide and uranyl nitrate in water, and precipitation of an aqueous solution of copper sulphate by alcohol. In most of these experiments a slight diminution of weight was observed which exceeded the limit of error distinctly in two cases, viz. silver nitrate with ferrous sulphate and iodic acid with hydriodic acid, the loss of weight amounting from 0.080 to 0.190 mg. with the first and 0.047 to 0.177 mg. with the second reaction on about 50 g. of substance. Of these results some had been realized in independent experiments, Landolt felt certain that there was no error of observation involved. But when the vessels were covered inside with paraffin wax, no appreciable diminution of weight was observed.

These experiments apparently suggested a small decrease of weight as a consequence of chemical processes. On repeating them, however, and making allowance for the different amounts of water absorbed on the surface of the vessel at the beginning and end of the experiment, Landolt found in 1988 (Zetl. physik. Chem. 64, p. 581) that the variations in weight are equally positive and negative, and he concluded that there was no change in weight, at least to the extent of 1 part in 10,000,000.

There is still another question regarding the numerical values of the atomic weights, namely: Are there relations between the numbers belonging to the several elements? Richter had arranged his combining weights according to their magnitude, and endeavoured to prove that they form a certain mathematical series. He also explained the incompleteness of his series by assuming that certain acids or bases requisite to the filling up of the gaps in the series, were not yet known. He even had the satisfaction that in his time a new base was discovered, which fitted rather well into one of his gaps; but when it turned out afterwards that this new base was only calcium phosphate, this way of reasoning fell into discredit and was resumed only at a much later date.

To obtain a correct table of atomic weights the second question already mentioned, viz. how to select the correct value in the case of multiple proportions, had to be answered. Berzelius proceeded substantially on the look-out for means to distinguish the true atomic weights from their multiples or sub-multiples, but he could not find an unmistakable test. The whole question fell into a terrible disorder, until in the middle of the 19th century S. Cannizzaro showed that by taking together all partial evidences one could get a system of atomic weights consistent in itself and fitting the exigencies of chemical systematics. Then a startling discovery was made by the same method which Richter had tried in vain, by arranging all atomic weights in one series according to their numerical values.

The Periodic Law.—The history of this discovery is rather long. As early as 1817 J. W. Döbereiner of Jena drew attention to the fact that the combining weight of strontium lies midway between those of calcium and barium, and some years later he showed that such "triax" occurred in other cases too. L. Gmelin tried to apply this idea to all elements, but he realized early that in many cases more than three elements had to be grouped together. While Ernst Lenssen applied the idea of triads to the whole table of chemical elements, but without any important result, the other idea of grouping more than three elements into series according to their combining weights proved more successful. It was the concept of homologous series just developed in organic chemistry which influenced such considerations. First Max von Pettenkofer in 1850 and then J. B. A. Dumas in 1851 undertook to show that such a series of similar elements could be formed, having nearly constant differences between their combining weights. It is true that this idea in all its simplicity did not hold good extensively enough; so J. P. Cooke and Dumas tried more complicated types of numerical series, but only with a temporary success.

The idea of arranging all elements in a single series in the order of the magnitude of their combining weights, the gern of which is to be found already in J. B. Richter's work, appears first in some tables published by Lothar Meyer for his lectures. Independently, A. E. de Chancourtois in 1862, J. R. Newlands in 1863, and D. I. Mendeleéff in 1869, developed the same idea with the same result, namely, that it is possible to divide this series of all the elements into a certain number of very similar parts. In their papers, which appeared in the same year, 1869, Lothar Meyer and Mendeleéff gave to all these trials the shape now generally adopted. They succeeded in proving beyond all doubt that this series was of a periodic character, and could be cut into shorter pieces of similar construction. Here again gaps were present to be filled up by elements to be discovered, and Mendeleéff, who did this, predicted from the general regularity of his table the properties of such unknown elements. In this case fate was more kind than with Richter, and science had the satisfaction of seeing these predictions turn out to be true.

The following table contains this periodic arrangement of the elements according to their atomic weight. By cutting the whole series into pieces of eight elements (or more in several
cases) and arranging these one below another in the alternating way shown in the table, one finds similar elements placed in vertical series whose properties change gradually and with some regularity according to their place in the table. Not only the properties of the uncombined elements obey this rule, but almost all properties of similar compounds of the elements.

But upon closer investigation it must be confessed that these regularities can be called only rules and not laws. In the first line one would expect that the steps in the values of the atomic weights should be regular, but it is not so. There are even cases when it is necessary to invert the order of the atomic weights to satisfy the chemical necessities. Thus argon has a larger number than potassium, but must precede it to fit into its proper place. The same is true of tellurium and iodine. It looks as if the real elements were scattered somewhat haphazard on a regular table, or if some independent factor were at work to disturb an existing regularity. It may be that the new facts mentioned above will lead also to an explanation of these irregularities; at present we must recognize them and not try to explain them away. Such considerations have to be kept in mind especially in regard to the very numerous attempts to express the series of combining weights in a mathematical form.

In several cases rather surprising agreements were found, but never without exception. It looks as if some very important factor involving the whole matter remained unknown, and before this has been elucidated no satisfactory treatment of the matter is possible. It seems therefore premature to enter into the details of these speculations.

In recent times not only our belief in the absolute exactness of the law of the conservation of weight has been shaken, but also our belief in the law of the conservation of the elements. The wonderful substance radium, whose existence has made us devise quite a number of old and established views, seems to be a fulfilment of the old problem of the alchemists. It is true that by its help lead is not changed into gold, but radium not only changes itself into another element, helium (Ramsay), but seems also to cause other elements to change. Work in this line is of present day origin only and we do not know what new laws will be found to regulate these most unexpected reactions (see Radioactivity). But we realize once more that no law can be regarded as free from criticism and limitation; in the whole realm of exact sciences there is no such thing as the Absolute.

Another question regarding the values of atomic weights was raised very soon after their first establishment. From the somewhat inexact first determinations William Prout concluded that all atomic weights are multiples of the atomic weight of hydrogen, thus suggesting all other elements to be probably made up from condensed hydrogen. We have found his determinations not at all in accordance with this assumption, and strongly opposed the arbitrary rounding off of the numbers practised by the partisans of Prout's hypothesis. His hypothesis remained alive, although almost every chemist who did exact atomic weight determinations, especially Stas, contradicted it severely. Even in our time it seems to have followers, who hope that in some way the existing experimental differences may disappear. But one of the most important and best-known relations, that between hydrogen and oxygen, has not once been determined from simple ratios, but has been determined by a large number of different investigators and by different methods to be undoubtedly lower, namely, 1:15:87. Therefore, if Prout's hypothesis contain an element of truth, by the act of condensation of some simpler substance into the present chemical elements a change of weight also must have occurred, such that the weight of the element did not remain exactly the weight of the simpler substance which changed into it. We have already remarked that such phenomena are not yet known with certainty, but they cannot be regarded as utterly impossible.

It may here be mentioned that the internationality of science has shown itself active also in the question of atomic weights. These numbers undergo incessantly small variations because of new work done for their determination. To avoid the uncertainty arising from this inevitable state of affairs, an international committee was formed by the cooperation of the leading chemical societies all over the world, and an international table of the most probable values is issued every year. The following table is that for 1910:

In the long and manifold development of the concept of the element one idea has remained prominent from the very beginning down to our times: it is the idea of a prordial matter. Since the naive statement of Thales that all things come from water, chemists could never reconcile themselves to the fact of the conservation of the elements. By an experimental investigation which extended over five centuries and more, the impossibility of transmuting one element into another—for example, lead into gold—was demonstrated in the most extended way, and nevertheless this law has so little entered the consciousness of the chemists that it is seldom explicitly stated even in carefully written text-books. It is true, however, that the attempt to reduce the manifest differences in the actual chemical elements to one single prordial matter have never ceased, and the latest development of science seems to endorse such a view. It is therefore necessary to consider this question from a most general standpoint.

In physical science, the chemical elements may be compared with such concepts as mass, momentum, quantity of electricity, entropy and such like. While mass and entropy are determined univocally by a unit and a number, quantity of electricity is a unit, a number and a sign, for it can be positive as well as negative. Momentum has a unit, a number and a direction in space. Elements do not have a common unit as the former magnitudes, but every element has its own unit, and there is no transition from one to another. All these magnitudes underlie a law of conservation, but to a very different degree. While mass was
considered as absolutely invariable in the classical mechanics, the newer theories of the electrical constitution of matter make mass dependent on the velocity of the moving electron. Momentum also is not entirely conservative because it can be changed by light-pressure. Entropy is known as constantly increasing, remaining constant only in an ideal limiting case. With chemical elements we observe the same thing as with momentum; though till recently considered as conservative, there is now experimental evidence that they do not always show this character.

Generally the laws of the conservation of mass, weight and elements are expressed as the "law of the conservation of matter." But this lacks scientific exactness because the term "matter" is generally not defined exactly, and because only the above-named properties of ponderable objects do not change, while all other properties do to a greater or less extent. Considered in the most general way, we may define matter as a complex of gravitational, kinetic and chemical energies, which are found to cling together in the same space. Of these energies the capacity factors, namely, weight, mass and elements, are conservative as described, while the intensity factors, potential, velocity and affinity, may change in wide limits. To explain why we find these energies constantly combined one with another, we only have to think of a mass without gravity or a ponderable body without mass. The first could not remain on earth because every movement would carry it into infinite space, and the second would acquire infinite velocity by the slightest push and would also disappear at once. Therefore only such objects which have both mass and weight can be handled and can be objects of our knowledge. In the same way all other energies come to our knowledge only by being (at least temporarily) associated with this combination of mass and weight. This is the true meaning of the term "matter."

In this line of ideas matter appears not at all as a primary concept, but as a complex one; there is therefore no reason to consider matter as the last term of scientific analysis of chemical facts, and the idea of a primordial matter appears as a survival from the very first beginning of European natural philosophy. The most general concept science has developed to express the variety of experience is energy, and in terms of energy (combined with number, magnitudes, time and space) all observed and observable experiences are to be described. (W.O.)

**ELEMI**, an oleo-resin (Manilla elemi) obtained in the Philippine Islands, probably from *Canarium commune* (nat. ord. Burseraceae), which when fresh and of good quality is a pale yellow gum with a honey-like consistency, but which gradually hardens with age. It is soluble in alcohol and ether, and has a spicly taste with a smell like fennel. In the 17th and 18th centuries the term elemi usually denoted an oleo-resin (American or Brazilian elemi) obtained from the genus *Iscia* in Brazil, and still earlier it meant oriental or African elemi, derived from *Boswellia Freeara*, which flourishes in the neighbourhood of Cape Gardafui. The word, like the older term animi, appears to have been derived from *enharmon* (Gr. *harmon*), the name of a styrptic medicine said by Pliny to contain tears exuded by the olive tree of Arabia.

**ELEPHANT**, the designation of the two existing representatives of the *Proboscidae*, a sub-order of ungulate mammals, and also extended to include their more immediate extinct relatives. As the distinctive characteristics of the sub-order, and also of the single existing genus *Elephas*, are given in the article *PROBOSCIDAE*, it will suffice to point out how the two existing species are distinguished from one another.

The more specialized of the two species is the Indian or Asiatic elephant, *Elephas maximus*, specially characterized by the extreme complexity of the structure of its molar teeth, which are composed of a great number of tall and thin plates of enamel and dentine, with the intervals filled by cement (see *PROBOSCIDAE*, fig. 1). The average number of plates of the six successive molar teeth may be expressed by the "ridge-formula" 4, 6, 8, 12, 16, 24. The plates are compressed from before backwards, the anterior and posterior surfaces (as seen in the worn grinding face of the tooth) being nearly parallel. Ears of moderate size. Upper margin of the end of the proboscis developed into a distinct finger-like process, much longer than the lower margins, and the whole trunk uniformly tapering and smooth. Five nails on the fore-foot, and four (occasionally five) on the hind-foot.

The Asiatic elephant inhabits the forest-lands of India, Burma, the Malay Peninsula, Cochin China, Ceylon and Sumatra. Elephants from the last-named islands present some variations from those of the mainland, and have been separated under the names of *E. seyulonius* and *E. sumatranus*, but they are not more than local races, and the Ceylon animal, which is generally tuskless, may be the typical *E. maximus*, in which case the Indian "maximus indicus." The appearance of the Asiatic elephant is familiar to all. In the wild state it is pugnacious, associating in herds of ten, twenty or more individuals, and, though it may under certain circumstances become dangerous, it is generally inoffensive and even timid, fond of shade and solitude and the neighbourhood of water. The height of the male at the shoulder when full grown is usually from 8 to 10 ft., occasionally as much as 11, and possibly even more. The female is somewhat smaller.

The following epitome of the habits of the Asiatic elephants is extracted from *Great and Small Game of India and Tibet*, by R. Lydekker:—

"The structure of the teeth is sufficient to indicate that the food consists chiefly of grass, leaves, succulent shoots and fruits; and this has been found by observation to be actually the case. In this respect the Asiatic species differs very widely from its African relative, whose nutriment is largely composed of boughs and roots. Another difference between the two animals is to be found in the great intolerance of the direct rays of the sun displayed by the Asiatic species, which never voluntarily exposes itself to their influence. Consequently, during the hot season in Upper India, and at all times except during the rains in the more forested districts, elephants keep much to the denser parts of the forests. In Southern India they delight in hill-forest, where the undergrowth is largely formed of bamboo, the tender shoots of which form a favourite delicacy; but during the rains they venture out to feed on the open grassy tracts. Water is everywhere essential to their well-being; and no animals delight more thoroughly in a bath. Nor are they afraid to venture out of their depth, being excellent swimmers, and able, by means of their trunks, to breathe without difficulty when the entire body is submerged. The herds, which are led by females, appear in general to be family parties; and although commonly restricted to from thirty to fifty, may occasionally include as many as one hundred head. The old bulls are very generally solitary for a considerable portion of the year, but return to the herds during the pairing season. Some "rogue" elephants—gunda of the natives—remain, however, permanently separated from the rest of their kind. All such solitary bulls, as their cullumina name indicates, are of a spiteful disposition; and it appears that with the majority the induction to live apart is due to their partiality for cultivated crops, into which the more timid females are afraid to venture. 'Must' elephants are males in a condition of—probably sexual—excitement, when an abundant discharge of dark oily matter exudes from two pores in the forehead. In addition to various sounds produced at other times, an elephant when about to charge gives vent to a shrill loud 'trumpet'; and on such occasions rushes on its
adversary with its trunk safely rolled up out of danger, endeavouring either to pin him to the ground with its tusks (if a male tusker) or to trample him to death beneath its ponderous knees or feet."

Exact information in regard to the period of gestation of the female is still lacking, the length of the period being given from eighteen to twenty-two months by different authorities. The native idea, which may be true, is that the shorter period occurs in the case of female and the longer in that of male calves. In India elephants seldom breed in captivity, though they do so more frequently in Burma and Siam; the domesticated stock is therefore replenished by fresh captures. Occasionally two calves are produced at a birth, although the normal number is one. Calves suckle with their mouths and not with their trunks. Unlike the African species, the Indian elephant charges with its trunk curled up, and consequently in silence.

As regards their present distribution in India, elephants are found along the foot of the Himalaya as far west as the valley of Dehra-Dun, where the winter temperature falls to a comparatively low point. A favourite haunt used to be the swamp of Azughur, lying among the sal-forests to the northward of Meerut. In the great tract of forest between the Ganges and Kistna rivers they occur locally as far west as Bilsapur and Mandla; they are met with in the Western Ghats as far north as between latitude 17° and 18°, and are likewise found in the hill-forests of Mysore, as well as still farther south. In this part of the peninsula they ascend the hills to a considerable height, as they do in the Nawara Eliya district of Ceylon, where they have been encountered at an elevation of over 7000 ft. There is evidence that about three centuries ago elephants wandered in the forests of Malwa and Nimar, while they survived to a later date in the Chanda district of the Central Provinces. At the comparatively remote epoch when the Deccan was a forest tract, they were probably also met with there, but the swamps of the Bengal Sundarbans appear unsuited to their habits.

Of tusks, the three longest specimens on record respectively measure 8 ft. 9 in., 8 ft. 2 in. and 8 ft.; their respective weights being 81, 80 and 90 lb. These are, however, by no means the heaviest—one, whose length is 7 ft. 3½ in., weighing 102 lb; while a second, of which the length is 7 ft. 3 in., scaled 97½ lb. Of the largest pair in the possession of the British Museum, which belonged to an elephant killed in 1866 by Colonel G. M. Payne in Madras, one tusk measures 6 ft. 8 in. in length, and weighs 77½ lb, the other being somewhat smaller. It should be added that some of these large tusks came from Ceylon; such tuskers being believed to be descended from mainland animals imported into the island. "White" elephants are partial or complete albinos, and are far from uncommon in Burma and Siam. Young Indian elephants are hairy, thus showing affinity with the mammoth.

The African elephant is a very different animal from its Asiatic cousin, both as regards structure and habits; and were it not for the existence of intermediate extinct species, might well be regarded as the representative of a distinct genus. Among its characteristics the following points are noticeable. The molar teeth are of coarse construction, with fewer and larger plates and thicker enamel; the ridge-formula being 3, 6, 7, 7, 8, 10; while the plates are not flattened, but thicker in the middle than at the edges, so that their worn grinding-surfaces are lozenge-shaped. Ears very large. The upper and lower margins of the end of the trunk form two nearly equal prehensile lips. Only three toes on the hind-foot. A very important distinction is to be found in the conformation of the trunk, which, as shown in fig. 2, looks as though composed of a number of segments, gradually decreasing in size from base to tip like the joints of a telescope, instead of tapering gradually and evenly from one extremity to the other. The females have relatively large tusks, which are essential in obtaining their food. Except where exterminated by human agency (and this has been accomplished to a deplorable extent), the African elephant is a native of the wooded districts of the whole of Africa south of the Sahara. It is hunted chiefly for the sake of the ivory of its immense tusks, of which it yields the principal source of supply to the European market, and the desire to obtain which is rapidly leading to the extermination of the species. In size the male African elephant often surpasses the Asiatic species, reaching nearly 12 ft. in some cases. The circumference of the fore-foot is half the height at the shoulder, a circumstance which enables sportsmen to estimate approximately the size of their quarry. A tusk in the British Museum measures 10 ft. 2 in. in length, with a basal girth of 24 in. and a weight of 2264 lb.; but a still longer, although lighter, tusk was brought to London in 1905.

Several local races of African elephant have been described, mainly distinguished from one another by the form and size of the ears, shape of the head, &c. The most interesting of these is the pigmy Congo race, *E. africanus humilis*, named on the evidence of an immature specimen in the possession of C. Hagenbeck, the well-known animal-dealer of Hamburg, in 1903. According to Hagenbeck's estimate, this elephant, which came from the French Congo, was about six years old at the time it came under scientific notice. Moreover, in the opinion of the same observer, it is in nowise an abnormally dwarfed or ill-grown representative of the normal type of African elephant, but a well-developed adolescent animal. In height it stood about the same as a young individual of the ordinary African elephant when about a year and a half old, the vertical measurement at the shoulder being only 4 ft., or merely a foot higher than a new-born Indian elephant. Hagenbeck's estimate of its age was based on the presence of well-developed tusks, and the relative proportion of the fore and hind limbs, which are stated to be comparable in the young elephants of the same race as the adult elephant according to age. Nothing was stated as to the probability of an increase in the stature of the French Congo animal as it grows older; but even if we allow another foot, its height would be considerably less than half that of a large Central African bull of the ordinary elephant.

By Dr Paul Matschie several races of the African elephant have been described, mainly, as already mentioned, on certain differences in the shape of the ear. From the two West African races (*E. a. cyclotis* and *E. a. oxytis*) the dwarf Congo elephant is stated to be distinguished by the shape of its ear; comparison in at least one instance having been made with an immature animal. The relatively small size of the ear is one of the most distinctive characteristics of the dwarf race. Further, the skin is stated to be much less rough, with fewer cracks, while a more important difference occurs in the trunk, which lacks the transverse ridges so distinctive of the ordinary African elephant, and thereby approximates to the Asiatic species.

If the differences in stature and form are constant, there can be no question as to the right of the dwarf Congo elephant to rank as a well-marked local race; the only point for consideration being whether it should not be called a species. The great interest in connexion with a dwarf West African race of elephant is in relation to the fossil pigmy elephants of the limestone
fissures and caves of Malta and Cyprus. Although some of these elephants are believed not to have been larger than donkeys, the height of others may be estimated at from 4 to 5 ft., or practically the same as that of the dwarf Congo race. By their descriptors, the dwarf European elephants were regarded as distinct species, under the names of Elephas malensis, E. mnaodriensis and E. cyriprae; but since their molar teeth are essentially miniatures of those of the African elephant, it has been suggested by later observers that these animals are nothing more than dwarf races of the latter. This view may receive some support from the occurrence of a dwarf form of the African elephant in the Congo; and if we regard the latter as a subspecies of Elephas, it seems highly probable that the black position will have to be assigned to the pigmy European fossil elephants. If, on the other hand, the dwarf Congo elephant be regarded as a species, then the Maltese and Cyprian elephants may have to be classed as races of Elephas pumilio; or, rather, E. pumilio will have to rank as a race of the Maltese species. In this connexion it is of interest to note that, both in the Mediterranean islands and in West Africa, dwarf elephants of the African type accompanied by pigmy species of hippopotami although we have not yet evidence to show that in Africa the two animals occupy the same area. Still, the close relationship of the existing Liberian pigmy hippopotamus to the fossil Mediterranean species is significant, in relation to the foregoing observations on the elephant.

It may be added that fossil remains of the African elephant have been obtained from Spain, Sicily, Algeria and Egypt, in strata of the Pleistocene age. Some of the main differences in the habits of the African as distinct from those of the Asiatic elephant have been mentioned under the heading of the latter species. The most important of these are the greater tolerance by the African animal of sunlight, and the hard nature of its food, which consists chiefly of boughs and roots. The latter are dug up with the tusks; the left one being generally employed in this service, and thus becoming much more worn than its fellow.

**ELEPHANTA ISLE** (called by the natives Ghorapuri), a small island between Bombay and the mainland of India, situated about 6 m. from Bombay. It is nearly 5 m. in circumference, and the few inhabitants it contains are employed in the cultivation of rice, and in rearing sheep and poultry for the Bombay market. The island, till within recent times, was almost entirely overgrown with wood; it contains several springs of good water. There are also important quarries of building stone. But it owes its chief celebrity to the mythological excavations and shrines of Hindu superstition which occur at intervals along the whole coast. Opposite to the landing-place was a colossal statue of an elephant, cracked and mutilated, from which the island received from the Portuguese the name it still bears. The statue was removed in 1864, and may now be seen in the Victoria Gardens, Bombay. At a short distance from this spot is a cave, the entrance to which is nearly 60 ft. wide and 18 high, supported by pillars cut out of the rock; the sides are sculptured into numerous compartments, containing representations of the Hindu deities, but many of the figures have been defaced by the zeal of the Mahommedans and Portuguese. In the centre of the excavations is a remarkable Trimurti or bust, formerly thought to represent the Hindu Triad, namely, Brahma the Creator, Vishnu the Preserver, and Siva or Mahadeva the Destroyer, but now held to be a triform representation of Siva alone. The heads are from 4 to 5 ft. in length, and are well cut, and the faces, with the exception of the under lip, are handsome. The head-dresses are curiously ornamented; and one of the figures holds in its hand a cobra, while on the cap are, amongst other symbols, a human skull and an infant. On each side of the Trimurti is a pilaster, the front of which is filled up by a human figure leaning on a dwarf, both much defaced. There is a large compartment to the right, hollowed a little, and covered with a great variety of figures, the largest of which is 16 ft. high, representing the double figure of Siva and Parvati, named Viraj, half male and half female. On the right is Brahma.1 four-faced, on a lotus—one

of the very few representations of this god which now exist in India; and on the left is Vishnu. On the other side of the Trimurti is another compartment with various figures of Siva and Parvati, the most remarkable of which is Siva in his vindictive character, eight-handed, with a rollet of skulls round his neck. On the right of the entrance to the cave is a square apartment, supported by eight colossal figures, containing a gigantic symbol of Mahadeva or Siva cut out of the rock. In a ravine connected with the great cave are two other caves, also containing sculptures, which, however, have been much defaced owing to the action of damp and the falling of the rocks; and in another hill is a fourth cave. This interesting retreat of Hindu religious art is frequented by the Brahmans of Siva, but with the numerous representations of other Hindu deities. It has, however, for long been a place not so much of worship as of archaeological and artistic interest alike to the European and Hindu traveller. It forms a wonderful monument of antiquity, and must have been a work of incredible labour. Archaeological authorities are of opinion that the cave must have been excavated about the 10th century of the Christian era, if not earlier. The island is much frequented by the British residents of Bombay; and during his tour in India in 1875 King Edward VII, then prince of Wales, was entertained there at a banquet.

**ELEPHANTIASIS** (Barbadoes leg; Boucnemia), is a disease dependent on chronic lymphatic obstruction, and characterized by hypertrophy of the skin and subcutaneous tissue. Two distinct forms are known, (1) elephantiasis araba, due to the development of living parasites, filaria sanguinis hominis (or filaria Bancrofti), and (2) the non-filarial form due to lymphatic obstruction from any other cause whatsoever, as erysipelis, the deposit of tuberculous or cancerous material in the lymphatic glands, pleomiasias dolens (white leg), long-continued eczema, &c. The enlargement is limited to a particular part of the body, generally one, or in rare cases both of the lower limbs, occasionally the scrotum, one of the labia or the mammary gland; far more rarely the face. An attack is usually ushered in by febrile disturbance (elephantoid fever), the part attacked becoming rapidly swollen, and the skin tense and red as in erysipelis. The subcutaneous tissues become firm, infiltrated and hard, pitting only on considerable pressure. The skin becomes roughened with a network of dilated lymphatics, and vesicles and bullae may form, discharging a chyle-like fluid when broken (lymphorrhoea). In a later stage still the skin may be coarse and wart-like, and there is a great tendency for varicose ulcers to form. At the end of a variable time enlargement ceases to take place, and the disease enters a quiescent state; but recurrence of the intervals of enlargement still continues. In some cases the affected part remains permanently swollen. The only difference in the history of the two forms of the disease lies in the fact that the non-filarial form progresses steadily, until either the underlying condition is cured, or in the case of cancer, &c., brings about a fatal issue. The elephantiasis due to filaria is spread by the agency of mosquitoes, in whose bodies the intermediate stage is passed. The dead mosquito falls upon the water, which thus becomes infected, and hence the ova reach the human stomach. The young worm develops, bores through the gastric mucous membrane and finally becomes lodged in the lymphatics, usually of one or other of the extremities. A large number of embryonic filariae are produced. Some remain in the lymphatic spaces and cause lymphatic obstruction, while others enter the blood stream by night (filaria nocturna), or by day (filaria diurna). It is supposed that a mosquito, biting an infected person, may itself become infected with these blood it abstracts, and that so a new generation is developed.

Treatment for this condition is unsatisfactory. Occasionally the dilated lymph trunks can be found, and an operation performed to implant them in some vein (lymphangeoplasty). And in some few other cases artificial lymphatics have been made by introducing sterilized silk thread in the subcutaneous tissues of the affected part, and prolonging it into the normal tissues. This operation has been most successful when performed on
elephantoid arms dependent on a late stage of cancerous breast. Elevation of the limb and elastic pressure should always be tried, but often amputation has to be resorted to in the end. The disease is totally different from the so-called elephantiasis gracorum or true leprosy, for which see Leprosy.

**ELEPHANT’S-FOOT**, the popular name for the plant *Testudinaria elephantipes*, a native of the Cape of Good Hope. It takes its name from the large tuberous stem, which grows very slowly but often reaches a considerable size, *e.g.* more than 3 yds. in circumference with a height of nearly 3 ft. above ground. It is rich in starch, whence the name Hottentot bread, and is covered on the outside with thick, hard, corky plates. It develops slender, leafy, climbing shoots which die down each season. It is a member of the monocotyledonous order Dioscoreaceae, half of the 17th century, when it became a centre for the trade with south Russia.

**ELEUSIS**, an ancient Greek city in Attica about 14 m. N.W. of Athens, occupying the eastern part of a rocky ridge close to the shore opposite the island of Salamis. Its fame is due chiefly to its Mysteries, for which see MYSTERY. Tradition carries back the origin of Eleusis to the highest antiquity. In the earlier period of its history it seems to have been an independent rival of Athens, and it was afterwards reckoned one of the twelve Old Attic cities. A considerable portion of its small territory was occupied by the plains of Thria, noticeable for their fertility, though the hopes of the husbandmen were not unfrequently disappointed by the blight of the south wind. To the west was the *Pélagos* or Rharian Plain, where Demeter is said to

climbing plants with slender herbaceous or shrubby shoots, to which belong the yam and the British black bromy, *Tamus communis*.

**ELETS**, a town of Russia, in the government of Orel, 122 m. by rail E.S.E. of Orel, on the railway which connects Riga with Tsarsitsyn on the lower Volga. Pop. (1883) 36,680; (1900) 38,239. Owing to its advantageous position Elets has grown rapidly. Its merchants buy large quantities of grain, and numerous flour-mills, many of them driven by steam, prepare flour, which is forwarded to Moscow and Riga. The trade in cattle is very important. Elets has the first grain elevator erected in Russia (1887), a railway school, and important tanneries, foundries for cast iron and copper, tallow-melting works, limekilns and brickworks. The cathedral and two monasteries contain venerated historic relics.

Elets is first mentioned in 1147, when it was a fort of Ryazan. The Turkish Polovtsi or Kumans attacked it in the 12th century, and the Mongols destroyed it during their first invasion (1290) and again in 1305. The Tatars plundered it in 1415 and 1450; and it seems to have been completely abandoned in the latter half of the 15th century. Its development dates from the second...
Roman pavement, the curb surrounding an early well. This is almost certainly the ἐλευθεριον φωτις mentioned by Pausanias. The Great Propylaea is a structure of Roman imperial date, in close imitation of the Propylaea on the Athenian Acropolis. It is, however, set in a wall of 6th-century work, though repaired in later times. This wall encloses a sort of outer court, of irregular triangular shape. The Small Propylaea is not set exactly opposite to the Great Propylaea, but at an angle to it; an inscription on the architrave records that it was built by Appius Claudius Pulcher, the contemporary of Cicero. It is also set in a later wall that occupies approximately the same position as two smaller walls placed in Roman times. This was probably the temple. From the Small Propylaea a paved road of Roman date leads to one of the doors of the Telestern. Above the Small Propylaea, partly set beneath the overhanging rock, is the precinct of Pluto; it has a curious natural cleft approached by rock-cut steps. Several inscriptions and other antiquities were found here, including the famous head, now in Athens, usually called Eubouleus, though the evidence for its identification is far from satisfactory. A little farther on is a rock-cut platform, with a wall, approached by a broad flight of steps, which probably served for spectators of the sacred procession. Beyond this, close to the side of the Telestern, are the foundations of a temple on higher ground; it has been conjectured that this was the temple of Demeter, but there is no evidence that such a building existed in historic times, apart from the Telestern. The Telestern, or House of Initiation, was a large covered building, about 167 ft. square. It was surrounded on all sides by steps, which must have served as seats for the mystae, while the sacred dramas and processions took place on the floor of the hall; these seats were partly built up, partly cut in the solid rock; in later times they appear to have been cased with marble. There were two doors on each side of the hall, except the north-west, where it is cut out of the solid rock, and a rock terrace at a higher level adjoins it; this terrace may have been the station of those who were not yet admitted to the full initiation. The roof of the hall was carried by rows of columns, which were more than once renewed. The architectural history of the hall has been traced by Professor W. Dörpfeld with the help of the various foundations that have been brought to light. The earliest building on the site is a small rectangular structure, with walls of polygonal masonry, built of the rock quarried on the spot. This was succeeded by a square hall, almost of the same plan as the later Telestern, but about a quarter of the size; its eastern corner coincided with that of the later building, and it appears to have had a portico in front like that which, in the later hall, was a later addition. Its roof was carried by columns, of which the bases can still be seen. This building has with great probability been assigned to the time of Peisistratus; it was destroyed by the Persians. Between this event and the erection of the present hall, which must be substantially the one designed by Ictinus in the time of Pericles, there must have been a restoration, of which we may see the remains in a set of round sinkings to carry columns, which occur only in the north-east part of the hall; a set of bases arranged on a different system occur in the south-west part, and it is difficult to see how these two systems could be reconciled unless there were some sort of partition between the two parts of the hall. Both sets were removed to make way for the later columns, of which the bases and some of the drums still remain. These later columns are shown, by inscriptions and other fragments built into them, to be of later Roman date. The southern corners of the hall of Ictinus are projecting masses of masonry, which may be the foundation for a portico that was to be added; but perhaps they were only buttresses, intended to resist the thrust of the roof of this huge structure, which rested at its northern and western corners against the solid rock of the hill. On the south-east side the hall is faced with a portico, extending its whole width; the marble pavement of this portico is a most conspicuous feature of Eleusis at the present day. The portico was added to the hall by the architect Philo, under Demetrius of Phalerum, about the end of the 4th century B.C. It was never completed, for the fluting of its columns still remains unfinished.

The Telestern took up the greater part of the sacred precinct, which seems merely to have served to keep the profane away from the temple. The massive walls and towers of the time of Pericles, which resemble those of a fortress, are quite close in on the south and east; later, probably in the 4th century B.C., the precinct was extended farther to the south, and at its end was erected a building of considerable extent, including a curious apsidal chamber, for which a similar but larger curved structure was found in Italy. This was probably the Telestern. The precinct was full of altars, dedications and inscriptions; and many fragments of sculptures, pottery and other antiquities, from the earliest to the latest days of Greece, have been discovered. It is to be noted that the subterranean passages which some earlier explorers imagined to be connected with the celebration of the mysteries, have proved to be nothing but cisterns or watercourses.

The excavations of Eleusis, and the antiquities found in them, have been published from time to time in the Βουλήτης Αρχαιολογικός and in the Παραγωγή of the Greek Archaeological Society, especially for 1897 and 1899. See also D. Philos, Eleusis, ses mystères, ses ruines, et son musée. Inscriptions have also been published in the Bulletin de correspondance hellénique. (E. Gr.)

**ELEUTHERIUS**, pope from about 175 to 189. Allusions to him are found in the letters of the martyrs of Lyons, cited by Eusebius, and in other documents of the time. The Liber Pontificalis, at the beginning of the 6th century, says that he had relations with a British king, Luxvior, who was desirous of being converted to Christianity. This tradition—Roman, not British—is an enigma to critics, and, apparently, has no historical foundation. (L. D.)

**ELEUTHEROPOLIS** (Gr. Ἐλευθερόπολις, "free city"), an ancient city of Palestine, 25 m. from Jerusalem on the road to Gaza, identified by E. Robinson with the modern Beit Jibrin. This identification is confirmed by Roman milestones in the neighbourhood. It represents the Biblical Marahshah, the ruins of which exist at Tell Sandannahah close by. As Betogabra it is mentioned by Ptolemy; the name Eleutheropolis dates from the Syrian visit of Septimius Severus (A.D. 202). Eusebius in his *Onomasticon* uses it as a central point from which the distances of other towns are measured. It was destroyed in 756, rebuilt by the crusaders in 1134 (their fortress and chapel remain, much ruined). It was finally captured by Bibars, 1244. Beit Jibrin is in the centre of a district of great archaeological interest. Besides the crusader and other remains in the village itself, the surrounding country possesses many tellis (mounds) covering the sites of ancient cities. The famous caves of Beit Jibrin honeycomb the hills all round. These are immense artificial excavations of unknown date. Roman milestones and aqueducts also are found, and close by the now famous tomb of Apollonphanes, with wall-paintings of animals and other ornamentation, was discovered in 1902; a description of it will be found in Thiersch and Peters, *The Marissa Tombs*, published by the Palestine Exploration Fund. (R. A. S. M.)

**ELEVATORS**, LIFTS or HOISTS, machines for raising or lowering loads, whether of people or material, from one level to another. They are operated by steam, hydraulic or electric power, or, when small and light, by hand. Their construction varies with the magnitude of the work to be performed and the character of the motive power. In private houses, where small weights, as coal, food, &c., have to be transferred from one floor to another, they usually consist simply of a small counter-balanced platform: suspended from the roof or an upper floor by a tackle, the running part of which hangs from top to bottom and can be reached and operated at any level. In buildings where great weights and numbers of people have to be lifted, or a high speed of elevation is demanded, some form of motor is necessary. This is usually, directly or indirectly, a steam-engine or occasionally a gas-engine; sometimes a water-pressure engine is adopted, and it is becoming more and more common to employ an electric motor deriving its energy from
the general distribution of the city. Large establishments, hotels or business houses, commonly have their own source of energy, an electric or other power "plant," on the premises.

The hydraulic elevator is the simplest in construction of elevators proper, sometimes consisting merely of a long pipe set deeply in the ground under the cage and containing a correspondingly long plunger, which rises and falls as required and carries the elevator-cage on its upper end (fig. 1). The "stroke" is thus necessarily equal to the height traversed by the cage, with some surplus to keep the plunger steady within its guiding-pipe. The pipe or pump

---

**Fig. 1.**—The Plunger, or Direct Lift Hydraulic Engine.

The chamber has a length exceeding the maximum rise and fall of the plunger, and must be strong enough to sustain safely the heavy hydraulic pressures needed to raise plunger and cage with load. The power is usually supplied by a steam pump (occasionally by a hydraulic motor), which forces water into the chamber of the great pipe as the elevator rises, a waste-cock drawing off the liquid in the process of lowering the cage. A single handle within the cage generally serves to apply the pressure when raising, and to reduce it when lowering the load. The most common form of hydraulic elevator, for important work and under usual conditions of operation, as in cities, consists of a suspended cage, carried by a tackle, the running part of which

ELEVATORS

is connected with a set of pulleys at each end of a frame (fig. 2). The rope is made fast at one end, and its intermediate part is carried round first one pulley at the farther end of the frame and then round another at the nearer end, and so on as often as is found advisable in the particular case. The two pulley shafts carrying these two sets of pulleys are made to traverse the frame in such a way as, by their separation, to haul in on the running part, or, by their approximation, to permit the weight of the cage to haul out the rope. By this alternate hauling and "rendering" of the rope the cage is raised and lowered. The use of a number of parallel and independent sets of pulleys as assured of in case of the breaking of any one, each being strong enough alone to hold the load. The movement of the pair of pulley shafts is effected by a water-pressure engine, actuating the plunger of a pump which is similar to that used in the preceding apparatus, but being relatively of short stroke and large diameter, is more satisfactory in design and construction as well as in operation. Electricity may be applied to elevators of this type by attaching the travelling sheaves to a nut in which works a screwed shaft driven by an electric motor. In other electric lifts the cables which support the cage are wound on a drum which is turned by a motor, the drum being connected to the motor-shaft either by a series of pinions or by a worm-gear. The drum may also be worked by a steam or gas engine. Where the traffic is not very heavy, a form of elevator that requires no attendant is convenient. In this one any wishing to use the lift has merely to press a button placed on the floor of the lift-gate, which opens it to being standing, when the car will come to him; and having entered it he can cause it to travel to any floor he desires by pressing another button inside the car. The motive power in such cases may be either electric or hydraulic, but the control of the switches or valves that govern the action of the apparatus is electric.

The history of the elevator is chronologically extensive, but only since 1850 has rapid or important progress been effected. In that year George H. Fox & Co. built an elevator operated by the motion of a vertical screw, the nut on which carried the cage. This device was used in a number of instances, especially in hotels in the large cities, during the succeeding twenty years, and was then generally supplanted by the hydraulic lift of the kind already described as the plunger-lift. With the increased demand for power, speed, safety, convenience of manipulation, and comfort in operation, the inventive ability of the engineer developed the various systems more and more perfectly, and experience has shown that the best adapted and the best construction of each for its peculiar work. Whatever the class, the following are the essentials of design, construction and operation: the elevator must be safe, comfortable, speedy and convenient, must not be too expensive in either first cost or maintenance, and must absolutely trustworthy. It must not be liable to fracture of any element of the hoisting gear that will permit either the fall of the cage or its projection by an over-weighted balance upwards against the top of its shaft. It must be possible to stop it, whether in regular working or in emergency, or when accident occurs, with sufficient promptness, yet without endangering life or property, or even very seriously inconveniencing the passengers. Acceleration and retardation in starting and stopping must be smooth and easy, the stop must be capable of being made precisely where and when intended, and no danger must be incurred by the passengers from contact with running parts of the mechanism or with the walls and doors of the elevator shaft.

These requirements have been fully met in the later forms of elevator commonly employed for passenger service. Usual sizes range from loads of 1000 to 5000 lb with speeds of from 80 to 250 ft. a minute unloaded, and 75 to 200 ft. loaded, and a height of travel of from 50 to 200 ft. In some very tall buildings, as the Singer and Metropolitan buildings in New York, elevators have been installed having a maximum speed of 600 ft. a minute, with a rise of over 500 ft. Where electric motors are employed, their speed ranges from 600 and 700 revolutions per minute in the larger to 1000 and 1200 in the smaller sizes, corresponding to from 20 down to 4 or 5 h.p. Two or more counter-weights are employed, and from four to six suspension cables ensure as nearly as possible absolute safety. The electric elevators of the Central London railway are guaranteed to raise 17,000 lb 65 ft. in some of its shafts, in 30 secs. from start to stop. Over 100,000 ft. of 4-in. and 17,000 ft. of 3-in. steel rope are required for its 24 shafts, and each rope can carry from 16 to 22 tons without breaking. The steel used in the cables, of which there are four for each car and counter-weight, has a tensile strength of 85 to 90 tons in 1 in. of section of wire. The maximum pull on each set of rope is assumed to be not over 9000 lb, the remainder of the load being taken by the counter-balance. Oil "dash-pots" or buffers, into which enter plungers attached to the bottom of the cage, prevent too sudden a stop in case of accident, and safety-clutches with friction adjustments of ample power and fully tested before use give ample insurance against a fall even if all the cables should yield at once—an almost inconceivable contingency. The efficiency, i.e. the ratio of work performed to power expended in the same time, was in these elevators found by test to be between 70 and 75 %.

Safety devices constitute perhaps the most important of the later improvements in elevator construction where passengers are carried. The simplest and, where practicable, most certain of them is the "air-cushion," a chamber into which the cage drops if detached or from any cause allowed to fall to the bottom of the shaft, thereby compressing the air bringing it to rest without shock (fig. 3). This chamber must be perfectly air-tight, except in so far as a purposely arranged clearance around the sides, diminishing downwards and in well-established proportion, is adjusted to permit a "dash-pot" action and to prevent rebound. The air-cushion should be about one-tenth the depth of the elevator shaft; in high buildings it may be a well 20 or 30 ft. deep. The Empire building, in New York, is twenty storeys in height, the total travel of the cage is 287 ft., and the air-cushion is 50 ft. deep, extending from the floor of the third storey to the bottom of the shaft. Sliding doors of great strength, and automatic in action, at the first and second floors, are the usual agencies to prevent the cage from falling into the bottom of the shaft, held in position by the resistance of the air. The shaft is tapered for some distance below the third floor, and then carried straight to the bottom. An inlet valve admits air freely as the cage rises, and an adjusted safety-valve provides against excess pressure. A "car," falling freely from the twentieth storey, was checked by this arrangement without injury to a basket of eggs placed on its floor. Other safety devices consist of catches under the floor of the cage, so arranged that they are held out of engagement by the pull on the cables. But if the strain is suddenly relieved, as by breakage of a cable or accident to the engine or motor, they instantly fly into place and, engaging strong side-struts in the shaft, hold the car until it can be once more lifted by its cables. These operate well when the cables part at or near the car, but they are apt to fail if the break occurs on the opposite side of the carrying shafts at the top of the shaft, since the friction and inertia of the mass of the cables may in that case be sufficient to hold the paws out of gear either entirely or until the machinery is so great as to cause the smashing of all resistances when they do engage.

Another principle employed in safety arrangements is the
action of inertia of parts properly formed and attached. Any
dangerous acceleration of the cage causes the inertia of these
parts to produce a retardation relative to the car which throws
into action a brake or a catch, and thus controls the motion
within safe limits or breaks the fall. The hydraulic brake has
been used in this apparatus, as have mechanical and pneumatic
apparatus. This control of the speed of fall is most commonly
secured by the employment of a centrifugal or other governor
or regulator. The governor may be on the top of the cage and
driven by a stationary rope fixed between the top and bottom of
the shafts, or it may be placed at the top of the shaft and driven
by a rope travelling with the car. Its action is usually to trip
into service a set of spring grips or friction clutches, which,
as a rule, grasp the guides of the cage and by their immense
pressure and great resultant friction bring the cage to rest within
a safe limit of speed, time and distance. A coefficient of friction
of about 15% is assumed in their design, and this estimate is
confirmed by their operation. Pressures of 10 tons or more are
sometimes provided in these grips to ensure the friction required.
There are many different forms of safety device of these various
classes, each maker having his own. The importance of absolute
safety against a fall is so great that the best builders are not
satisfied with any one form or principle, but combine provisions
against every known danger, and often duplicate such precautions
against the most common accidents.

The "travelling staircase," which may be classed among the
passenger elevators, usually consists of a stair case so constructed
that it is a center of the building. It is by Hope and Glory, it is
also ascending at a predetermined rate, so that the progress made
is the sum of the two rates of motion. The system of "treads and
risers" is carried on a long endless band of chain sustained by
guides holding it in its desired line, and rendering at either end
over cylinders or sprockets. The junctions between the stairway
and the upper or lower floors are ingeniously arranged so as to
avoid danger of injury to the passengers.

Freight elevators have the same general forms as the passenger
elevators, but are often vastly larger and more powerful, and
are not as a rule fitted up for such heights of lift, or constructed
with such elaborate provision for safety or with any special
finish. Elevators raising grain, coal, earth and similar materials,
such as can be taken up by scooping into a bucket, or can be run
into and out of the bucket by gravity, constitute a class by them-
selves, and are described in the article CONVEYORS.

The term "elevator" is often used to include buildings
as well as machinery, and it is not unusual in Europe to hear a
floors of a system of motor machinery, mills, elevator and
storage departments, spoken of as an "American elevator"
(see GRANARIES).

ELF. (O. Eng. ælf; cf. Ger. Alp, nightmare), a diminutive
supernatural being of Teutonic mythology, usually of a more or
less mischievous and malignant character, causing diseases and
evil dreams, stealing children and substituting changelings,
and thus somewhat different from the Romanic fairy, which
usually has less sinister associations. The prehistoric phe-
notheaded and other flint implements were in England early known as
"elf-holds" or "elf-arrows," and were looked on as the weapons
of the elves, with which they injured cattle. So too a tangle in
the hair was called an "elf-lock," as being caused by the mischief
of the elves.

ELGAR, SIR EDWARD (1857- ). English musical com-
poser, son of W. H. Elgar, who was for many years organist in
the Roman Catholic church of St. George at Worcester and
driven there the 2nd of June, 1857. His father's connection
with music at Worcester, with the Glee Club and with the Three
Choirs Festivals, supplied him with varied opportunities for a
musical education, and he learnt to play several instruments.
In 1879 he became bandmaster at the county lunatic asylum,
and held that post till 1884. He was also a member of an orchestra
at Birmingham, and in 1883 an intermezzo by him was played
there at a concert. In 1885 he became conductor of the
Worcester Amateur Instrumental Society, and in 1888 he
succeeded his father as organist at St. George's, Worcester. There he
wrote a certain amount of church music. In 1889 he moved
to London, but finding no encouragement retired to Malvern
in 1891; in 1904 he went to live at Hereford, and in 1905 was made
professor of music at Birmingham University. To the public
generally he was hardly known till his oratorio The Dream of
Geronutus was performed at Birmingham in 1900, but this was at
once received as a new revelation in English music, both at home
and by Richard Strauss in Germany, and the composer was made a
Mus. Doc. at Cambridge. His experience in writing church
music for a Roman Catholic service cannot be overlooked in
regard to Sir Edward Elgar, although he was not as the representa-
tive of a Catholic or neo-Catholic style of
religious music, for which an appreciative public was ready
in England at the moment, owing to the recent developments in
the more artistic and sensuous side of the religious movement.
And the same interest attached to his later oratorios, The Apostles
(1903) and The Kingdom (1906). But Elgar's sudden rise into
popularity, confirmed by his being knighted in 1904, drew
attention to his other productions. In 1896 his Scenes from the
Sage of King Olaf was recognized by musicians as a fine work,
and in the same year his Scenes from the Bavarian Highlands
and Lux Christi were performed; and apart from other important
compositions, his song-cycle Sea-Pictures was sung at Norwich
in 1899 by Clara Butt, and his orchestral Variations on an
original theme were given at a Richter concert in the same year.
In 1901 his popular march "Pomp and Circumstance" was
played at a promenade concert, the stirring melody of his song-
cycle Faust and the whole of Elgar's music being effectively utilized.
It is impossible here to enumerate all Sir Edward Elgar's works, which
have excited a good deal of criticism in musical circles without
impairing his general recognition as one of the few front-rank
English composers of his day; but his most important later
production, his first orchestral symphony, produced in 1908
with immediate success, raised his reputation as a composer to
an even higher plane, as a work of marked power and beauty,
developing the symphonic form with the originality of a real
master of his art. In 1908 he resigned his professorship at
Birmingham University.

ELGIN, a city of Kane county, Illinois, U.S.A., in the N.
part of the state, 36 m. N.W. of Chicago. Pop. (1880) 897;
(1890) 17,823; (1900) 22,433, of whom 5419 were foreign-born;
(1910 Census) 25,976. Elgin is served by the Chicago & North-
Western and the Chicago, Milwaukee & St Paul railways, and by
interurban electric railways to Chicago, Aurora and Batavia.
The city is the seat of the Northern Illinois hospital for the
insane, of the Elgin Academy (chartered 1839; opened 1856),
and of St Mary's Academy (Roman Catholic); and has the Gail
Borden public library, with 35,000 volumes in 1908. The city
has six public parks, Lord's Park containing 112, and Wing
Park 121 acres. The city is in a fine dairying region and is
an important market for butter. Among Elgin's manufactures
are watches and watch-cases, butter and other dairy products,
cooperage (especially butter tubs), canned corn, shirts, factory and
machine-shop products, pipe-organs, and caskets and casket
trimmings; in 1905 Elgin's total factory product was valued at
$3,349,274. The Elgin National Watch factory, and the Borden
milk-condensing works, are famous throughout the United States
and beyond. The publishing office of the Dunkers, or German
Brethren, is at Elgin; and several popular weeklies with large
circulations are published here. A permanent settlement was
made as early as 1835, and Elgin was chartered as a city in 1854
and incorporated in 1892. It is the site of the Illinois state
university, and the Elgin Academy, the second oldest high
school in the state.

ELGIN, a royal, municipal and police burgh, and
county town of Elginshire, Scotland, situated on the Nessie, 5
m. S. of Lossiemouth its port, on the Moray Firth, and 71 m. N.W.
of Aberdeen, with stations on the Great North of Scotland and
Highland railways. Pop. (1901) 8460. It is a place of very con-
siderable antiquity, was created a royal burgh by Alexander I.,
and received its charter from Alexander II. in 1294.

The castle of Elgin lay at the centre of the town, and in 1292, it was
burned by the English, and in 1382 its castle, and in 1386 he
succeeded his father as organist at St George's, Worcester. There he

The hill on which it stood was renamed the Ladyhill, and on the scanty ruins of the castle now stands a monument to the 5th duke of Gordon, consisting of a column surmounted by a statue. The church for many years was one of the chief churches of Scotland, and was visited by many nobles and statesmen. Montrose plundered it twice in 1645. In 1746 Prince Charles Edward spent a few days in Thunderton House. His hostess, Mrs Anderson, an ardent Jacobite, kept the sheets in which he slept, and was buried in them on her death, twenty-five years afterwards. For fifty years after this date the place retained the character and traditions of a sleepy cathedral city, but with the approach of the 19th century it was touched by a more active spirit. As the result much that had been desolate was repaired, but the prosperity of Elgin was increased, so that now, owing to its pleasant situation in the Garden of Scotland, its healthy climate, cheap living, and excellent educational facilities, it has become a flourishing community. The centre of interest is the cathedral of Moray, which was founded in 1224, when the church of the Holy Trinity was converted to this use. It was partially burned in 1270 and almost destroyed in 1350 by Alexander Stewart, the Wolf of Badenoch, natural son of Robert II., who had incurred the censure of the Church. In 1402 Alexander, lord of the Isles, set fire to the town, but spared the cathedral for a consideration, in memory of which mercy the Little Cross (so named to distinguish it from the Muckle or Market Cross, restored in 1888) was erected. After these outrages it was practically rebuilt on a scale of grandeur that made it the most magnificent example of church architecture in the north. Its design is that of a Jerusalem cross, with two flanking towers at the east end, two at the west end, and one in the centre, at the intersection of the roofs of the nave and transepts. It measured 282 ft. long from east to west by 120 ft. across the transepts, and consisted of the choir, the gable of which was pierced by two tiers of lancet windows and the Omega rose window; the north transept, in which the Dunbars were buried; and the south transept, the doorway of which is interesting for its dog-tooth ornamentation; and the nave of five aisles. The grand entrance was by the richly carved west door, above which was the Angel Window. The central steeple fell in 1506, but was rebuilt, the new tower with its spire reaching a height of 198 ft. By 1538 the edifice was complete in every part. Though the Reformation left it unscathed, it suffered wanton violence from time to time. By order of the privy council the lead wasstripped off the roofs in 1567 and sold to Holland to pay the troops; but the ship conveying the spoils foundered in the North Sea. In 1660, by the roof-tree of the choir priests preached in an open gable, and three years later the rich timber screen was demolished. The central tower again collapsed in 1711, after which the edifice was allowed to go to ruin. Its stones were carted away, and the churchyard, overgrown with weeds, became the dumping-ground for rubbish. It lay thus scandalously neglected until 1824, when John Shanks, a "drouthy" cobbler, was appointed keeper. By a species of inspiration this man, hitherto a ne'er-do-well, conceived the notion of restoring the place to order. Undismayed, he attacked the mass of litter and with his own hands removed 3000 barrow-loads. When he died in 1841 he had cleared away all the rubbish, disclosed the original plan, and collected a quantity of fragments. A tablet, let into the wall, contains an epitaph by Lord Cockburn, recording Shanks's services to the venerable pile, which has since been entrusted to the custody of the commissioners of works and forests. The chapter-house, to the north-east of the main structure, suffered least of all the buildings, and contains a 'Prentice pillar, of which a similar story is told to that of the ornate column in Roslin chapel. In the lavatory, or vestible connecting the chapterhouse with the choir, Marjory Anderson, a poor half-crazy creature, a soldier's widow, took up her quarters in 1748. She cradled her son in the piscina and lived on charity. In the course of time the lad joined the army and went to India, where he rose to the rank of major-general and amassed a fortune of £70,000 with which he endowed the Elgin Institution (commonly known as the Anderson Institution), at the east end of High Street, for the education of youth and the support of old age. Within the precincts of the cathedral grounds stood the bishop's palace (now in ruins), the houses of the dean and archdeacon (now North and South Colleges), and the manses of the canons. Other ecclesiastical buildings were the monasteries of Blackfriars (1230) and Greyfriars (1410) and the preceptory of Maisondieu (1240). They also were permitted to fall into decay, but the 3rd marquess of Bute undertook the restoration of the Greyfriars' chapel. The parish church, in the Greek style, was built in 1828. Gray's hospital, at the west end of High Street, was endowed by Dr Alexander Gray (1731-1808), and at the east end stands the Institution, already mentioned, founded by General Andrew Anderson (1746-1822). Other public buildings include the assembly rooms, the town-hall, the museum (in which the antiquities and natural history of the shire are abundantly illustrated), the district asylum, the academy, the county buildings and the court house, the market buildings, the Victoria school of science and art, and Lady Gordon-Cumming's children's home. In 1903 Mr G. A. Cooper presented his native town with a public park of 42 acres, containing lakes representing on a miniature scale the British Isles. Grant Lodge, an old mansion of the Grant family, occupying the south-west corner of the park, was converted into the public library. From the top of Ladyhill the view commands the links of the Lossie and the surrounding country, and a recreation ground is laid out on Lossie Green. The industries include distilling and brewing, nursery gardening, tanning, saw and flour mills, iron-foundries and manufactures of woollens, tweeds and plaiding, and the quarrying of granite. On the 1st of July, 1809, the 8th regiment, from Edinburgh, Kintore and Peterhead to return one member to parliament, and the town is controlled by a council with provost and bailies. Two miles and a half S. by W. of Elgin stands the church of Barnie, with the exception of the church at Mortlach in Banffshire probably the oldest place of public worship in Scotland still in use. It is not later than 1150 and, with its predecessor, was the cathedral of Moray during the rule of the first four bishops; the fourth bishop, Simon de Toeny, an Englishman, was buried in its precincts in 1184. In the church is preserved an old Celtic altar-bell of hammered iron, known as the "Ronnell bell." Such is the odour of sanctity of this venerable church that there is an old local saying that "to be thrice prayed for in the kirk of Barnie will either mend or end ye." Six miles to the S.W. of Elgin, charmingly situated in a secluded valley encircled by florid cliffs, lies the picturesque remains of Pluscarden Priory, a Cistercian house founded by Alexander II. in 1230. The ruins, consisting of a tower, transept and chapter-house, refectory and other apartments, are nearly hidden from view by a clump of ivy and the fine old trees, including many beautiful examples of copper beech, by which they are surrounded. Its last prior, Alexander Dunbar, died in 1560. The Liber Pluscardensis, a valuable authority on early Scots history, was compiled in the priory by Maurice Buchanan in 1461. The chronicle comes down to the death of James I. The 3rd marquess of Bute acquired the ruins in 1697.

ELGIN AND KINCARDINE, EARLS OF. Thomas Bruce, 7th earl of Elgin (1766-1841), British diplomatist and art collector, was born on the 20th of July 1766, and in 1771 succeeded his brother in the Scottish peerage as the 7th earl of Elgin (cr. 1635), and 11th of Kincardine (cr. 1647). He was educated at Harrow and Westminster, and, after studying for some time at the university of St Andrews, proceeded to the continent, where he studied international law at Paris, and military science in Germany. When his education was completed he entered the army, in which he rose to the rank of general. His general education was, however, devoted to diplomacy. In 1792 he was appointed envoy at Brussels, and in 1795 envoy extraordinary at Berlin; and from 1799 to 1802 he was envoy extraordinary at the Porte. It was during his stay at Constantinople that he formed the purpose of removing from Athens the celebrated sculptures now known as the Elgin Marbles. His doing so was censured by some as vandalism, and doubts were also expressed as to the artistic value of many of the marbles; but he vindicated himself
ELGIN AND KINCARDINE, EARLS OF

In a pamphlet published in 1810, and entitled Memorandum on the Subject of the Earl of Elgin’s Pursuits in Greece. In 1816 the collection was purchased by the nation for £50,000, and placed in the British Museum, the outlay incurred by Lord Elgin having been more than £50,000. Lord Elgin was a Scottish representative peer for fifty years. He died at Paris on the 14th of November 1841.

James Bruce, 8th earl of Elgin (1811–1863), British statesman, eldest son of the 7th earl by his second marriage, was born in 1811, and succeeded to the peerage as 8th earl of Elgin and 12th of Kincairdine in 1841. He was educated at Eton and at Christ Church, Oxford, where he had an excellent training, and rivaled his younger predecessors in the office of governor-general in India, Dalhousie and Canning. He began his official career in 1842 at the age of thirty, as governor of Jamaica. During an administration of four years he succeeded in winning the respect of all classes. He improved the condition of the negroes and conciliated the planters by working through them. In 1846 Lord Grey appointed him governor-general of Canada. Son-in-law of the popular Earl of Durham, he was well received by the colonists, and he set himself deliberately to carry out his Durham policy. In this his frank and genial manners aided him powerfully. His assent to the local measure for indemnifying those who had suffered in the troubles of 1837 led the mob of Montreal to pelt his carriage for the rewarding of rebels for rebellion, as Mr Gladstone described it. But long before his eight years’ term of service expired he was the most popular man in Canada. His relations with the United States, his hearty support of the self-government and defence of the colony, and his settlement of the free-trade and fishery questions, led to his being raised in 1849 to the British peerage as Baron Elgin.

Soon after his return to England in 1854, Lord Palmerston offered him a seat in the cabinet as chancellor of the duchy of Lancaster, which he declined. But when, in 1856, the seizure of the "Arrow" by Commissioner Yeh plunged England into war with China, he at once accepted the appointment of special envoy with the expedition. On reaching Point de Galle he was met by a force summoned from Bombay to Calcutta by the news of the sepoy mutiny at Meerut on the 11th of May. His first idea, that the somewhat meagre intelligence would justify most energetic action in China, was at once changed when urgent letters from Lord Canning reached him at Singapore, the next port, on the 3rd of June. H.M.S."Shannon" was at once sent on to Calcutta with the troops destined for China, and Lord Elgin himself followed it, when glosemer letters from India reached him. The arrival of the "Shannon" gave new life to the hands of the fighting against the Chinese, and before the reinforcements from England arrived the back of the mutiny had been broken. Nor was the position in China seriously affected by the want of the troops. Lord Elgin sent in his ultimatum to Commissioner Yeh at Canton on the same day, the 12th of December, that he learned the relief of Lucknow, and he soon after sent Yeh a prisoner to Calcutta. By July 1858, after months of Chinese deception, he was able to leave the Gulf of Pehchil with the emperor’s assent to the Treaty of Tientsin. Subsequently he visited Japan, and obtained less considerable concessions from its government in the Treaty of Yedo. It is true that the negotiations were confined to the really subordinate Tycoon or Shogun, but that visit proved the beginning of British influence in the most progressive country of Asia. Unfortunately, the Chinese difficulty was not yet at an end. After tedious disputes with the tariff commissioners as to the opium duty, and a visit to the upper waters of the Yang-tzse, Lord Elgin had reached England in May 1859. But when his brother and the allied squares were to proceed to Peking with the ratified treaty, they were fired on from the Taku forts at the mouth of the Peiho. The Chinese had resolved to try the fortune of war once more, and Lord Russell again sent out Lord Elgin as ambassador extraordinary to demand an apology for the attack, the execution of the treaty, and an indemnity for the military and naval expenditure. Sir Robert Napier (afterwards Lord Napier of Magdala) and Sir Hope Grant, with the French, so effectually routed the Tatar troops and sacked the Summer Palace that by the 24th of October 1860 a convention was concluded which was entirely satisfactory to Her Majesty’s government. Lord Elgin had not been a month, but some weeks, when Lord Palmerston selected him to be viceroy and governor-general of India. He had now attained the object of his honourable ambition, after the office had been filled in most critical times by his juniors and old college companions, the marquis of Dalhousie and Earl Canning. He succeeded a statesman who had done much to reorganize the whole administration of India, shattered as it had been by the Mutiny. But, as the first viceroy directly appointed by the Crown, and as subject to the secretary of state for India, Lord Elgin at once gave vent to the feelings that the co-ordinate independence, or rather the stimulating responsibility, of the governor-general, which had prevailed from the days of Clive and Warren Hastings. On the other hand, he loyally carried out the wise and equitable policy of his predecessor towards our feudatories with a firmness and a dignity that in the case of Holkar and Udaipur had a good effect. He did his best to check the aggression of the Dutch in Sumatra, which was contrary to treaty, and he supported Dost Mohammed in Kabul until an aged warrior entered into the territory of Herat. Determined to maintain inviolate the integrity of our own north-west frontier, Lord Elgin assembled a camp of exercise at Lahore, and marched a force to the Peshawar border to punish those branches of the Yusufzai tribe who had violated the engagements of 1858.

It was in the midst of this "little war" that he died. Soon after his arrival at Calcutta, he had projected the usual tour to Simla, to be followed by an inspection of the Punjab and its warlike ring-fence of Pathans. He even contemplated the summoning of the central legislative council at Lahore. After passing the summer of 1863 in the cool retreat of Peterhoff, Simla, Lord Elgin began a march across the hills from Simla to Sialkot by the upper valleys of the Beas, the Ravi and the Chenab, chiefly to decide the two allied questions of tea cultivation and trade routes to Kashgar and Tibet. The climbing up to the Rotung Pass (13,000 ft) which separates the Beas valley from that of the Chenab, and the crossing of the frail twig bridge across the Chundra torrent, prostrated him by the time he had descended into the smiling English-like Kangra valley. Thence he wrote his last letter to Sir Charles Wood, still full of hope and not free from anxiety as to the Sattana expedition. At the lovely hill station of Dharmasala, "the place of piety," he died of fatty degeneration of heart on the 20th of November 1863.

For his whole career see Letters and Journals of James, Eighth Earl of Elgin, edited by W.E. Gladstone and published by the Duke of Devonshire, Dean Stanley; for the China missions see Narrative of the Earl of Elgin's Mission to China and Japan, by Laurence Oliphant, his private secretary; for the brief Indian administration see the Friend of India for 1862–1863.

Victor Alexander Bruce, 9th earl of Elgin (1849– ), British statesman, was born on the 16th of May 1849, the son of the 8th earl, and was educated at Eton and Balliol College, Oxford. In 1863 he succeeded as 9th earl of Elgin and 13th of Kincardine. A Liberal in politics, he became first commissioner of works (1886), and subsequently viceroy of India (1894–1899). His administration in India was chiefly notable for the frontier risings of 1879–1879. The Afridis broke out into a fanatical revolt and through hesitation on the part of the government were allowed to seize the Khayer Pass, necessitating the Tirah Expedition. After his return to England he was nominated chairman of the royal commission to investigate the conduct of Kinsgville's daughter, Sir Henry Campbell-Bannerman's ministry in December 1905, he became a member of the cabinet as secretary of state for the colonies. In this capacity, though he showed many statesmanlike qualities, he was somewhat overshadowed by his brilliant under-secretary in the Commons, Mr Winston Churchill, whose speeches on colonial affairs were as aggressive as Lord Elgin's were cautious; and when in April 1908, Mr Asquith became prime minister, Lord Elgin retired from the cabinet.
ELGINSHIRE, or MORY (Gaelic "among the sea-board men"), a northern county of Scotland, bounded N. by the Moray Firth, E. and S.E. by Banffshire, S. and S.W. by Inverness and W. by Nairnshire. It comprises only the eastern portion of the ancient province of Moray, which extended from the Spey to the Firth of Forth, from the Carse of Gowrie to the sea, embracing an area of about 350 sq. m. The area of the county is 355,119 acres, or 477 sq. m.

Elginshire is naturally divided into two sections, the level and fertile coast and its hinterland—"the Laigh o' Moray," a tract 30 m. long by 920 m. broad—and the hilly country in the south. There are, however, no high mountains. Carn Righi (1784 ft.), Larig Hill (1783) and Carn Kitty (1712) are the chief elevated points south of the Moray Firth. The Tyrell, one of the largest rivers in the county, runs westward to the sea, its valley being represented by the Cawdor burn, which empties into the Moray Firth near the town of Cawdor. The Moray Firth, which forms the northern boundary of the county, is an arm of the sea, its western shore being composed of sandstones, shales and clays, with limestone nodules containing fish remains. This sequence is well displayed in the banks of the Spey and in the Clackmannanshire district, where the Moray and the latter being one of the well-known localities for ichthyoliths in the middle or Orcadian division. In the Tynet and Gollachie Burn sections, the fish bed is overlaid by conglomerates and red pebbly sandstones, passing upwards into a thin zone of sandstones and conglomerates, indicating contemporaneous volcanic action. West of the Tynet Burn and Spey sections there is no trace of the members of the Orcadian division till we reach the Muckle Burn and Lettherin Burn, in Nairnshire, to save the coarse conglomerate filling the ancient hollow of the valley of Rothes which may belong to the middle series. In the west section they are overlapped by the Upper Old Red Sandstone, which in the Moray Firth, in the Lochty Burn and the Findhorn rest directly on the metamorphic rocks. The rocks of the main boundary of the upper division there are small outliers of that formation on the crests of the hills, and there are also small outliers of the same nature between the Moray Firth and the Moray Firth Burn. The Upper Old Red Sandstone in this county is arranged in two groups, the Alves and Rosebrae. The area lying to the north of the Upper Red Sandstone ridge at Bishopmill and Quarry Bank, west of the Moray Firth, is occupied by the Trias, which consists of pale-grey and yellow sandstones and a peculiar cherty and calcarceous band, known as the cherty rock of Strofie. The sandstones are visible in quarries on the north slope of Quarry Wood, at Findraesie, at Spynie and along the ridge and sea-shore between Burghhead and Lossiemouth. They are invested with special interest on account of the remarkable series of reptilian remains obtained from them, comprising *Stagonolepis*, a crocodile allied to the modern caiman in form; *Tetraplon* and *Hypereropodon*, species of lizards; *Dyscynodon* (Gordonia and Gehis) and a horned reptile, *Elginia* (see SCOTLAND: Reptiles). The paleontologists are of the opinion that the occurrence of these reptilian beds must belong to the Trias, indeed it is possible that the lower position of the Trias may be of Permian age. In the county of Elgin, these reptilian beds rest directly on the sandstones containing *Hoplocythus* of Upper Old Red Sandstone age, so that the apparent conformability must be entirely deceptive. Within the limits of the county is occupied by the Trias, which is overlaid by the Miocene, charged with fish scales of Upper Old Red age, where they form a low ridge protruding through the younger strata. The Upper Old Red and Triassic sandstones have been studied with special care for building purposes. On the shore at Lossiemouth there is a patch of greenish white sandstones yielding fossils characteristic of the Lower Oolite.

The glacial deposits distributed over the fertile plain of Moray and in the upland valleys are of interest. The low grounds were crossed by the ice descending the Moray Firth in an easterly and north-easterly direction. The northern extremity of the ice, near Strath Nairn and Auchenstarry from Easter Ross. In the Moray Firth district, boulders belonging to the horizons of the Lower and Middle Lias, the Oxford Clay and the Upper Chalk are found in the glacial deposits and on the surface of the ground. The largest transported mass occurs at Linksfield, where a succession of limestone and shales rests on boulder clay and is covered by it, from which the fossil may be of Rhaetic or Lower Lias age.

**Climate and Agriculture.**—The climate of the coast is equable and mild, even exotic fruits ripening readily in the open. The uplands are colder and damp. The average temperature in January is 38° F. and in July 58° F., while for the year the mean is 47° F. The rainfall for the year averages 26 in. Considering its latitude and the extent of its arable land the standard of farming in Elginshire is high. The rich soil of the lowlands is well adapted for wheat, barley and oats. The acreage contained...
ELGINSHIRE

to the glens and straths under barley approximates that under oats. In the uplands, oats is the principal cereal. The breeding of live-stock is profitable, and some of the finest specimens of short-horned and polled cattle and of crosses between the two are bred. On the larger farms in the Leight Leitch sheep are kept all the year round, but in the uplands the Blackfaced take their place. Large numbers of horses and pigs are also raised.

Other Industries.—Whisky is the chief product, and the numerous distilleries are usually busy. There are woolen mills at Elgin and elsewhere and chemical works at Forres and Burghead. Owing to the absence of coal what little mineral wealth there is (iron and lead) cannot be remuneratively worked. The sandstone quarries, yielding a building-stone of superior quality, are practically inexhaustible. The plantations mainly consist of larch and fir and, to a smaller extent, of oak. Much timber was once floated down the Spey and other rivers, but, since the increased facilities of carriage afforded by the railways, trees have been felled on a wider scale. Boat-building is carried on at Burghead, Lossiemouth and Kingstontown—so called from the fact that a firm from Kingston-on-Hull laid down a yard there in 1784—while at Garmouth the fishing fleet lies up during the winter and is also repaired there. The Firth fisheries are of considerable value. The boats go out from Findhorn, Burghead, Lossiemouth, which has a good safe harbour. Findhorn has been twice visited by calamity. The first village was overwhelmed by the drifting sands of Cullin, and the second was buried beneath the waves in 1701. Kingstontown harbour is tidal, exposed, and liable to interruption from a shifting bar. The deep sea fisheries comprise haddock, cod, ling and herring, and the Spey, Findhorn and Lossie yield large quantities of salmon.

The Great North of Scotland railway enters the shire in the S.E. from Craigellachie, whence a branch runs up the Spey to Boat of Garten in Inverness-shire, and in the N.E. from Port Gordon, running in both cases to Elgin, from which a branch line extends to Lossiemouth. The Highland railway traverses the western limits of the shire running almost due north to Forres, whence it turns westward to Nairn and eastward to Elgin. From the county town it runs to Aberdeen via Orbiston and Keith, with a branch to Forchabers from Orbiston.

Population and Government.—The population was 43,471 in 1801 and 44,800 in 1901, when 1865 persons spoke both Gaelic and English, and 2 spoke Gaelic only. The chief towns are Elgin (pop. in 1901, 8,460), Forres (4,313) and Lossiemouth (3,904), to which may be added Rothes (1,621), Grantown (1,568) and Burghead (1,531). In conjunction with Nairnshire the county returns one member to parliament. Elgin and Forres are royal burghs; the municipal and police burghs include Burghead, Elgin, Forres, Grantown, Lossiemouth, and Rothes. Elginshire is divided in one sheriffdom with Inverness and Nairn, and there is a resident sheriff-substitute at Elgin. The county is under school-board jurisdiction, several of the schools earning grants for higher education. There are academies at Elgin and Forchabers and science and art and technical schools at Elgin and Grantown. The bulk of the "residue" grant is spent in subsiding the agricultural department of Aberdeen University and the science schools and art and technical classes in the county. 

History.—Moray, in the wider sense, was first peopled by Picts of the Gaelic branch of Celts, of whom relics are found in the stone circle at Viewfield and at many places in Nairnshire. Christianity, introduced under the auspices of Columba (from whose time the site of Burghead church has probably been occupied), flourished for a period until the Columban church was expelled in 777 by King Nectan. Thereafter the district was given over to intermittent strife between the northern and southern Picts, which was ended by the crushing victory of Kenneth MacAlpine in 831, as one result of which the kingdom of Pictavia was superseded by the principality of Moravia. Still, settled order had not yet been secured, for the Norsemen raided the country first under Thorstein and then under two Sigurds. It was in the time of the second Sigurd that the Firth was fixed as the northern boundary of Moray. In spite of such interruptions as the battle of Torfness (Burghead) on the 14th of August 1040, in which Thorfinn, earl of Orkney and Shetland, overthrew a strong force of Scots under King Duncan, the consolidation of the kingdom was being gradually accomplished. After Macbeth ascended the throne the Scandinavians held their hands though Macbeth and his foeman successor, "daft" Lulach, were the disturbers within Moray, the province never lacked for able, if headstrong, men, and it continued to enjoy home rule under its own marmar, or great steward (the equivalent of earl, the title that replaced it), until the dawn of the 12th century, when as an entity it ceased to exist. With a view to breaking up the power of the marmars David I. and his successors colonized the seaboard with settlers from other parts of the kingdom. Nevertheless, from time to time the clansmen and their chiefs descended from their fastnesses and plundered the Laigh, keeping the people for generations in a state of panic. Meanwhile, the Church had become a civilizing force. In 1107 Alexander had founded the see of Moray and the churches of Birnie, Kinneddar and Spynie were in turn the cathedral of the early bishops, until in 1224 under the episcopate of Andrew of Moray (de Moravia), the church of the Holy Trinity in Elgin was chosen for the cathedral. Another factor that drew men together was the struggle for independence. In his efforts to stamp out Scottish nationality Edward I. came as far north as Elgin, where he stayed for four days in July 1296, and whence he issued his writ for the parliament at Berwick. Wallace, however, had no doughtier supporter than Sir Andrew Moray of Bothwell, and Bruce recognized the assistance he had received from the men of the north by erecting Moray into an earldom on the morrow of Bannockburn and bestowing it upon Thomas Randolph (see MORAY, THOMAS RALDOOLPH, EARL OF). Henceforward the history of the county resolved itself in the main into matters affecting the power of the Church and the ambitions of the Moray dynasties. The Church accepted the Reformation peacefully if not with gratitude. But there was strife between Covenanters and the adherents of Episcopacy until, prelacy itself being abolished in 1689, the bishopric of Moray came to an end after an existence of 581 years. (For the subsequent history of the earldom, which was successively held by the Randolphs, the Dunbars, the Douglases, the royal Stewarts and an illegitimate branch of the Stewarts, see MURRAY or MORAY, EARLS OF.) Other celebrated Moray families who played a more or less strenuous part in local politics were the Gordons, the Grants and the Duffs. Still, national affairs occasionally evoked interest in Moray. In the civil war Montrose ravaged the villages which stood for the Covenanters, but most of the great lairds shifted in their allegiance, and the mass of the people were quite indifferent. Charles II. landed at Garmouth on the 3rd of July 1650 on his return from his first exile in Holland, but hurried southwards to try the yoke of Presbyterianism. The fight at Cromdale (May day, 1690) shattered the Jacobite cause, for the efforts in 1715 and 1745 were too spasmodic and half-hearted to affect the loyalty of the district to Hanoverian rule. A few weeks before Culloden Prince Charles Edward stayed in Elgin for some days, and a month afterwards the Duke of Cumberland passed through the town in his triumphal progress. The sandy waste measures 3 m. in length and 2 in breadth, and the sand, exceedingly fine and light, is constantly shifting and, at rare intervals, exposing traces of the vanished demesne. This wilderness of dome-shaped dunes divided by a loftier ridge lies to the north-west of Forres. The other calamy was the Moray floods of the 2nd and 3rd of
August 1829. The Findhorn rose 50 ft. above the ordinary level, inundating an area of 20 sq. m.; the Divie rose 40 ft., and the Lussie flooded all the ground around Elgin. The floods tore down bridges and buildings, and obliterated farms and homesteads.

ELGON, also known as MASAWA, an extinct volcano in British East Africa, cut by 1° N. and 34°E, forming a vast isolated mass over 40 m. in diameter. The outer slopes are in great measure precipitous on the north, west and south, but fall more gradually to the east. The southern cliffs are remarkable for extensive caves, which have the appearance of water-worn caves on a coast line and have for ages served as habitations for the native tribes. The upper parts slope gently upwards on either side of an old crater, lying somewhat north of the centre of the mass, and measuring some 8 m. in diameter. The highest point of the rim is about 14,100 ft. above the sea. Steep spurs separated by narrow ravines run out from the mountain, affording the most picturesque scenery. The ravines are traversed by a great number of streams, which flow north-west and west to the Nile (through Lake Choga), south and south-east to Victoria Nyanza, and north-east to Lake Rudolf, by the Turkwell, the head-stream of which rises within the crater, breaking through a deep cleft in its rim. To the north-west of the mountain a grassy plain, swampy in the rains, falls towards the chain of lakes ending in Choga; towards the north-east the country becomes more arid, while towards the south it is well wooded. The outer slopes are clothed in their upper regions with dense forest formed in part of bamboo, especially towards the south and west, in which directions the rainfall is greater than elsewhere. The lower slopes are exceptionally fertile on the west, and produce bananas in abundance. On the north-west and north the region between 6000 and 7000 ft. possesses a delightful climate, and is well watered by streams of ice-cold water. The district of Save on the north is a halting-place for Arab and Swahili caravans going north. On the west the slopes are densely inhabited by small Bantu-Negro tribes, who style their country Masawa (whence the alternative name for the mountain); but on the south and north there are tribes which seem akin to the Gallas. Of these, the best known is the El-gom, from whom the name of the mountain has been derived. They formerly lived almost entirely in the caves, but many of them have descended to villages at the foot of the mountain. Elgon was first visited in 1883 by Joseph Thomson, who brought to light the cave-dwellings on the southern face. It was crossed from north to south, and its crater reached, in 1890 by F. J. Jackson and Ernest Gedge, while the first journey round it was made by C. W. Hobley in 1896. (E. Hk.)

ELI (Hebrew for "high"; 1 Sam. chap. i.-iv.), a member of the Priesthood founded in Egypt (1 Sam. ii. 27), priest of the temple of Shiloh, the sanctuary of the ark, and also "judge" over Israel. This was an unusual combination of offices, when it is considered that in the history preserved to us he appears in the weakness of extreme old age, unable to control the petulance and rapacity of his sons, Hophni and Phinehas, who disgraced the sanctuary and disgusted the people. While the central authority was thus weakened, the Philistines advanced against Israel, and gained a complete victory in the great battle of Elteben, where the ark was taken, and Hophni and Phinehas slain. On hearing the news Eli fell from his seat and died. In a passage not unlike the account of the birth of Benjamin (Gen. xxxv. 16 sqq.), it is added that the wife of Phinehas, overwhelmed at the loss of the ark and of her husband, died in child-birth, naming the babe Ichabod (1 Sam. iv. 10 sqq.). This name, which popular etymology explained by the words "the glory is removed (or, stronger, 'banished') from Israel" (cf. Hos. x. 5), should perhaps be altered from I-chabod (as though "not glory") to Jochebed (Yohebed, a slight change in the original), the name which tradition also gave to the mother of Moses (q.v.). After these events the sanctuary of Shiloh appears to have been destroyed (cf. Jer. vii. 12, xxvi. 6, 9), and the descendants of Eli with the whole of the clan of El" (i.e., the father's house) subsequently appear as settled at Nob (1 Sam. xxii. iii, 11 sqq., cp. xiv. 3), perhaps in the immediate neighbourhood of Jerusalem (Is. x. 32). In the massacre of the clan by Saul, and the subsequent substitution of the survivor Abiathar by Zadok (1 Kings ii. 27, 35), later writers saw the fulfilment of the prophecies of judgment which was said to have been uttered in the days of Eli against his corrupt house (1 Sam. ii. 27 sqq., iii. 11 sqq.).

See further, Samuel, Books of; and on Eli as a descendant of a Levite clan (1 Sam. ii. 27 sqq.), see Levites (§ 3). (W.R.S.; S-A.C.)

ELIAS, of Cortona (c. 1180-1253), disciple of St Francis of Assisi, was born near Assisi, about 1180, of the working class, but became schoolmaster at Assisi and then notary at Bologna. In 1217 he was the head of the Franciscan mission to the Holy Land, and in 1219 St Francis made him first provincial minister of Syria. When St Francis was recalled from the East in 1220 he brought Elias with him. Elias played a leading part in the history of the Franciscan order (see Franciscans); Francis made him his vicar general in 1221; and he was the practical acting superior of the order till Francis' death in 1226, and the real superior till the general chapter of 1227. This chapter did not elect him minister general, but that of 1232 did; at the chapter of 1230 he was deposed. During these years he erected the basilica and monastery at Assisi which were entirely his creation—he collected the funds and carried the work through himself; he built the church and even the architect. Elias was a man of extraordinary ability, the friend both of Gregory IX. and of his opponent Frederick II. After his deposition Elias joined the party of the emperor and so incurred excommunication. Frederick sent him as ambassador to Constantinople. He dressed and lived as a Franciscan throughout and a small number of friars adhered to him; for these he built a church and monastery at Cortona. Unavailing efforts were made to bring about his reconciliation with the order and the Church; but on his death-bed he made his submission to the pope and died in 1253, having received the Sacraments.

The best account of Elias is that by Ed. Lemp, Prée Bête de Cortone (1901), who points out the conflict of view, as to the relations between Elias and Francis, between the Speculum perfections and the First Life, by Thomas of Celano; Lemp and Sabatier accept the hostile picture given by the Speculum perfections. But see further under "on Ascalon, Saint*, "Note on Sources", and especially the articles by Goetz, the preferred text of this Encyclopaedia. There is a good article on Elias, but written before the new materials had been produced, in Wetzer and Weite, Kirchenlexicon (c/. E. C. B.)

ELIAS, JOHN (1774-1841), Welsh Nonconformist preacher and reformer, was born on the 2nd of May 1774, in the parish of Abererch, Carnarvonshire. In his youth he came under the influence of the Calvinistic Methodist revival and became a preacher at nineteen. In 1799 he married and settled at Llanfechell in Anglesey, giving up his trade as a weaver to become a small shopkeeper. His fame as a preacher increased, and under the direction of Thomas Charles of Bala he established numerous Sunday schools, and gave and secured considerable Welsh support to the founding of the London Missionary Society, the British and Foreign Bible Society and the Religious Tract Society. On Charles's death in 1814 he became the recognized leader of the Calvinistic Methodist Church, and the story of his life is simply a record of marvellously successful preaching tours. He died on the 8th of June 1841; ten thousand people attended his funeral.

* On the old views relating to the succession of the priests, according to which the high-priest was detached from the line of Eleazar and Phinehas into that of Ithamar, see Robertson Smith, Old Test. in Jewish Church, 2nd ed., p. 266.
His eloquence was so remarkable that he was known as "the Welsh Demosthenes." His strength lay in his intense conviction of an intimate connexion between sin and punishment and in his power of dramatic presentation. As an ecclesiastic he was not so successful; he helped to compile his church's Confession of Faith in 1535, and laid great stress on a clause which required of the elect to the exclusion of all others was a stout Tory in politics and had many friends among the Anglican clergy; he opposed the movement for Roman Catholic emancipation. Several of his sermons were published in Welsh.

ELIAS LEVITA (1469-1549), Jewish grammarian, was born at Neustadt on the Aisch, a place in Bavaria lying between Nuremberg and Würzburg. He preferred to call himself 'Ashkenazi,' the German, and bore also the nickname of 'Bachurus,' the youth or student, which latter he gave as title to his Hebrew grammar. Before the end of the 15th century he went to Italy, which thenceforth remained his home. He lived first at Padua, went in 1509, after the capture of this town by the army of the League of Cambrai, to Venice, and finally in 1513 to Rome, where he found a patron in the learned general of the Augustinian Order, the future cardinal Egidio di Viterbo, whom he helped in his study of the Kabbalah, while himself was inspired by his literary work. The storming of Rome by the army of the Constable de Bourbon in 1527 compelled Elias to go to Venice, where he was employed as corrector in the printing-house of Daniel Bomberg. In the years 1541 and 1542 he lived at Isny, in Southern Württemberg, where he published several of his writings in the printing-house of the learned pastor Paul Fagius. The last years of his life he spent at Venice, continuously active in spite of ill-health and the weakness of old age. His monument in the graveyard of the Jewish community at Venice boasts of him that "he illuminated the darkness of grammar and turned it into light." The importance of Levita rests both in his numerous writings and in his personal activity. In the remarkable period which saw the rise of the Reformation and gave to the study of the Hebrew Bible and to its language an importance in the history of the world, it was Levita who furthered in an extraordinary manner the study of Hebrew in Christian circles by his activity as a teacher and by his writings. To his pupils especially belong Sebastian Minoter, who translated Levita's grammatical works into Latin, also George de Selve, bishop of Lavau, the French ambassador in Venice (1536), who was instrumental in obtaining for Levita an invitation from Francis I. to come to Paris, which invitation, however, Levita did not accept. Levita's writings on Hebrew grammar (Bachur, a text-book, 1518; Barka, an explanation, alphabetically arranged, of irregular word-forms; a Table of Paradigms; Pirke Eliephon, a description—partly metrical—of phonetics, and other chapters of the grammar, 1520; his earliest work, a Commentary on Moses Kimhi's Hebrew Grammar, 1508) were by reason of their methodical exposition, their clear articulation, their avoidance of prolixity, especially suited as an introduction to the study of the Hebrew language. Amongst Levita's other writings is the first dictionary of the Targumim (Metewgeman, 1541) and the first attempt at a lexicon in which much of the treatise of late Hebrew language was explained (Tishbi, explanation of 712 new Hebrew vocables, as a supplement to the dictionaries of David Kimhi and Nathan b. Yehiel, 1542). Scientifically most valuable, and of original importance, are the works of Levita on the Massora; his Concordance to the Massora (Sefer Zikkronot completed in the second revision 1536), of which hitherto only a small part has been published, and especially his most celebrated book Massoret Hamaasoret (1538), published with English translation in the scope of the revision of 1865 its first attempt to give a systematic account of the contents and history of the Massora. By his criticism of the Massora, and especially by proving that the punctuation of the books of the Hebrew Bible is of late origin, Levita exercised an epoch-making influence. Of his other writings may be mentioned his running commentary on David Kimhi's Grammar and Dictionary (in the Bomberg editions 1545, 1546), his German translation of the Psalms (1545) and the Basso-Buch (more properly Buroebuch, a German recension of the Italian novel Historia di BUono d'Antona, 1508).

A moorland village and water-place of Fife, lying on the shore of the Firth of Forth. Pop. 687. It is 10 m. due S. of St Andrews, but 20 m. distant by the North British railway, which makes a great bend by following the coast. Though it retains some old houses, and the parish church dates from 1569, Elie is, as a whole, quite modern and is one of the most popular resorts in the county on account of its fine golf links and excellent bathing. The royal burgh of Earlisberry (pop. 317) is situated in the parish of Elie, which it adjoins on the west. Its charter, granted by Malcolm Canmore, having been burned, it was renewed by James VI. The chief structure is the town hall, which is modern but has an ancient steeple. The place derived its name from its use by the earls of Fife as a ferry to the opposite shore of Haddington, 8 m. distant. Macduff's cage near Kincaig Point is believed traditionally to have been that in which the thane took refuge from Macbeth. Two and a half miles north is Balcarres House, belonging to the earl of Crawford, where Lady Anne Bruce (1750-1824) was born.

ÉLIE DE BEAUMONT, JEAN BAPTISTE ARMAND LOUIS LÉONCE (1798-1874), French geologist, was born at Canon, in Calvados, on the 25th of September 1798. He was educated at the Lycée Henri IV, where he took the first prize in mathematics and physics; at the École Polytechnique, where he stood first at the exit examination in 1819; and at the École des Mines (1819-1822), where he began to show a decided preference for the science with which his name is associated. In 1823 he was selected along with Dufrenoy by Brochant de Villiers, the professor of geology at the École des Mines, to accompany him on a scientific tour to England and Scotland, in order to inspect the mining and metallurgical establishments of the country, and to study the principles on which Greenough's geological map of England (1820) had been prepared, with a view to the construction of a similar map of France. In 1835 he was appointed professor of geology at the École des Mines, in succession to Brochant de Villiers, whose assistant he had been in the duties of the chair since 1827. He held the office of engineer-in-chief of mines in France from 1833 until 1847, when he was appointed inspector-general; and in 1861 he became vice-president of the Conseil-Général des Mines and a grand officer of the Legion of Honour. His growing scientific reputation secured his election to the membership of the Academy of Berlin, of the Academy of Sciences of Paris, and of the Royal Society of London. By a decree of the president he made a senator of France in 1852, and on the death of Arago (1853) he was chosen perpetual secretary of the Academy of Sciences. Élie de Beaumont's name is widely known to geologists in connexion with his theory of the origin of mountain ranges, first propounded in a paper read to the Academy of Sciences in 1829, and afterwards elaborated in his Notice sur le système des montagnes (3 vols., 1852). According to his view, all mountain ranges parallel to the same great circle of the earth are of strictly contemporaneous origin, and between the great circles a relation of symmetry exists in the form of a pentagonal réseau. An elaborate statement and criticism of the theory was given in his anniversary address to the Geological Society of London in 1853 by William Hopkins (Quart. Journ. Geol. Soc.). The theory has not found general acceptance, but it proved of great value to geological science, owing to the extensive additions to the knowledge of the structure of the earth's crust which it encouraged and the facts it found to support it. Probably, however, the best service Élie de Beaumont rendered to science was in connexion with the geological map of France, in the preparation of which he had the leading share. During this period Élie de Beaumont published many important memoirs on the geography of the country. After his superannuation at the École des Mines he continued to superintend the issue of the detailed maps almost until his death,
which occurred at Canon on the 21st of September 1874. His academic lectures for 1843-1844 were published in 2 vols., 1845-1849, under the title *Leçons de géologie pratique.*

A list of his works was published in the *Ann. des Mines,* vol. vii. 1873, p. 259.

ELIJAH (a Hebrew name meaning "Yahweh is God"), in the Bible, the greatest and sternest of the Hebrew prophets, makes his appearance in the narrative of the Old Testament with an abruptness not out of keeping with his character and work (1 Kings xvii. 1). The first and most important part of his career lay in the reign of Ahab, i.e., during the first half of the 9th century B.C. He is introduced as predicting the drought. God was to send upon Israel as a punishment for the apostasy into which Ahab had been led by his heathen wife Jezebel. During the first portion of this period Elijah found a refuge by the brook Cherith, "before the Jordan." This description leaves it uncertain whether the brook was to the east of Jordan in Elijah's native Gilead, or—less probably—to the west in Samaria. Here he drank of the brook and was fed by ravens, who night and morning brought him bread and flesh. When this had dried up, the prophet betook himself to Zarephath, a Phoenician town near Sidon. At the gate of the town he met the widow to whom he had been offering sticks for fuel. This preparation, she believed was to be her last meal. She received the prophet with hospitality, sharing with him her all but exhausted store, in faith of his promise in the name of the God of Israel that the supply would not fail so long as the drought lasted. During this period her son died and was miraculously restored to life in answer to the prayers of the prophet (1 Kings xvii. 8-24).

Elijah emerged from his retirement in the third year, when, the famine having reached its worst, Ahab and his minister Obadiah had themselves to search the land for provender for the royal stables. To the latter Elijah suddenly appeared, and announced his intention of showing himself to Ahab. The king met Elijah with the reproach that he was "the trouble of Israel," which the prophet boldly flung back upon him who had forsaken the commandments of the Lord and followed the Baalim. The retort was accompanied by a challenge—or rather a command—to the king to assemble on Mount Carmel "all Israel" and the four hundred and fifty prophets of Baal. (The four hundred prophets of Ashtaroth have been added later.) From the allusion to an "altar of Jehovah that was broken down" (1 Kings xviii. 30) it has been inferred that Carmel was an ancient sacred place. (On Mount Carmel and Elijah's connexion with it in history and tradition see CARMEL.)
